THE

CIVIL ENGINEER

AND

ARCHITECT'S

JOURNAL.

FROM OCTOBER, 1837, TO DECEMBER, 1838.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 57, KING STREET, WESTMINSTER;

H. HOOPER, PALL MALL EAST; GROOMBRIDGE, PANYER ALLEY, PATERNOSTER ROW; J. WEALE, 59, HIGH HOLBORN; J. TAYLOR, 1, WELLINGTON STREET, STRAND; J. WILLIAMS, 106, GREAT RUSSELL STREET, BLOOMSBURY; WRIGHTSON AND WEBB, BIRMINGHAM; LOVE AND BARTON, AND THOMPSON, MANCHESTER; WILMER AND SMITH, LIVERPOOL; BAINES AND SON, LEEDS; H. DEIGHTON, WORCESTER; RIDGE AND JACKSON, SHEFFIELD; J. SUTHERLAND, EDINBURGH; YOUNG, DUBLIN; JACKSON, NEW YORK.

PREFACE.

We feel happy in reaching the conclusion of our first volume, not from dissatisfaction with the task, but from the conviction that as we have done our duty hitherto, that so we have a similarly useful career guaranteed to us for the future. To the work itself, and to our own exertions we will allude presently; but first, we think, we cannot better introduce this volume than by offering a short abstract of the progress of the two professions in the current year, of which our labours present a register, and in summing up which it will be seen how far we have performed our duty to the public, and fulfilled the pledges under which we commenced this undertaking. This review is, perhaps, the more necessary, as it enables us to ascertain what events belong to this particular epoch, and to compare the present period with its predecessors. That the annals of this year, although many resources have been cut off by financial difficulties, are neither wanting in importance of themselves, nor as relatively to other portions of this century, the great development of steam navigation and railways evidently proves, while they contribute extensively to the character of an age which may justly be marked among the eras of human civilization. Wonders, succeeding wonders, pass before our eyes, and each by its gradation serves but to weaken the impression of its successor, they become as it were in the period of their performance diluted from their strength; and it is only therefore when they become matters of the past, that the eye can take in at one view the whole immensity of the subject, and appreciate its greatness. It is this feeling which induces us to look with pleasure upon the bright epochs of the bygone day, and after classing the events of our own existence with those of the darker periods, we wish that it were our lot to exist in days when poets trod the same ground, and science heralded its greatest triumphs. It is not that we are insensible to the progression of the age, but that like a man growing gradually rich by regular labour, we feel our possessions less in comparison with one who suddenly acquires wealth. It is by such defects of the human mind that in hankering for the glories of the past, and losing the enjoyment of those of the present, we become dull to the emotions of an era, which as it is gradually sweeping away all the labours of former ages, so by these very effects it is surpassing them in grandeur. If we look back to our own golden days, to Pope, Milton, Shakspeare, we find nothing that obscures in importance the present, and it is only by comparing this latter with the European era of the Restoration of the arts, called by us the Reformation, that we are able to appreciate its importance and ascertain its value. That restoration acted powerfully on mind and matter; it recovered the riches of Greece and Rome, and perpetuated that knowledge by the printing press, while on the ocean it armed and guided the adventurous seaman. It aroused the old world from its slumbers, and called into existence the new; it shook to the foundation the knowledge and belief of the multitude, and forced into life new modes of reasoning and of thought. This is a summary which no former secular eras of the world can present, for while this tells of restoration and new life, they relate only the history of ruin and desolation, and the bending of luxury to barbarism and darker ignorance. On our side, if we derive much from the efforts of the past, it is no derogation from our claims to distinction, it is an inheritance and a possession as much as the glories of Greece and Rome, from which the age of the restoration derived lustre, and delegated it to posterity. In the present day the current of the Mississippi and the storms of the Atlantic have been overcome, the speed of the animal creation surpassed, and the resources of the vegetable kingdom supplied from the bowels of the earth—the whole human race knit in closer bonds of connection, nations converted into townsmen, and distant countries into neighbouring provinces, while the prejudices of locality have received a fatal and an unexpected blow. The steam boat flies in a safer path than the ship guided by the compass, and the powers of cannon and gunpowder bid fair to be abolished with the vessels which they armed. The same fluid which spins clothing in England for the majority of the inhabitants of the earth, has given to the printing press an impetus by which all its former properties of communication are lost in the shade of insignificance. The new world which our ancestors gave to us has been brought within a fortnight's journey of our shores, and the preponderance of civilization irrevocably secured. Another world has sprung up in Australia, and Polynesia is forming new nations as it once did islands. Chemistry has advanced into a science, geology has peopled and discovered unknown worlds, and electricity has developed powers which will give fresh resources to the human race. These are triumphs in which our own nation, nay, we ourselves have participated, and which will confer lasting glory on our country and lustre on the age, while the future historian will look back with envy to a period when a new destiny was created for mankind, and in which the performances of ancient times were crumbled to oblivion within the very period of the creation of the new. These things are works of the present century, and most of the last score years, and they are but types and precursors of what within our own lifetime must yet be done. It must be pleasant, therefore, to anticipate the future annalist, and contemplate what we have contributed within our present day. Other departments of art and science can doubtless

furnish their quota to the labours of the age, and although Dickens, Knowles, Bulwer, Talfourd, and Marryat, have sustained the honours of letters, and Chantrey and Wilkie those of art, yet we cannot but think that to the historian and the philosopher the works of our influential professions are neither unworthy of comparison in their merit, nor unimportant to the records of the age. In fulfilling this necessary duty, and in order to present a clearer view of the subject, we shall first consider the material operations, and then advert to the more literary portions of the subject, while we shall, as a matter of courtesy to the elder of the two professions, give the precedence to the works which come under that department.

The labours of architects this year have been extensive, but few great public buildings have been erected on account of those of greater importance being still in progress. Among the Government edifices completed have been the Juvenile Penitentiary in the Isle of Wight, and the Judges' Chambers in Serjeants' Inn; but neither are entitled to any architectural rank. The municipal erections include a Guildhall at Penzance, Market-places at Merthyr Tydvil, Brecon, and Helstone, and the Assize Courts at Devizes. The more prominent charitable institutions are the Royal Berkshire Hospital and that at Plymouth. The chief buildings for purposes of science or public instruction, have been the Polytechnic Institution in Regent-street, a new façade to the Royal Institution, the City of London School, the Derby Athenæum, and the Blind School in the Borough. The commercial edifices have been various, and among them the most worthy of notice are the London and Westminster, and the Manchester and Salford Banks, with the Globe and Legal Assurance Offices. The entrance to the London and Birmingham Railway affords an example worthy of the imitation of the other companies having depôts in London. Some artistical contribution to the grandeur of the metropolis is surely due from those who derive so much profit from it, and at least not to allow their stations to appear mere mercenary booths where they ought to be the greatest ornaments. The ecclesiastical structures have been numerous, but we regret that a mistaken spirit of economy has rendered them anything but additions to the architectural riches of the country. When money is taken from the public some sacrifice is due to the national glory and the public gratification, and we are not actuated by any professional bias in saying that some degree of liberality would afford satisfaction to the people and honour to that Church, to which we are indebted for so many noble monuments. A similar spirit of parsimony, but still more reprehensible, has been exercised with regard to the Union Workhouses, and we regret that in this, as in so many other instances, the Commissioners should give such countenance to the ideas of grinding and oppressive avarice which are too commonly attributed to them; indeed, we should have thought it wiser to have relieved themselves from the stigma of reducing the comforts of the poor, rather than to have aggravated it, by endeavouring to bate down the rewards of intellect, and in architecture and medicine seeking science at the lowest rate of degradation to which the necessities of the professors could compel them to submit. We beg to remind both church builders and poor law guardians, that however desirable it may be to have science cheap, and however much we might wish that gold was as abundant as lead, that talent and gold from their rarity will maintain their price, or leave only a substitute in pinchbeck and ignorance. New cemeteries have been opened in different parts of the country, among which one of the finest is the North London, looking down from the Highgate hills on the modern Babylon. The taste for these establishments and for botanic and zoological gardens is rapidly extending, and their successful progress cannot fail to influence greatly both the physical and mental health of the great mass of the population. Of buildings devoted to pleasure, the finest is the Oxford and Cambridge Club. Among the more striking foreign works have been the Arc de l'Etoile at Paris, and the Arco della Pace at Milan (both works commenced by Napoleon), the Church of Loretto at Paris, Girard College (Philadelphia), and the Hungarian Museum at Pesth. While so many noble works have increased the treasures of art, we have to lament on the other hand the loss of several older monuments, although this regret is diminished by the preparations going on for supplying their loss by finer edifices. The destruction of those by fire in the last winter seems to have been caused by accidents arising from the rigour of the weather; and among them were the Royal Exchange in London, the Winter Palace at St. Petersburgh, the Opera at Paris, the Church of Hoorn, and the New York Bowery Theatre. Considerable attention has been bestowed on the restoration of old works, judicious repairs having been executed at Bristol, Christ Church, Winchester, and most of the ecclesiastical edifices in the country, while the use of Saxon in the churches at Tunbridge Wells and Cardiff will, we hope, restore to notice this long-neglected style, so rich in historical associations. Coincident with the revival of this style is the introduction of that of the Renaissance from France, on which we seem to be dependent for internal decoration. We have recently borrowed the tinsel of Louis Quatorze, and because the French have at last awakened to a knowledge of the Gothic, we are now to be overwhelmed with the frippery of the Renaissance. The trumpet has already been sounded, and it will follow as a matter of course, that in the rage of passion the English florid style will be debased below its French contemporary. We regret this imitation of bad masters which pervades our aristocracy, and we can only attribute it to the feeling which illumines with a halo a pilgrimage to the tomb of Virgil or the residence of Voltaire, and makes us forget that in our own metropolis, Milton, a greater man, was born and sepultured. If Gothic must be had, and at such a period, the banquetting halls of Henry the Eighth or of Wolsey will furnish quite as good materials as those of Louis the Twelfth or Francis the First. We suppose that the result of this mania will be to change the style of fresco painting, upon which many of our artists have been engaged this year, and perhaps to supplant the Arabesques of Pompeii for those of Giulio Romano. As the Bavarians have employed fresco abundantly in the interior of their edifices, so this year, under the name of Lithochromy, they have restored the Egyptian and Greek mode of colouring the exterior. The Jews have recently taken a more prominent position with regard to the arts, and the beauty of many of the decorations in the New Synagogue, in Great St. Helen's, affords a good practical commentary on the puritanical aversion to ornament of many of our clergy. A novelty this year has been the erection of a colossal statue to the Duke of Sutherland, in Scotland, emulating the works of Egypt, while we perceive with pleasure that at Edinburgh they have adopted the union of an architectural design with that of a statue to commemorate Sir Walter Scott: and we sincerely trust, that in the plan for a testimonial to the immortal memory of Nelson, the community of the arts will not be forgotten.

Having thus dismissed the subject of Architecture we shall commence that of Civil Engineering, by examining the proceedings of Government on the subject. We shall first refer to the standing orders of Parliament on Public Works, from which, we regret to state, the evil effects anticipated by practical men have fully resulted; and, indeed, it could not be otherwise, when some few ignorant theorists affected the vitality of commercial enterprise, by attempting to destroy a minor evil. The consequence of these regulations has been, that no great work has been offered for public sanction this year, and many have been delayed or abandoned from the absolute impossibility of complying with the absurd restrictions on the means of raising the capital. In addition to these unfortunate proceedings, an equally uncalled for impediment has been opposed to public enterprise in Ireland, by the recommendations of the Government Irish Railway Commission, which appears to have equally attacked the Government and the Public; for as the latter were discouraged by its misrepresentations, so the standing orders of the former were pointed out as incompatible with all sound reasoning and practical operation. In France, on the other hand, the people have gained by defeating the Government in the attempt to obtain a monopoly of the Railways, and have thus probably laid the foundation for the successful operation of the joint-stock system in France, a system which, in this country and the United States, has effected works and created resources, before which those of any country are insignificant. Among other pieces of jobbing contemplated at the expense of the public works of this country, is a pernicious piece of quackery in the shape of appointing inspectors of steam-boat engines, as if they were more worthy of surveillance than other classes of shipping, when the result of such interference must be to place this great arm of the country at the mercy of Government theorists and police chicanery. Too many recent instances have occurred in this country of the evil effect of Government interference, direct or indirect, and we have little doubt that the authorities would interdict any obnoxious invention with the same spirit in which they deprived Southey and Byron of their copyright, and branded the greatest of our modern poets as atheists. We regret to see that the authorities at Washington, with their characteristic disposition for meddling wherever they have an opening, have managed to obtain a similar control in the United States, and with about as much reason. It is well that the laws should be made stringent for criminal neglect—for that every man knows his responsibility; but it never succeeds to subject a mass of men to the ideas and opinions of a few; but on the contrary annihilates all emulation, and promotes a spirit of servility and degradation. The Ordnance and Tithe Surveys have been carried on with greater vigour; but we cannot but regret that a truer spirit of economy had prevailed, and a greater regard to the early completion of works so important to engineering. A geological survey ought to have been carried on simultaneously, and the surveys for Boundaries and Tithes united, by which large sums would have been saved and the objects better attained. The delay has been caused, according to the opinion of some, by the want of a greater number of officers; but we must observe that there would have been no difficulty in obtaining a competent supply of civilians, as is done in other countries. The Act passed to regulate the Conveyance of Mails on Railways, although rather premature, has been made less injurious in its enactments than was originally proposed; but we earnestly wish that the Administration, when they endeavour to obtain so many sacrifices, avowedly on account of the public, would take more effective measures to render that department useful to the public, as it now presents great obstacles to the diffusion of science and the interests of trade. We regret, that although some discussion has taken place on Copyright, and amended laws have been made to protect mental property, that no improvement has taken place in the law of Patents, but that it still remains more barbarous and ineffective than that of any nation of Europe, and is infinitely surpassed by the legislation even of the Spaniards. We take great pleasure in instancing, as an act of liberality, the grant, by the American Congress, of 100,000 dollars to the heirs of Fulton, while, in our country, the only honours bestowed upon the profession have been statues to Watt, at Greenock and at Manchester.

In the enumeration of the works completed this year, the subject of Railways will necessarily claim priority, and particularly as exhibiting one of the most important features; for although we have already had sufficient of these works to appreciate their merit, it is only at present that we begin to enjoy anything like extensive advantages from them. The road is now completed, by the Birmingham, Grand Junction, and North Union Railways, to Preston; and while the Southampton, Great Western, and Hayle Lines have been partially opened, those of the Newcastle and Carlisle, London and Greenwich, Manchester and Bolton, Newtile and Glammis, and Dundee and Arbroath, have been completed. The American Railways have been very much impeded by the financial difficulties of that people; but in other extra-insular countries great progress has been made. The Belgian Railways have been extended, and lines have been opened from Paris to St. Germain, from Dresden to Leipsic, from Vienna northwards, from Berlin to Potsdam, and at Havannah, in the Isle of Cuba. We regret that their operations have been accompanied with many serious accidents; but it is to be observed that, while they are not more severe nor more numerous than those incident to other methods of travelling, they are such as, being attributable to newly organized undertakings, will be diminished with the steady progress of this means of communication.

With regard to Canals—having attained their greatest development, they must necessarily remain stationary, and present us with few remarks. A Grand Tunnel, however, has been opened on the Birmingham Canal at Cozely, near Bilston, and the Ulster Canal in Ireland, and the Laonine in Canada, have been opened for traffic.

Many Bridges have been finished in different parts of the country: but, except that at Sockburn over the Tees, none of any extent. Several Steam Floating Bridges have been erected in the South of England, and are found to present a cheap means of communication. Repairs to some extent have been made of the bridges over the Thames, and the Brighton Chain-pier; and accidents have occurred to several Suspension Bridges at home and abroad, from weather, and during the course of trial, among the latter of which is that at Freyburg.

Several Harbours are in progress or contemplation, but little of importance has been done this year. A long Sea-wall has been constructed at Hastings, and a River-quay at Woolwich, and several minor works in different sea ports.

A prominent feature of the year is, undoubtedly, the extension of Steam Navigation, and the successful result of the passage to America. This line of traffic is now placed on a firm basis, and its effects on the intercourse of the two kindred countries must speedily become of the utmost interest and importance. Independently of the general increase of this

means of navigation, a direct communication has been established between London and St. Petersburgh, with Madeira, and with our possessions in the East: it has been extended in Portugal and the Brazils, and to the rivers Meuse and Nile. In the construction of the vessels a similar impulse has taken place. Steamers of a large class, as the Great Western, British Queen, and Liverpool, have enhanced the importance of our mercantile marine, while a considerable increase has been made in the employment of iron steamers at sea and on the rivers. Steam Naval Architecture has been elevated into a regular art, by the labours of the engineers and the works of its authors, while important experiments have been made to effect its improvement. The Columbus Quicksilver Steam boat for some time attracted public attention, but nothing of importance has yet been done, and in the meanwhile the Archimedean is carrying out the result of a series of theories and experiments, commenced by Trevithick, to obtain motion by placing the propelling power at the stern of the vessel. Steam ships of war have acquired fresh importance, and the different Governments of the world have directed their energies towards the improvement of this arm of warfare, of which the success of the English in Portugal and at St. Sebastian's have shown the importance. These vessels have been armed in a more formidable manner, and the Government has regularly adopted them into its service, by giving their engineers relative rank with the several classes of warrant officers of the old navy. We should suggest, in addition, that mechanics form a regular part of the instruction by the newly introduced naval instructors; and that an examination on this subject be added to the qualifications for passing as a lieutenant. Among the incidents of the increase of steam traffic have been several dangerous explosions of vessels, respecting which the public mind has been unnecessarily agitated. We believe that these occurrences are less attributable to any faults of the parties concerned, than to the infant state of the science, which does not allow that accuracy which is consequent on a longer experience. Thus, for instance, it is known that locomotive engines from the same maker will vary to a great degree in their performances, beyond the exertions of any precaution or skill to ensure uniformity; and, indeed, it appears hard to require perfection in such enlarged machines, when even in the little watches which we daily observe we cannot check irregularities. At any rate, from the examination of men of the greatest experience, it appears impossible by any superintendence to effect that which can only be the result of the advancement of science.

Mining has presented several novel features, of which the more remarkable have been the utilization of anthracite coal, the application of the hot blast, and the introduction of asphalte. Little more as yet has been done with regard to the employment of this latter, than laying down some experimental pavements, which appear to have worn well hitherto. As an aid to the progress of mining, we may instance the extension of schools for instruction in that branch, to which we shall have farther occasion to allude in a subsequent part of this review.

Having dismissed these portions of the subject we will now proceed to ascertain what has been the progress of the professions in contributing to and maintaining the stores of knowledge left by our predecessors. We find among the books published many that do honour to the public spirit of their publishers, and which will stand in honourable rivalry with any of their predecessors; but we perceive on this as on previous occasions a paucity of volumes on the subject of Architecture. In our pages will be found Reviews of Tredgold on the Steam Engine and Naval Architecture; the Public Works of Great Britain, by F. W. Simms; the Port of London, by James Elmes; N. Wood, on Railways; the Transactions of the Institution of Civil Engineers; Papers, by the Corps of Military Engineers; several Works on American Engineering; Railway Practice, by S. C. Brees; Britton's Dictionary of the Ancient Architecture of Great Britain; and Dr. Ure's Dictionary of Arts, Manufactures, and Mines. A new class of literature has been created by the extension of Railways, directed to topographical descriptions of the country through which they pass, and it is most probable that the number of these works both here and abroad will extend the limits of topographical knowledge.

The several societies devoted to the promotion of professional objects have continued their useful careers, and greatly contributed to the accumulation of practical knowledge. To the proceedings of the Institution of Civil Engineers we have had occasion to allude, and numerous communications have been addressed to the Royal Institution of British Architects, the Architectural Society, and that at Manchester. The Mechanical Section of the British Association bestowed their usual attention on Engineering objects, although we should be better gratified by seeing their proceedings attain a character of more practical importance. The Royal Academy, being principally devoted to the imitative arts, have never been able to afford those facilities to Architecture which it imperatively demands; but the small space which they are enabled to reserve for an exhibition on this subject has been fully occupied by the zeal of the rising architects. Among the events important to the Arts is that of the great extension of the Museums this year, although we cannot refrain from pointing out the unnecessary seclusion of the Soanean Collection, the principal Architectural Gallery of the country. The East India Museum has disclosed some interesting representations of Oriental edifices, and the Hampton Court Gallery allows the public access to greater treasures of art than were ever before offered to their contemplations. A new Subscription Mechanical Museum, on the plan of the Royal Gallery of Science, has been opened at the Polytechnic Institution, and affords by its proceedings a new proof of the rising predilection for practical science. We should like, while mentioning the subject of institutions, to suggest that, as we have already a Museum of Antiquities, and a Gallery of Pictures, that the Soanean Collection could not be more appropriately dedicated than as a repository for models of architectural works, many of which are already exhibited there, and there are others of interest dispersed in various parts of the metropolis. Nothing, for instance, could be more pleasing than to trace the progress of St. Paul's from Wren's first sketch to the finished building, and we are sure that to such an object the profession and its institutions would contribute with pleasure. In this manner, in the Bodleian Gallery, at Oxford, the middle of the rooms is occupied with models of the finest remains of Greek and Roman edifices, arranged so as to become objects of prominent interest.

The progress of professional education has received a sudden impulse, and is placed on a basis, which equally tends to augment its real value, and its estimation in public opinion. The University of Durham has been the first to include among its faculties courses of Civil Engineering and Mining, and this example has been pursued in London by University and King's Colleges. The establishment of a School of Mining at Durham, and the intended foundation

of another in Cornwall, will tend to remove those difficulties which stood in the way of any attempt to form a central School for the whole country, and the nation will be relieved from the reproach—if, indeed, our mining rank does not relieve us from such an imputation—of being neglectful of instruction in this branch of industry. The Irish Railway Report shows in what manner the Agricultural School at Templemoyle has acted as a School for surveying in Ireland, while at Dublin the Royal Society have long maintained a School of Agriculture and Mining. Elementary Instruction in Art has also acquired an unexpected importance, and the Schools of the Society for Promoting Practical Design, and those at Manchester and Newcastle have fully shown the practicability of imparting instruction in design to the artisan, and his anxiety to acquire it. While, however, education has attained this development, we must entreat its promoters to be cautious not to give too great scope to the theoretical, nor to neglect those practical modes of instruction by which we have attained so much eminence, and by which we shall most consult the genius of our people. The system of teaching by lectures, it has been found by experience, cannot successfully inculcate everything; and while it has been abandoned at our older universities, in medical studies it is accompanied by demonstrations and clinical instructions, such as can never be applicable to mines or engineering. We can have no dead railways to dissect, nor prepared veins and lodes to illustrate, and although construction may be partially learned from models, yet it is in the open field of practice that its application must be acquired. While we recognise with pleasure this tribute to science, and this improvement on university education, there is one point we should suggest, which, as it interests the public and not the profession, we are the more prompt to consider worthy of attention in the present propitious crisis,—it is the adoption of that system of instruction in artistical antiquities which is equally recommended by our classical sympathies, and by the opinions of some of our most talented writers. At the same time we should recommend that, as the universities have adopted a new faculty, so they should not leave it the only one without honours; but that, as Literature, Medicine—nay, Music—have their degrees, that here, as in foreign universities, philosophy may equally have its doctorate, and science not remain the only muse untitled and unused.

Having thus, at some length, given a review of the leading transactions of the year, or, if we may so term it, a report on the annals which have been confided to our keeping, we feel less diffidence in alluding to the manner in which we have fulfilled our duty towards our supporters of the two professions. We set out with the determination to be, as far as in our power lay, impartial towards all; and we trust that as we have not been subservient towards any faction, so, on the other hand, we have never unwarrantably attempted to suppress the opinions of others. The author, under the excitement of affection for his work, may sometimes have thought our criticism too severe; but we feel justified that while we have not pandered to the evil feelings of the crowd, the continued support of the public has confirmed us in the views we have taken. While we have constantly endeavoured to repress whatever we thought unworthy of the public notice, we have with the same feeling earnestly endeavoured to elevate the standard of professional excellence, and to protect the character and interests of the professions from the attacks of ignorant prejudice, or the assumptions of foreign rivalry. In communicating information it has been our particular care to limit ourselves to the practical, and to incur the complaint of dryness from the profession, rather than that of ministering to theorists or amateurs. On the other hand, we trust that the immense mass of matter condensed into close compass is free from the reproach of dullness, or of neglect of the higher mental branches, which are the distinction of professions connected with genius and the liberal arts. As we have omitted no means, either by compilation, translation, or by original contribution, to afford satisfaction to our readers, so we feel confident that the quantity of information laid before them will fully assert our disposition to do our duty. In the volume which we now close are above four hundred pages and two hundred engravings, presenting a mass equal to nearly two thousand magazine pages, or eight volumes of octavo novels, and containing a quantity of periodical information not heretofore presented to the two professions. That our labours have been appreciated, the increasing support of our readers has shown, while the attention which we have received from our English cotemporaries and from foreign editors, has afforded a sufficient testimony of our own standing, and of the manner in which we have performed our duties toward the public at large.

We trust that our exertions have been received with that satisfaction which it has been our honest endeavour to afford; and as we are conscious of no dereliction of duty, so we are unaware of any reproach. As it has been our fixed principle to adapt our work to the wishes of our readers, and not to warp it to private purposes, we have been particularly cautious in acceding to any change which we believe was uncalled for by circumstances, or dissatisfactory to our supporters: it is for this reason that although repeatedly importuned, we have steadily resisted any suggestion for increasing the expense of the Journal. It has been observed to us, however, that in the present deficiency of architectural periodicals, it would be productive of great convenience to the profession if we were to devote a larger space to the communication of such information than our present limits permit us to afford. Under such circumstances, should it appear to meet with the general concurrence of our readers, we would publish quarterly, at sixpence, an additional sheet, or an engraving of a public building. For ourselves, however, we candidly admit that we are perfectly satisfied with our present progress, and shall only, in compliance with such disposition for a change, take measures to increase the amount of our labours.

To our numerous contributors the prompt attention we have on all occasions shown will be a sufficient proof of our recognition of their services; but we cannot conclude this volume without especially thanking them for the essential advantages which their talents and abilities have, on many occasions, afforded to the Journal, and at the same time assuring them that we shall always derive gratification from a continuance of their support. To the professions at large we generally appeal to afford us information on whatever comes under their notice; and to the architects in particular we rely for contributions on the extension of the Journal, for as it will be mainly devoted to their objects, so it will be incontestably entitled to their support.

In conclusion, we place before our readers the result of our labours, and trust that, as we have endeavoured to merit their patronage, that so our exertions may for many future years entitle us to its continuance.

THE

CIVIL ENGINEER AND ARCHITECT'S

JOURNAL.

AMERICAN RAILWAYS.

The construction of railways in this country being the all-absorbing subject of the day, and various plans having been lately introduced for laying the rails on continuous sleepers, we determined at the outset of our work to introduce the several systems of construction adopted in America; for which we are indebted to a work lately published in Paris, and edited by Gme. Tell Poussin. We have had the whole of this work translated, and had intended to go more fully into the subject; but the press of other matter prevented us giving more than that portion which relates to the construction of railways, and which we consider to be of the greatest value. The work enters into a full description of the whole of the American Railways, describing the country, engines, companies, expenses, administration, and legislative documents, some of which we shall hereafter allude to.

The whole of the rails are placed 4 ft. $8\frac{1}{2}$ in. apart throughout the following figures:—

Fig. 1 is a section of the railway adopted on the Boston and Providence line.

Fig. 1.

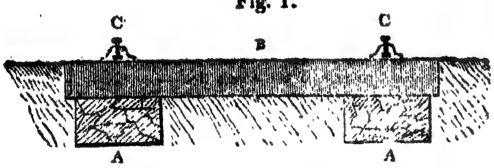

Fig. 2.

Parallel holes A are excavated at intervals of 4 feet from centre to centre, 1 foot 6 inches square, and filled in with broken stone 1 foot deep; upon which are laid transverse timber sleepers B, 6 feet 6 inches long, and 8 inches square. The rails, fig. 2, are of wrought-iron, weighing 60 lbs. per yard, similar to the English rails, fixed in cast-iron chairs, as shown in fig. 3, weighing ten pounds, and spiked down to the sleepers.

Fig. 3.

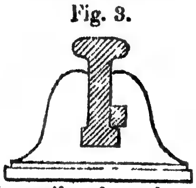

Fig. 4 is a section showing the mode of laying the rails adopted on the Jamaica and Brooklyn line, in Long Island. Instead of transverse bearers, or longitudinal sleepers, vertical pieces of timber A of acacia, larch, white oak, pine, or chestnut, about 12 inches diameter and 3 feet in length, are let into the ground the whole depth, with the largest end downward; the soil is then puddled round them, and they are sawn off level with the under side of the rails. They are placed 3 feet apart from centre to centre; every other pair are connected by a light iron bar, B, let in level with the top, and attached by cramps; the surface of the blocks is coated with hot tar or pitch; the rails are fixed immediately on the top of the blocks. This mode of construction is very economical, and calculated to last fifteen years before any of the blocks require replacing.—[It would be far better if the vertical pieces were fixed with the smaller end downward, they would then act like a wedge.—*Editor.*]

Fig. 4.

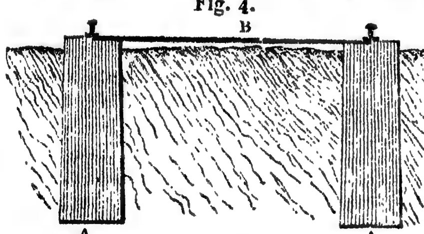

Fig. 5 is a section of the railway from Amboy to Camden, in the State of New Jersey. They have adopted the English system, by using stone sleepers, 2 feet square, and 10 inches deep, which are bedded in a mass of concrete or broken stone, 4 feet apart from centre to centre. The rails are of wrought-iron, in 16 feet lengths; a section is shown in fig. 6; width of top $2\frac{1}{4}$ inches, base $3\frac{1}{2}$ inches, narrowest part $\frac{1}{2}$ inch, and height $3\frac{1}{2}$ inches; weight, 40 lbs. per yard. The rails are fixed without chairs, resting upon the stone sleeper, and fastened down with strong cast-iron pins let into the stone between two wedges of wood. A thin piece of wood is placed between the rail and the sleeper, to break the direct concussion of the locomotive engine.

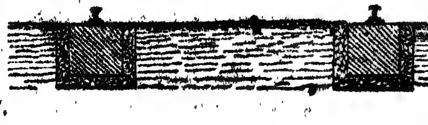
Fig. 5.



No. 1.—October, 1837.

Fig. 6.

Fig. 7 is a section of the railway from New York to Paterson, across marshy or swampy land. Holes A are dug in two parallel lines, 3 feet apart from centre to centre, 1 foot 6 inches square, and 2 feet 6 inches to three feet deep, filled in with broken stones, such as are used for M'Adamized roads. Upon these are laid transverse bearers B, of cedar or acacia wood, 8 inches square and seven feet long, on which are fixed longitudinal plates C, 6 inches by 8, bearing on the top of their inner edge rails of wrought-iron flat bar, $2\frac{1}{4}$ wide and $\frac{1}{2}$ inch thick, weighing 12·60 lb. per yard.

Fig. 7.

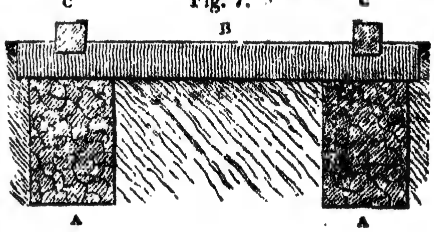


Fig. 8 is a section of the railway between Philadelphia and Baltimore. Parallel trenches A are excavated the whole length of the railway, 1 foot 6 inches wide, and 1 foot 2 inches deep; they are filled up with broken flints well rammed down, upon which are bedded the sleepers B, 10 inches wide and 4 inches thick, of spruce or other timber; on these are laid transverse bearers C, 6 feet 6 inches long, and 8 inches square, placed 3 feet apart from centre to centre, and fastened to the sleepers by keys. On the top are caulked down longitudinal plates D of oak, 6 inches square; on the edge of which is a flat wrought-iron rail, $2\frac{1}{2}$ inches wide, $\frac{5}{8}$ of an inch thick, and in lengths of 15 feet, weighing 15·75 lb. per yard: each rail is fastened by 12 nails.

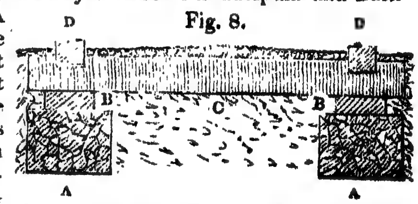
Fig. 8.



On a portion of the line they have adopted a different construction, as shown in fig. 9. Stone sleepers A, 1 ft. 6 in. by 1 ft., and 1 ft. high, are bedded in gravel or sand sunk in a hole, 2 ft. by 1 ft. 6 in., and 1 ft. 4 in. deep, at intervals of 3 ft. from centre to centre; and on the sleepers are laid the plates B, 6 in. square, secured by cast-iron chairs, spiked down: the rail is similar to that in last figure.

Fig. 9.

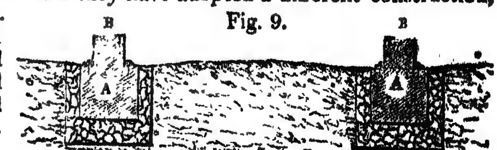


Fig. 10 is a section of the railway from Portsmouth to Roanoke, adapted to alluvial soils. Transverse sleepers A of oak, 8 ft. long, 8 in. wide, and 1 ft. deep, are buried in the ground, 5 ft. apart from centre to centre, on which are caulked down the longitudinal plates B of yellow pine, 5 in. wide and 9 in. deep; on the edge are laid flat wrought-iron rails, $\frac{1}{2}$ an in. thick and 2 in. wide, weighing 10 lbs. per yard. The transverse sleepers are hollowed in the centre, so as to allow a gravel road on the top for the use of horses.

Fig. 10.

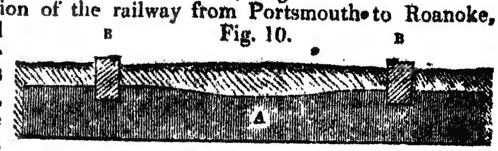

Fig. 11 is a plan, showing one of the lines of the railway from Baltimore to Washington.

Fig. 12 is a transverse section; and Fig. 13 a side view.

Fig. 11.

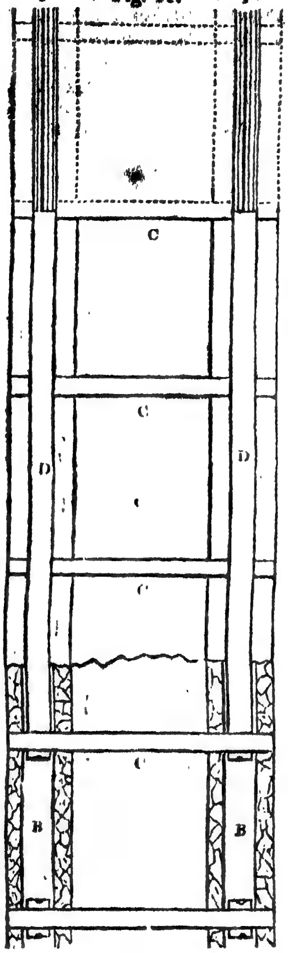

Fig. 12.

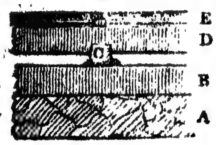
Fig. 13.



Parallel trenches A are cut the whole length of the line, 1 ft. 6 in. wide; these are filled in to the depth of 8 in. with broken stones, forming a foundation for the longitudinal timber sleepers B, 6 by 7, upon which are laid transverse bearers C, 7 ft. long, 4½ square, at intervals of 4 ft. from centre to centre; on the top are caulked down longitudinal plates D of timber, 6 in. square, upon which are fixed wrought-iron rails F in 15 ft. lengths, 3½ in. wide at base, and only 2 in. high, just sufficient to clear the wheels of the carriages: the rails weigh 30 lbs. per yard.

Fig. 14 is the plan of a double line of railway from Lowell, in the State of Massachusetts. The width of the railway for the two lines in the cuttings is 30 ft., and where it is constructed on a scaffolding, 23 ft. 6. in.; the space between the rails in the centre is 6 ft.

Fig. 14

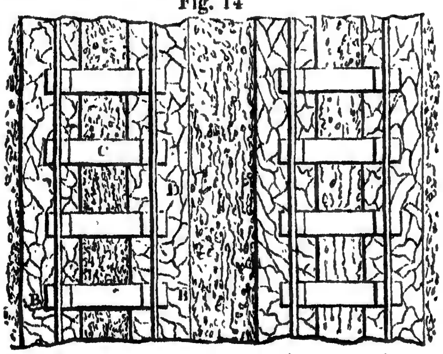


Fig. 15 is an enlarged section of one of the lines. Parallel trenches A are excavated, 2 ft. 6 in. wide, and varying in depth from 2 ft. 6in. to 3 ft.; they are filled in with broken stone, and on the top are bedded granite sleepers B, 1 foot cube each, and 3 ft. apart; guide pieces C of timber, 8 ft. long, 1 ft. wide, and 6 in. high, are placed transversely between the granite sleepers. The rails D are of wrought-iron, similar to the Liverpool and Manchester rail, weighing 40 lbs. per yard; they are in 12, 15, and eighteen feet lengths, and fixed with iron keys in cast-iron chairs, weighing 16 lbs. each.

Fig. 15.

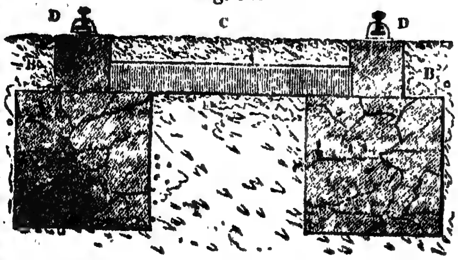

Fig. 16 is a section of the railway from Schenectady to Saratoga, in the State of New York. Parallel trenches are cut 1 ft. 6 in. wide, and filled in with broken stone 1 ft. 6 in. deep, upon which are laid longitudinal timber sleepers B, 5 by 8, with transverse bearers or ties C, 6 by 6, placed 3 ft. apart from centre to centre: on the top are caulked down continuous plates D of timber 6 in. square, with a wrought-iron rail or list on the inner edge, ½ in. thick and 2½ wide, weighing 12·60 lbs. per yard; the ends of the rails are jointed or halved one into the other; the stone sleepers and timber are bedded in broken stones and earth.

Fig. 16.

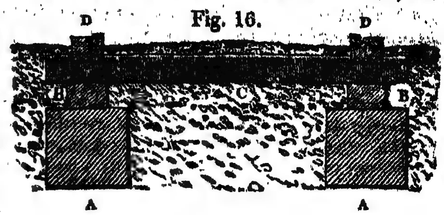

Fig. 17 is a section of the Columbian railway: parallel trenches A are cut 2 ft. 6 in. wide, and 1 ft. 8 in. deep below the surface of the ground, and filled in with broken stone, in which are bedded granite sleepers B, 1 ft. 8 in. square and 1 ft. thick, placed 3 and 4 ft. apart, and connected by transverse iron bars C. The rails D are drawn to a larger scale in fig. 18, 2 in. wide on the top, 3½ deep, and weighing 40 lbs. per yard; they are fixed in cast-iron chairs, weighing 13 lbs., with 2 wrought-iron wedges or keys, weighing 9 oz.: the chairs are fixed to the stone blocks with two wrought-iron pins, weighing 9 oz. each, and 5½ in. long.

Fig. 17.

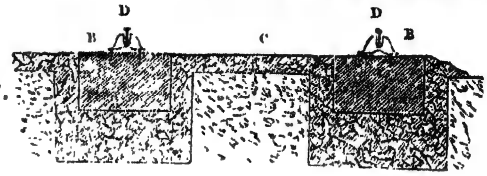

Fig. 18.

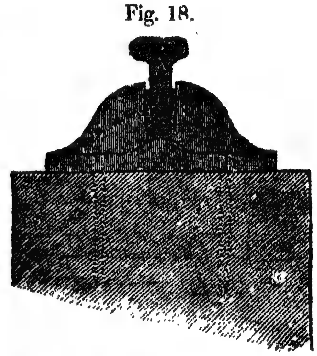

Fig. 19 is a section of the railway adopted on part of the same line.

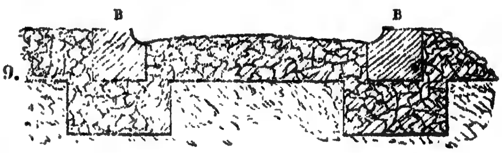
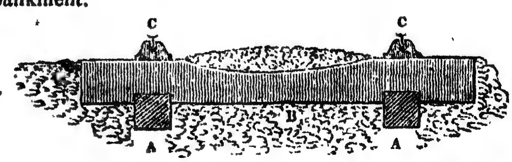
Fig. 19.



Parallel trenches A, are excavated, 1 ft. 10 in. wide, and 1 ft. deep below the surface of the ground, and filled in with broken stones, upon which are bedded continuous stone blocks B, 1 ft. square, hollowed on the edge to allow the working of the wheels; the surface of the road is covered with broken stones.

Fig. 20 is a section of another portion of the railway constructed on an embankment.

Fig. 20.



Longitudinal sleepers A, of timber 8 in. square, are bedded in the earth, on which are notched down transverse bearers B, 7 ft. long, and 9 in. high, hollowed out in the centre for the roadway, upon which are placed the rails and chairs C, similar to those in fig. 18. As soon as the embankments are consolidated, stone sleepers are to be substituted for the timber.

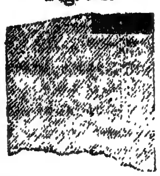
Fig. 21 is a section of the railway from Philipsburgh to Juniata.

Fig. 21.

Parallel trenches are cut and filled in with broken flints, upon which

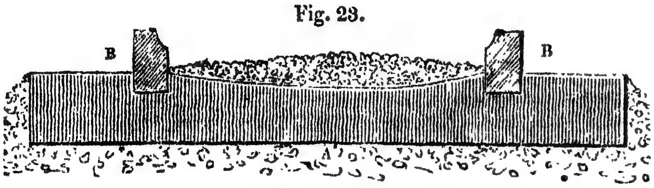
are bedded trees A of white oak, 30 inches diameter, with the under side squared equal to 9 inches in width; on the top are laid transverse bearers or ties B, 8 feet long, 9 inches high, and 5 inches wide, placed 4 feet apart; on the top are caulked down the plates C, of white oak or heart of pine, 9 by 5; the rails, fig. 22, are of wrought-iron bar, 2 inches wide, and half inch thick, weighing 10 lbs. per yard; they are fastened by 5 inch spikes; under the ends of the rails are placed pieces of plate-iron 4 inches square, and a crevice is left to allow the water to pass off the road.

Fig. 22.



For the railway from Charleston to Augusta, they have adopted different modes of construction. Fig. 23 is a section of the railway on clay and gravelly soil; transverse sleepers A, 9 feet long, 10 inches

Fig. 23.



thick, and 1 foot high, are laid 6 ft. 6 in. apart from centre to centre, upon which are caulked down plates B, 6 by 9.

Fig. 24 is a section of the railway on embankments: longitudinal sleepers A, 9 inches square, are laid parallel and continuous, upon which transverse bearers and plates are laid like those in the last figure.

Fig. 24.

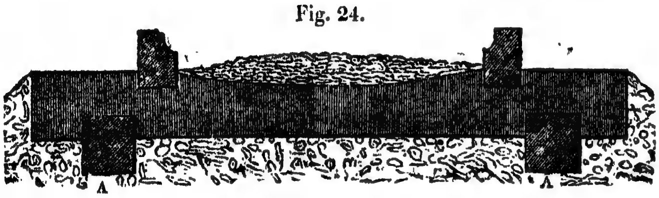


Fig 25 is a third mode of construction, adopted on marshy soils: a scaffolding of timber is constructed with piles A, from 10 to 15 inches diameter, driven into the ground at intervals of 6 feet 6 inches longitudinally, and 6 feet apart transversely: in some soils that offer little resistance, the piles are driven to the depth of 25 feet by a ram, weighing from $5\frac{1}{2}$ to 9 cwt., from a determined height, depending on the resistance of the ground; the driving is continued until the last blow or fall of the ram, from a height of 20 feet, drives the pile less than 2 inches at each fall; in general, holes are made in the ground 3 feet 6 inches deep for the piles before they commence driving: the piles are not pointed, consequently they offer greater resistance, and insure greater stability; after they are properly fixed, they are cut off to a level, and on the top are framed transverse bearers B, 9 feet long, and 9 inches square, upon which are laid the plates C as before.

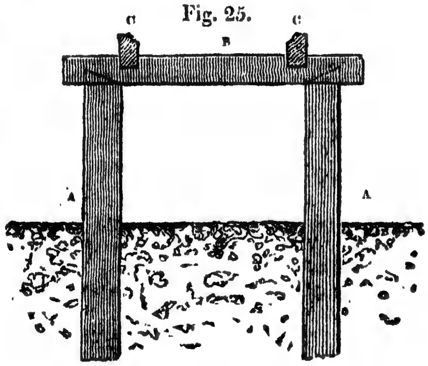
Fig. 25.



Figs. 26 and 27 are sections of the plates and rails: the plates are 6 by 10, and never less than 20 feet long; the edge of the plate is hollowed nearly an inch in depth, to allow for the play of the wheels, and the iron rail projects a trifle over the edge. The rails, fig. 26, are $2\frac{1}{2}$ wide and one inch thick on the inner edge, and $\frac{3}{4}$ of an inch on the back edge. The rails are not fixed until the surface of the plates is made perfectly uniform, so as not to

Fig. 26.

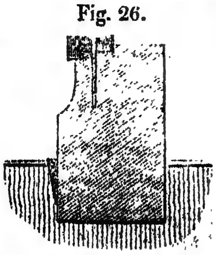


Fig. 27.

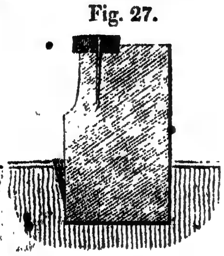

admit the slightest play on the rails. In some situations, where the height of the scaffolding was 15 feet above the ground, they had recourse to struts or braces D, fig. 28, projecting at the base 8 feet, and secured at the foot by stakes E. If the height did not exceed 7 to 10 feet above the natural soil, the struts were not used, but a brace 4 by 5 was introduced between the piles, as D, fig. 29. If the height was above 10 feet from the natural soil, two cross braces were introduced, as D, fig. 30.

Fig. 28.

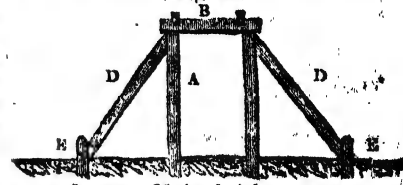

Fig. 29.

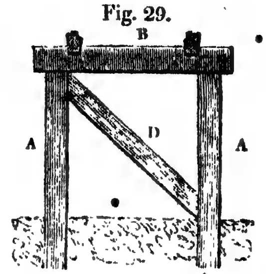

Fig. 30.

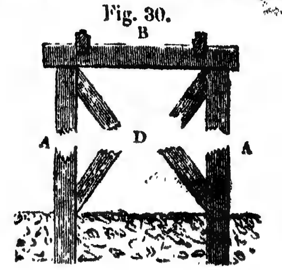
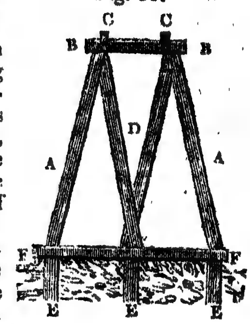


And if the soil was not firm, and the railway was 12 feet high above the ground, a stage was erected with three vertical pieces of timber, as E, fig. 31, connected at the top and bottom by a cross tie F of timber, one foot square, the whole imbedded in an embankment formed of the soil well mixed with sand: on the top of this stage is erected a scaffolding 18 feet high, the shape of the letter W reversed, with timber supports A, and braces D, 10 by 8, framed into the bottom tie F, and connected at the top by the transverse bearer B, 6 feet long, 12 by 10, on which are laid the plates C and rails. This method of construction has succeeded very well.

Fig. 31.



When the elevation is from 18 to 20 feet above the natural soil, pillars or piles are planted, connected at the top by a cross tie one foot square, upon which is erected a scaffolding at intervals of 10 feet, similar to that just described.

REVIEWS.

A Practical Treatise on Calcareous Mortars and Cements. By L. T. VICAT. *Translated, with Additions, by* Captain J. T. SMITH, *Madras Engineers, F.R.S., &c.* London; John Weale, 1837.

THERE are very few works connected with building that enter into a geological, chemical, and practical description of materials, although so very essential to a proper understanding of the qualities of the component parts: to enable us to judge of their applicability to the purposes intended, it would be highly beneficial to the profession if the Institute of Civil Engineers or Architects would offer prizes of adequate remuneration to induce professors of the first ability to write one or more essays on geology and chemistry connected with building materials.

The work before us partakes of the above requisites: the original text is well known to many of the profession as being a most valuable work, but there has been a difficulty in understanding many parts, in consequence of the local and technical terms made use of by the author. The translator appears to have combated with these difficulties, and made himself completely master of them; he has very ably done his duty, not only in the translation, but also in his valuable additions. The work commences with a mineralogical description of the various limestones:—

Calcareous minerals are substances essentially composed of lime and carbonic acid;* they always dissolve, either wholly or in part, in weak acids, with a more or less brisk effervescence, and may be scratched with an iron point.

Limestones are sometimes pure, that is to say, wholly composed of lime and carbonic acid; at others, the lime is associated in intimate combination with silica, alumina,† magnesia, with quartz in grains, oxide of iron, man-

* Carbonic acid is a gas composed of one equivalent of carbon and two of oxygen: it is transparent and colourless, and incapable of supporting combustion or respiration; it combines with the alkalies, oxides, &c., forming the class of *carbonates*.—TR.

† Alumina, or oxide of aluminum as it is now termed, is the substance which forms the basis of the plastic clays.—TR.

ganese,* bitumen, or sulphuretted hydrogen.† The presence of these substances one by one, or two and two, or three and three, &c., constitutes the various kinds of limestone, which are further subdivided into different varieties.

Mineralogists distinguish the argillaceous, magnesian, sandy (arénacés), ferruginous, manganesian, bituminous, fetid, &c.; and then in each of these kinds point out varieties of form and structure, which they specify under the denominations of foliated, lamellar, saccharoidal,‡ granular, compact, globular, coarse, chalky, pulverulent, pseudo-morphous,§ concretionary, nodular (geodiques‖), incrusting, &c., &c.

It is useful to be acquainted with this nomenclature; but that which it is of the most importance for the builder to be aware of, is, that each variety of limestone furnishes a peculiar kind of lime, distinct in colour, weight, in its avidity for water, and above all by the hardness it acquires on being mixed intimately after slaking with the earthy substances known under the names of sand, pouzzolana, &c.

The work then proceeds with an analysis and explanation of several experiments, to decide upon what class the limestones belong to, and the component parts of the several kinds:—

1st. As furnishing the rich limes: 1st, the pure limestones, or such as contain only an admixture of from .01 to .06 of silica, alumina, magnesia, iron, &c., taken separately, or two and two, three and three, &c.; 2ndly, the simple, bituminous, or fetid limestones.

2nd. Such as form the poor limes: 1st, limestones associated with silica in the state of sand, magnesia, the oxides of iron and manganese, in variable proportions, but limited to .15 to .30 of the whole, whether these principles exhibit themselves one by one, two and two, three and three, or all together.

3rd. As furnishing the slightly hydraulic limes: the limestones united with clay, magnesia, iron, and manganese, the relative proportions of which being variable, but not exceeding .08 to .12 of the whole. The oxides of iron and manganese also, being present either in the relations one to one, two and two, three and three, &c., &c., or even entirely wanting.

4th. The ingredients constituting the hydraulic limes. These are the limestones containing silica, alumina, magnesia, iron, and manganese, in variable relative proportions, amounting to not more than from fifteen to eighteen hundredths of the whole, and in other respects such, that the silica always has a predominance, no matter whether the other substances appear, as one to one, or two and two, &c., &c. The iron, manganese, and magnesia, may also be entirely wanting.

5th. The minerals affording the eminently hydraulic limes are, the limestones which contain silica, alumina, magnesia, iron, and manganese, in different relative proportions, but usually limited to from twenty to twenty-five hundredths of the whole; the silica always predominating, sometimes to the extent of forming of itself more than half the whole; and the other substances only occurring one by one, two and two, or three and three, &c. It is very seldom that we meet with them all at one time. The magnesia, and still more, the manganese, are very frequently absent.

The process of burning limestone, and the construction of the various limekilns in use, are next explained, with drawings. The subject of artificial hydraulic limes is fully considered, a proper understanding of which is so very essential to the builder of bridges or waterworks.

The artificial hydraulic limes are prepared by two methods. the most perfect, but also the most expensive, consists in mixing with rich lime slaked in any way a certain proportion of clay, and calcining the mixture; this is termed artificial lime *twice kilned*.

By the second process, we substitute for the lime any very soft calcareous substance (such, for example, as chalk, or the tufas), which is easy to bruise and reduce to a paste with water. From this a great saving is derived, but at the same time an artificial lime perhaps of not quite so excellent a quality as by the first process, in consequence of the rather less perfect amalgamation of the mixture. In fact, it is impossible, by mere mechanical agency, to reduce calcareous substances to the same degree of fineness as slaked lime. Nevertheless, this second process is the more generally followed, and the results to which it leads become more and more satisfactory.

We see that by being able to regulate the proportions, we can also give to the factitious lime whatever degree of energy we please, and cause it at pleasure to equal or surpass the natural hydraulic limes.

* We usually take twenty parts of dry clay, to eighty parts of very rich lime, or to one hundred and forty of carbonate of lime.¶ But if the lime or its carbonate should already be at all mixed (with clay, Tr.) in the natural state then fifteen parts of clay will be sufficient. Moreover, it is proper to determine the proportions for every locality. In fact, all clays do not resemble one another to such an extent as to admit of their being considered as identical: the finest and softest are the best. * * *

Quick-lime, taken as it leaves the kiln, and thrown into a proper quantity of water, splits with noise, puffs up, produces a large disengagement of hot slightly-caustic vapour, and falls into a thick paste: in this state it is termed slaked lime. * * * * * *

This method is generally adopted, but they abuse it strangely. They reduce the lime to a milky consistency in a separate basin, whence it runs off into a large trench. Thus drowned, it loses the greater part of its binding qualities. * * * * * *

All lime, when first slaked by immersion, and then exposed to the contact of the air in a sheltered situation, becomes gradually loaded with carbonic acid and water, but only up to a certain point: the amount of this change, as well as the time required for it, varies with the quality of the lime. * * *

Numerous preliminary trials have shown, that the quantity of water employed in slaking lime exerts a powerful influence on the hardness of the hydrate which results. And this is easily understood. Too little water fails to bind the mass; an excess swells out the stuff, which remains light, porous and friable, if it does not shrink proportionably in drying. Plaster* mixed thin, or stiff, exhibits a remarkable instance of this fact.

The pasty consistency which produces the greatest hardness, is at once ductile and firm. We have given it the name of "clayey," because, in fact we can compare it to nothing better than clay which is in a state of readiness for the manufacture of pottery. It is this kind of consistency which we constantly gave to the pastes of the hydrates made use of in our experiments.

The author classifies the several kinds of mortars under four heads:—1st, "*very energetic*" mortars, which set after immersion within the third day, and acquire the hardness of a brick at the end of one year 2nd, "*energetic*" mortars, which set between the fourth and eighth day after immersion, and at the end of the year acquire the hardness of soft stone; 3rd, "*feebly energetic*" mortars, which set from the tenth to the twentieth day after immersion, and at the end of a year acquire the hardness of dry soap; 4th, "*inert*" rich limes in paste, the presence of which makes no alteration whatever in the manner in which the lime would behave if immersed without mixture. Having established these definitions, the author proceeds to give the result of various experiments, and explain the manufacture of artificial pouzzolanas.

The first and best method consists in previously pulverizing the clay, the psammite, or the arene, which we have selected, and then strewing a layer of it, about a centimetre (four-tenths of an inch nearly) or more, on a plate of iron heated to a point between a cherry red and forging heat. We leave it there till it be raised to the same degree, for a space of time which varies, for each kind of material, from five to twenty-five minutes. We take care to stir the powder continually with a small rod, in order that the whole of the particles may be uniformly calcined. The clays or ochrey psammites, of brown, or orange red, or a full blood red, require a heat of a higher degree and sustained for a longer time, than the others. Twenty minutes, and an incandescence nearer the forging temperature than a cherry red heat, appear to be the limits proper for them. * * *

The second method consists in rendering the material exceedingly porous and permeable to the air, if it be not so already, and then roasting it in the manner of bricks, but in the highest part of a limekiln, where the heat is insufficient not merely to vitrify, but even to give a fusible brick the degree of burning necessary for commerce.

We make the material porous, by kneading it with an equal quantity of quartzose sand, after which it is divided into loaves or prisms, which are left to dry and harden properly. This plan is particularly suited to the compact and fusible clays; but the pouzzolana which results from it has the defect of being mixed with sand; an inconvenience which might perhaps be avoided, by substituting for the quartzose sand any combustible substances in a finely divided state, such as sawdust, chopped straw, wheat-chaff, &c., &c. * * *

All clay, principally composed of silica and alumina, and moreover, fine, soft to the touch, and which contains more or less of the oxide of iron, with little or none of the carbonate of lime, will give a "very energetic" pouzzolana if it be treated by one of the two first methods described above. * * *

---

* Manganese is a metal similar in appearance to iron, but rarely met with in the metallic state.—Tr.

† Sulphuretted hydrogen is a compound gas, containing one equivalent of sulphur, and one of hydrogen. It is liable to be extricated on the decomposition of a metallic sulphuret by water, whence it is not an uncommon natural product.—Tr.

‡ The whitest and most esteemed (granular limestone), from its resemblance to sugar, has been termed by the French mineralogists chaux carbonatée saccharoide; but it has more generally, from its important uses in the arts, obtained the name of *Statuary Marble.—Phillip's Mineralogy*, edit. 1816.

§ Minerals exhibiting impressions of the forms peculiar to the crystals of other substances, are said to be pseudo-morphous.—*Ibid*, p. 1.

‖ A geode is a hollow ball. At Oberstein, in Saxony, are found hollow balls of agate lined with crystals of quartz or amethyst, which are termed geodes.—*Ibid*, p. xlvi.

¶ The 80 parts of lime here mentioned, refer to the lime in the unslaked condition, and the 140 parts to the uncalcined mineral. If the lime be slaked, the proportion should be increased to 110 parts. The mixture here described, is such as to produce the hydraulic limes, whose properties are similar to the Aberthaw, the analysis of which, by Mr. Phillips (Annals Phil., new series, vol. viii., p. 72), shows it to correspond nearly with the proportions here recommended; as it consists of 86.2 of carbonate of lime to 11.2 clay (with 2.6 water and carbonaceous matter), being at the rate of 18.2 parts clay to 140 of the carbonate of lime. The cements now commonly in use in England are much quicker setting than these, and differ from them in being *unslaked*. They contain a greater proportion of clay, but may be manufactured artificially with equal ease, by combining such relative quantities of chalk, or lime, and clay, as will suit the purpose intended. Parker's Patent Cement, as analysed by Sir Humphry Davy (Ure's Dictionary, art. Cement), contains 45 per cent. of clay to 55 carbonate of lime. The Yorkshire cement, 34 clay to 62 carbonate of lime. The Sheppy, 32 clay to 66 carbonate of lime. And the Harwich, which is a quicker-setting cement, 47 clay to 49 carbonate of lime (Practical Remarks on Cements, p. 32.) These facts may serve as a guide towards the admixture of ingredients, for the formation of a compound suited to our purpose, in any situation; but for the exact proportions, recourse must be had to experiment in *every case* when new materials are to be employed. In fact, so different may be the chemical properties of apparently similar materials, that no results however definite, or however successful in one locality, can with safety be trusted to in another, as more than a clew for the direction of similar experiments, applied to the new materials at our disposal. For such trials, the process of manufacture and the choice of clay, &c., are explained in the text; and it is therefore merely necessary to add, that when aiming at the production of a compound similar to Roman Cement, it would be necessary to increase the dose of clay to about that indicated by the composition of the materials from which our cements are manufactured, and in which it varies, as above shown, from one-third to one-half of the whole. Particular attention should be paid to the perfect amalgamation of the materials; and the degree of calcination just suited to it should be carefully observed, before attempting to imitate the process on the large scale.—Tr.

* Plaster of Paris is here meant.—Tr.

The translator adds :—

Two varieties tried by myself, and calcined according to the first method, afforded excellent artificial pouzzolanas. One of them, a stiff brown clay, which did not effervesce in nitric acid, and which turned brick-red after calcination, set in three hours with half its weight of rich lime. The other, a white kind of pipe-clay, in which silica predominated, but containing no carbonate of lime, and which changed to a light pink colour after burning, set in six hours when made into a stiff paste with lime in the same proportions. After five and a half months' immersion, no impression whatever could be made upon the first of these cements, by the action of an instrument exactly similar to M. Vicat's (described at the end of the volume, and represented in Plate II.): upon the second, a very slight indentation was made by the needle, measuring, as nearly as could be ascertained, 0.0125 of an inch.—Tr.

The manufacture of mortars is too frequently left to the sole control of the bricklayer's labourer, without any guide or rule; to obtain a good and lasting mortar requires particular care in the proper mixture of the ingredients, that the lime may be perfectly incorporated with the sand or other substances, and that every particle of these may be surrounded with a coat of lime.

In whatsoever way it may have been slaked, lime ought to be first brought to the condition of a thoroughly homogeneous paste, and then to be mixed with the ingredients destined for it.

This paste ought to be as stiff as possible, whenever it is intended to act the part of a matrix amongst hard and palpable grains, which preserve a sensible interval between one another. Such is the case with mortars, or mixtures of lime and sand.

It may have a more or less thin consistency, when, with a pulverulent substance, whose grains are impalpable, and at the same time absorbent, we would form a whole of a homogeneous appearance, in which the eye is unable to discern any one of the constituent elements. This is the case with the calcareous cements, or the mixtures of lime with the pouzzolanas, arenes, clays, or psammites.

But in every possible case, the resulting mixture, be it mortar or cement, must exhibit a good clayey consistency, according to the definitions laid down in that respect. * * * * *

Mortar in every season ought to be prepared as much as possible under cover, whether it be to avoid the rapid desiccation which takes place in summer, or to obviate the still more serious inconvenience in the rainy season. In the latter case, we ought to deviate a little from the principles which we have laid down in the preceding pages, and choose the hydraulic lime slaked by immersion, in preference to that produced by the ordinary mode; and this in order to have it in our power at pleasure to absorb the water contained in the wet sand; without this plan, it is impossible to obtain a stiff mortar.

In summer, on the contrary, the lime in paste is not always sufficient to moisten the sand, which is sometimes hot. It then becomes indispensable to add water, but gradually, and with the greatest caution. One could hardly believe, without witnessing it, how very small a quantity is sufficient to drown the mixture.

It is quite evident, that a very stiff mortar cannot be used with dry and absorbent materials. When we have materials of this kind, they must be watered without ceasing, and kept in a perfect and permanent state of imbibition. The whole secret of good manipulation and right employ, is condensed in the following precept: '*Stiff mortar, and materials soaked.*' Our bricklayers, on the contrary, seem to have taken for their motto, '*Dry bricks, and drowned mortar.*' * * * * * *

In general, all mortars become pulverulent when, after being applied, they are exposed to a rapid desiccation. The influence of such a desiccation becomes the more fatal, the more eminently hydraulic the mortars are. They may then lose four-fifths of the strength which they would have acquired by drying slowly. It is therefore proper to water the masonry when we build during the hot season; and this in such a way, as never to permit the mortar to whiten, and thus part with the water necessary for its solidification.

On the Continent they appear to have a mixture for foundations similar to our concrete; it is called "*beton.*" It is made by mixing lime as a matrix with stones, fragments, and rubbish: in the work before us, there is no satisfactory account of the increase and decrease of the materials in bulk, after the *beton* is made up. In this country we find among builders very considerable differences on the mixture and proportions of the ingredients of concrete, and also the amount of its decrease. Mr. Godwin, in his excellent treatise, states, "that the ingredients, when mixed, lose one-fifth of the bulk before mixed." We have consulted several eminent builders on the subject, and none allow in their calculations anything like such a decrease: one builder who has made numerous experiments on mortars and concrete, states, that he never allows in his calculations for a greater decrease than from one-fourteenth to one-sixteenth; another builder, who is also performing some large works where concrete is being used in considerable quantities, states that the decrease is about a seventh, and from calculations he showed us, we are disposed to think that his opinion is correct: these differences show how necessary it is for several trials and experiments to be made on a large scale; the differences may very likely be owing to the various qualities of the limes, and the proportion of sand mixed with the ballast. We intend to make every inquiry on the subject, and have now an opportunity of trying on a large scale the actual decrease, and also the expansion after it has set in the foundation, which we shall take an early occasion to lay before our readers. It appears that the translator of the work before us agrees with Mr. Godwin.

For foundations and works of that kind, the use of *concrete* as a substratum in dangerous soils seems in England to be fast superseding every other method, and it offers so valuable a resource in so many difficult situations, that I cannot omit the opportunity of doing the reader a service, by giving a short account of its nature and preparation. Concrete is a composition of stone or rubble and sand with fresh-burned *stone* lime (ground to powder without slaking), in the proportions of from one-fifth to one-ninth of lime, to one of the mixture of rubble and sand. These ingredients should be well blended together *dry*, and as small a quantity of water added as will bring them to the consistency of mortar, and then, after turning over the materials with the shovel once or twice, thrown as quickly as possible into the foundation, from a height of eight or ten feet. It sets very quickly so that it is desirable that the mixture should be made at, or close to the height from which it is precipitated, and after being expeditiously spread and brought to a level, or puddled, it ought not to be again touched. The best proportions of admixture of the stones and gravel or sand, are such as produce the greatest possible condensation, and depend therefore upon the dimensions of both; and the principles by which these proportions may be determined with accuracy, will be found in a note in p. 87, it being remembered that the greater the condensation, or the greater the real bulk of the materials packed into a given space, the *less* the quantity of cementing matter necessary to bind them together. The concrete used near London is composed of Thames ballast, containing about two of stones to one of sand, which proportion Mr. Godwin, the author of a valuable essay on this composition, considers to be the best; and as the size of all the stones used is limited to the bigness of a hen's egg (all beyond that dimension being broken), it will be seen that this practical result is in perfect accordance with the experiments referred to in the note above quoted. The quantity of lime (if *hot* from the kiln, and perfectly well burnt and pulverized) should be such as is sufficient to form good mortar with the *sand* (only), which is the simplest rule to go by, as by it the exact proportions in every case can be decided according to the nature of the materials, and the energy of the lime used, according to the experience and judgment of the architect who employs them. I have not heard of concrete being employed under water, but when once consolidated, it may be exposed immediately to its action without risk. In setting it expands in the same manner as hydraulic lime, which renders it very valuable in some situations. This increase of dimensions amounts to three-eighths of an inch in a foot in height on the first setting of the concrete, and it continues to expand insensibly for a month or two afterwards. It is proper to add, that this expansion follows a previous condensation of about one-fifth in bulk, by which the ballast and lime are found to be contracted after being incorporated together.—Tr.

We have entered more fully into this work than we at first intended, but the importance of several parts of the work has induced us to make our extracts rather full; we have not been able to touch upon the valuable information and tables contained in the Appendix, but we must conclude by recommending the work itself to the attentive perusal of the Profession.

Papers on Subjects connected with the Duties of the Corps of Royal Engineers.

The excellent example of the Institute of Civil Engineers, in publishing the first volume of their Transactions, has brought forth similar works from the Architects, and the Corps of Royal Engineers; the latter work is now before us, and contains many very interesting papers, but not to such an extent as we were led to expect, from the well-known abilities of several scientific members of the Corps, which we fear may rather arise from a punctiliousness in appearing before the public, than for the want of talented means. However, we must hope that in their future works there will not be such backwardness; in these times men must not have any narrow views in keeping secret their improvements and inventions; let all scientific men go hand-in-hand in furthering the objects of their profession, and we shall soon have works in this country that will vie with those of the ancients or moderns, no matter in what part of the world.

The first paper is strictly professional, appertaining to the Royal Engineers; it contains a very interesting account of various *Assaults* by Lieutenant-Colonel Reid. The next three papers are on *Concrete*, by Lieutenant Denison: one of them is a description of the construction of a *Bomb Proof*, made with Mr. Ranger's patent concrete, and the particulars of the effects produced by the fire of artillery on the *Concrete experimental Casemate*; it appears that it stood the fire of seven shells and two 24-pounders, which began to operate on the works. The following paper is *A description of the Concrete sea-wall at Brighton, and the Groins which defend the foot of it*, by Lieutenant-Colonel Reid. This paper sets at rest the erroneous opinion formed by many builders, that mortar could not be made with sand from the sea-beach or sea-water, as it would not set: it appears, from the Report before us, that both were used, and with complete success. It is scarcely

known to what extent concrete may be advantageously used; we feel convinced that it might be introduced for every variety of building, and with great economy, particularly near rivers where clean ballast can be obtained, or near gravelly soils (the gravel should be washed, to clean it from alluvial impurities): in such situations concrete might be introduced at one-half the cost of brick, and would have the appearance of stone. Mr. Barry has very successfully introduced it in the new front of the College of Surgeons, Lincoln's-Inn-Fields, also in the front of a house in Pall-mall. Mr. Ranger has built a small church with concrete, also several docks, wharfs, and numerous other works; and has used it in the sea-wall at Brighton, with great success, as appears by the Report before us.

The portion of the concrete sea-wall now constructing at Brighton is 3,000 feet in length: and this portion, together with what is already finished, will make a length of about 2,000 yards of wall, the whole constructed of the sand and shingle from the beach alone, cemented by a water-lime from the neighbourhood, and mixed up with salt-water, the water having been taken from the sea itself, until it was found more convenient to sink wells immediately at the back of the wall, where some fresh water becomes mixed with the salt.

The section of the wall is two feet and a half thick at the top, upright at the back, without counterforts, and battering in the front with a slope equal to one-third of the height. The foundation goes down to the chalk, and from the bottom to the top, it will in one part be seventy feet high: in many, forty feet.

The lime is not ground, but slaked at the work, as it is going to be used, and first mixed by hand with three parts of sand. It is next wheeled to a plug-mill, and then intimately mixed with three parts more of shingle, after which it is wheeled away and thrown upon the wall. In its semi-fluid state, it is retained by boards ledged together. The wall being backed up as it proceeds, the rear ledges are easily supported by struts. To retain the front ones in their places, ties are used made of saw-plate iron, in strips passed through the boards, and keyed at the outer end. At the inner end, long iron needles pass through holes in the strips of saw-plate, and pin them to the ground. These needles and strips are easily drawn out, and used again as the work proceeds. The surface sets the second day, and after ten days the ledged boards may be removed. * * *

The lime used in the concrete wall is taken from a pit near Bycombe, eight miles north of Brighton, and is a weak water lime. The lime used for a row of houses now building of concrete, at Brighton, is from the pit of Southerham, near Lewes, and is also a water-lime. According to Mr. Mantell (who has so long studied the geology of the south-east of England), both these pits are in the strata of chalk-marl, lying under the lower chalk formation; and it is to be found at the northern escarpments of the South Downs, and the southern of the North Downs. These two lines are similar to the Dorking and the Halling (near Rochester) limes; and it will be intersting to ascertain, whether all the limes burnt from the same stratum have the same property.

It has been stated above, that the great sea-wall (at least in its new state) cannot resist the beating of the surge against it; and that its security depends upon the system of groins in its front. It is however deserving of remark, that some of the same concrete has been used near low-water mark, to fasten some piles at the lower extremity of one of the groins, which were loosely placed in large holes in the chalk bed of the sea, and into which concrete was poured, in its usual semi-fluid state. The place where it is, is almost always covered by the sea; yet it has become so hard that it resembles rock, and it was not found practicable, on examining it, to detach a single pebble from the mass without procuring iron tools.

Another trial of laying this concrete under sea-water has been successfully made at the outer end of the Brighton chain-pier. Some time back, large artificial stones of concrete made of the Bycombe line were moulded, and after being allowed to harden on shore, they were placed at the feet of the outermost set of piles of the Brighton chain-pier, to aid in securing them. These also have become very hard, and are now encrusted with shell-fish; whilst the chalk thrown in at the same place is soft and pulpy, and evidently wearing by the action of the sea.

These experiments led Mr. Wright, late surveyor to the Brighton Commissioners, and now employed upon the Dover Railway, to propose to construct a substantial groin of concrete, to be coped with stone, and having sides with gradual slopes. The Brighton Commissioners, however, have not authorized this trial to be made, which is to be regretted.

The contract price of the concrete in the great wall is fourteen shillings for each square reduced to fourteen inches thick, the Brighton mode of measuring, which is equal to three shillings and fourpence a cubic yard.

The paper by Lieutenant Luxmore, giving a *Description of the Groins used on the Coast of Sussex for preventing Encroachments by Sea*, is instructive to the Engineer.

A short Description of the Use and Construction of Groins.

A groin is a frame of wood-work, constructed across a beach, between high and low water, perpendicular to the general line of it; either to retain the shingle already accumulated, to recover it when lost, or to accumulate more at any particular point.

The component parts of a groin are piles, planking, land-ties, land-tie bars, blocks, tail-piles and keys, and screw-bolts.

The length of a groin depends on the extent, and the requisite strength of its component parts on the nature, of the beach on which it is to be constructed. Those at Eastbourne, on the coast of Sussex, of which the following is more particularly a description, are from 150 to 250 feet in length; and the beach at that place being very rough, consisting of coarse heavy shingle and large boulders, they require to be composed of proportionably strong materials to resist its force.

The piles are from twelve to twenty-five feet long, and eight by six inches and a half scantling, shod with iron.

The planking is in lengths of eight, twelve, and sixteen feet, two inches and a half thick, and with parallel edges.

The land-ties are of rough timber, from twenty to twenty-five feet long, and large enough at the butt end to receive the bars.

The land-tie bars are thirteen feet six inches long, and twelve by five inches scantling.

The land-tie bar blocks are about two feet long, and of the same scantling as the piles.

The land-tie tail-keys are about two feet six inches long, and six by two inches and a half scantling.

The above materials are of oak or beech.

The screw-bolts are of inch round iron, two feet nine inches and a half, and two feet one inch and a half long, in equal proportions.

The relative proportions of the component parts are, four piles, one land-tie with tail-piles and keys, one land-tie bar with two blocks, two long and two short bolts, about 180 square feet of planking, and about 140 six-inch spikes for every sixteen feet in length; and the expense of a groin, constructed with materials of the above dimensions, may be calculated at about 30*l.* for the same length.

General Rules observed in the Construction.

When the object in constructing a groin is to recover shingle, or accumulate more, the first pile is driven at the high-water mark of neap tides, leaving its top level with that of spring tides. The next is driven at the point on the sands beyond the bottom of the shingle, to which the groin is to extend, leaving about four feet of it out of the beach.

The tops of these two piles may be taken for the general slope of the groin, unless the beach should be very steep, and much curved, in which case it becomes necessary to follow its curvature in some degree.

From the high-water mark of neap tides, the piles are carried back nearly level to that of spring tides, and as much further as may be considered necessary.

The piles are driven four feet asunder from centre to centre, and so as to admit the planking between them alternately; and they should be sunk about two-thirds of their length.

The longest piles, are placed between the high-water mark of neap tides and the bottom of the shingle, particularly from twenty to forty feet below the former point.

The planking is, if possible, carried down to about two-thirds from the tops of the piles, and kept parallel with them.

The land-ties are placed about one-third from the top of the planking, (supposing the latter to commence from the tops of the piles,) and their tails are sunk to the level of the bottom of the planking, or as nearly so as possible.

The method of uniting the component parts of a groin is shown by the accompanying plan, elevation, and section.

The land ties have, in some cases, been placed on either side alternately, in which case one-fourth more land-ties, bars, &c., are required in the construction, because it then becomes necessary for the land-ties to overlap. The principal reason however for giving the preference to placing all the land-ties on the westernmost side is, that when placed alternately, those on the easternmost side are, from the general prevalence of westerly winds, liable to be left wholly exposed; and when in that state for any length of time, they are apt to free themselves from their tail piles, and endanger the safety of the groin.

The planking should only be carried up to about one plank above the land-ties at first, and afterwards gradually completed, as the shingle accumulates, which should pass over it at about high-water, so as to form itself on the same level on both sides at the same time; for when the planking is carried up too high at first, the shingle is removed from the leeward side, by the general motion of its surface, in the direction in which the sea is running, before it has accumulated high enough on the windward side to pass over and supply the deficiency; so that when it does pass over, the reaction of the sea on the leeward side produced by the then difference of level, prevents it from settling there. Before this error was discovered, it frequently happened, when the wind continued in the same quarter for any length of time, that the planking became exposed to the very bottom on the leeward side, the shingle accumulated on the windward side passed under it, and the groin becoming undermined was soon destroyed.

When a set of groins are constructed, they are placed from fifty to one hundred feet or more apart, according to their length.

The six papers by Mr. Howlett are particularly interesting to the profession. The first, *For determining altitudes with the Mountain Barometer*; the second, *A new method of making perspective drawings from plans and dimensions*, which is very simple and easily acquired. The next paper explains a *Field Protractor and Sketch Book*, useful in making a sketch of a country on a small scale, by taking the distance by stepping, allowing 2 feet 6 inches to each step, or 40 steps for 100 feet, and the angles by a small pocket surveying compass, and laying down the lines and angles in the Sketch Book as you proceed.

The following paper describes a very simple *Substitute for a drawing-board*, which is frequently required in a country survey; a good straight edge or flat ruler is fixed on the top of a table near the edge with a pair of small clamps, and against the ruler is worked the back edge of a T square, the stock being flush with the blade on the under side. Mr. Howlett's new *Station Pointer* is very useful; so, also, is his *New Line-divider and universal Scale*, of which the following description is given.

This simple instrument is for dividing a given space into any number of parts, and for drawing parallel lines to any scale with a common drawing pen, more accurately, and in most cases more expeditiously, than can be done by the ruler and compasses.

The next paper is on the *Construction of the Rideau Canal*, by Lieutenant Frome, which fully describes the whole of the works, their construction and estimate; and contains a variety of information useful to the Engineer.

There is a paper by Lieut.-Colonel Reid, giving *A short account of the failure of part of the Brighton Chain Pier in the Gale 30th November*, 1836. If we could always be furnished with accounts of failures in engineering works, it would tend more to correct errors and mistaken notions than many years of arduous labour and research.

The paper by Capt. Savage, giving *A description of the Landing Wharf erected at Hobbs' Point, Milford Haven*, contains full particulars and drawings of the four diving-bells employed on the works, together with a description of the machinery for working them, and of the mode of executing the works under water; the whole highly instructive, particularly to those who have under-water works to execute: we are satisfied that such works, in many instances, might be executed by diving-bells, which would save the enormous cost of coffer-dams, steam-engines, pumps, &c. The repairs and removal of the damaged stone at the foundations of the piers of Westminster Bridge were entirely done with the diving-bell; and the construction of the Lara Bridge is another instance, where the whole of the piers were built under water in a rapid stream by means of a wooden diving-bell, constructed by Mr. Rendell the Engineer. There are several other works in this country which have been executed, at a comparatively small expense, by the use of the bell.

A report on copper pontoons, by Colonel Pasley, forms the subject of the next paper, wherein he recommends the Neapolitan pontoons.

The 18th paper is *An investigation of the position of the horizontal axis of a self-acting sluice gate*, extracted from an article in the "Memorial du Génie." The author has entered into an algebraical calculation to find the equation of equilibrium for sluice gates.

The concluding paper is a report on *Mr. Kyan's process for the preservation of timber from dry-rot*. We shall, at present, refrain from making any remarks on this paper, as we are endeavouring to make ourselves masters of the subject by acquiring all the information we possibly can obtain as to the *infallibility* of the remedy, before we presume to give an opinion upon the subject.

An Appeal to the Public on the Subject of Railways. By George Godwin, Junr., *Associate of the Institute of British Architects.*

This Pamphlet contains many convincing arguments showing the advantages of Railway communication; we recommend the enemies of Railways, and several of the fastidious members of the House of Commons, to read this brief appeal, in the hope that it will make them converts.

A Tabular Chronological Epitome of the History of Architecture in England. By George Godwin, Junr., *Architect.*

This Epitome is printed on a card, and shows at one view an approximation to the date, duration, and characteristics of the principal styles which have prevailed in some examples, with names of the Architects. A few similar Epitomes on Architecture would be an excellent appendage to the Architect's office: by suspending them in the waiting-lobbies, the impatient moments of parties might be instructively occupied.

Original Geometrical Illustrations. By John Bennett, *Engineer.*

This work contains a great variety of geometrical figures, ingeniously and simply divided into equal and proportional parts: their simplicity caused us to doubt whether we had not seen some of the illustrations in other works, but on referring to several, we could not find them. The author, however, does not attempt to give a mathematical demonstration to prove their correctness, nor does he show in all cases how the operation of sub-dividing is to be performed; he appears to consider that the whole is so self-evident, that any one can understand them. This we readily admit; and for general purposes, and for most men who are not fond of Algebraic formulæ, a practical work of this kind is quite sufficient. We cannot very well enter into an explanation of the work without illustrating our review with copies of the engravings; probably we may allude to it again in a future Number.

Temples, Ancient and Modern; or, Notes on Church Architecture. By William Bardwell, *Architect.* London: James Fraser and John Williams.

We received this work just as we were going to press, and have not had an opportunity of taking more than a cursory glance;—it is beautifully got up—the engravings and wood-cuts are executed in a masterly manner. The text appears to be written with great judgment and research; in our next Number we shall enter more fully into this work.

A Review of the Professional Life of Sir John Soane, *with some Remarks on his Genius and Productions; read at the Institute of British Architects. By* Thomas Leverton Donaldson, *Fellow and Honorary Secretary, &c.* London: John Williams.

A faithful Review, written in a concise and classical style.

The following Works were received too late for review, and will be noticed in the next Number.

Prolusiones Architectonicæ, or Essays on Subjects connected with Grecian and Roman Architecture. By Wm. Wilkins, R.A.

Appendix to Elements of Architectural Criticism. By Joseph Gwilt, Architect.

Thoughts on the Experience of a better System of Control and Supervision over Buildings erected at the Public Expense, and on the Subject of Rebuilding the Houses of Parliament. By Lieut.-Colonel the Hon. Sir Edward Cust.

Treatise on Drawing Instruments. By F. W. Simms, C.E.

Preparing for Publication.

Before our next Number is out, we expect two very important Works will be published connected with the Profession.

The Public Works of Great Britain, containing 130 folio plates, beautifully engraved, copied from the Original Drawings.

Railway Practice, containing copies of the Drawings and Specifications of several important Railways.

COHESIVE STRENGTH OF BAR IRON.

The mean result of numerous experiments on wrought-iron, detailed in the *Journal of the Franklin Institute*, made by a Committee of the Institute at the request of the Treasury Department of the United States.

	Specific gravity.	No. of Experiments.	Strength* in lbs.
Missouri Bar Iron	7·7708	22	47909
Ditto Slit Rods	....	2	50000
Tennessee Bar	7·8046	21	52099
Salisbury, Connecticut	....	40	58009
Swedish Bar	7·4785	2	58184
Centre County, Pennsylvania	....	15	58400
Lancaster County, Do.	7·7400	2	58661
English 'EV best patent Cable bolt Iron'	7·6897	5	59105
Do. Do. hammer hardened	7·6897(!)	8	71000
Russian Bar	7·8014	5	76069
Phillipsburgh Wire, diam. .333	....	13	84186
Phillipsburgh Wire, diam. ·190	....	5	73888
Phillipsburgh Wire, diam. ·156	....	5	89162
Cast Steel	....	1	130681

The experiments were made at ordinary temperatures on bars of Iron, averaging ¾ inch by ¼ inch.

* Breaking weight of an inch square bar, deducting friction.

LAW PROCEEDINGS.

SECONDARIES COURT, *Sept. 2nd.*

THE BIRMINGHAM, BRISTOL, AND THAMES JUNCTION RAILWAY COMPANY, *v.* LEWIS.

This was an action brought by the Company against the defendant, who is a proprietor of twenty-five shares, to recover the amount of the calls made by the directors, and interest thereon.—The secretary proved the defendant to be a proprietor of twenty-five shares, and that there was a call of 2*l.* per share due in October last, and another of 1*l.* subsequently, and produced the act of parliament, giving power to the directors to sue and to recover the amount of any calls duly made, with interest thereon until paid up.—The jury found for the plaintiffs, damages 75*l.*, and interest.

Warwick Vase.—There can be no doubt that immense treasures are still buried under the ruins of Alexandria, but whether they will ever be discovered, will depend upon the pacha's necessities, as he may need the ruins of ancient temples for building forts, or bridges. New discoveries are constantly made, and between my first and second visit a beautiful vase had been discovered, pronounced to be the original of the celebrated Warwick Vase found at Adrian's villa, near Tivoli. It was then in the hands of the French consul, who told me he would not take its weight in gold for it. I have since seen the vase at Warwick Castle; and if the one found at Alexandria is not the original, it is certainly remarkable that two sculptors, one in Egypt and the other in Italy, conceived and fashioned two separate works of art so exactly resembling each other.—*Extract from "Incidents of Travel in Egypt, &c., by an American."*

ADDRESS.

A Journal intimately connected with the Profession is generally admitted to be much wanted—whether we have adopted the right course to meet the exigency, will be for their consideration. We are now before them on our trial, if we have failed, it is not for want of exertion; we have started the work, we may safely say, in the very worst season, when there is not a Scientific Institution open that is connected with either Profession, and scarcely any information to be obtained, excepting through our own personal exertions; neither have we yet been able to complete our Foreign Correspondence and arrangements for obtaining whatever useful information can be collected on the Continent and in America; this we hope will be completed ere our next Number appears—but we trust allowances will be made. Our pages will be open to all, no matter from what quarter information or communication may come; if it be deserving of consideration or merit, it will receive an insertion in our Journal;—we are independent of all parties—no interest or affection have we for one more than another. "Open to all, but influenced by none"—it is our desire to be the organ of the Profession, to communicate what is moving, and to watch over any abuse or infringement upon the practice of either: we solicit all parties in any way connected to render us their assistance; let the Journal be considered as their own; recollect that by mutual information much may be obtained. Every professional man must be doing or seeing something new, let him take a note of it and forward it to us; it is impossible for us to be able to collect what is going forward in all parts of the Kingdom, nor can our work become interesting or useful, without such assistance; therefore, if you wish to have a Journal devoted to your service, you must give it support by contributions. To our Professional Friends who are abroad do we also appeal; if we contribute to them what is going forward in England, let us ask in return for such information as may be connected with the Profession in the quarter of the globe where they are residing or travelling. Nor let it be considered, because our Journal is published at such a trifle as *Sixpence* per Month, that it will be undeserving of notice; look to our pages, and it will be found that our humble Journal contains as much matter as is to be found in many octavo and quarto volumes that are published at twenty times the price: it will be our anxious duty and study to devote our energies to the service of the Profession, which we hope will be crowned with success, and their approbation.

PROSPECTUS.

The object of this Publication (which will be continued monthly) is to afford a medium of communication to all parties interested in either of the above Professions.

It will contain Descriptive Particulars of Important Buildings, Manufactories, Warehouses, Railways, Docks, Bridges, Piers, Harbours, Canals, Rivers, Water-works, Gas-works, Drainage, Mining, Steam Navigation and Machinery, illustrated with Engravings, Estimates, Specifications and Calculations.

It will also contain a Monthly Record and Transactions of English and Foreign Societies, New Inventions, Patents, and Public Improvements—Reviews and Notices of Books as they are published—Reports of Parliamentary Proceedings, Engineering Evidence, Standing Orders—Law Reports and Decisions; and such other useful information connected with the Profession as may make it a Work of general reference.

The Editor will be happy to receive any Communication or Drawings from the Profession and others. Particular care will be taken of such Drawings or Papers as may be intrusted to him, and they will be returned when requested.

Advertisements for Contracts, Competition Drawings; of Public Meetings, Societies, Books, New Inventions, or any other subject connected with Engineering or Architecture, will be inserted.

Communications to be addressed "To the Editor of the Civil Engineer and Architect's Journal," *at the Office, No. 57, King-street, Westminster, where all Advertisements and Books for review are to be sent.*

ORIGINAL PAPERS AND COMMUNICATIONS.

NEW STANDING ORDERS.

We cannot too early call the attention of the Profession to the New Standing Orders of the *late* House of Commons—we never witnessed any proceeding in the House that was anything like the indecent manner in which they were introduced, at a time when there was not a tithe of the members in town, and they that remained were fully engaged in securing their own seats for the future Parliament. A copy of the Orders was delivered to the members in the morning of nearly the last day of the session, and on *the same day* they were moved and carried, without allowing a single day for the members to pause and consider them, although urgently requested, neither giving the public the least notice of what they were likely to be;—we believe that the like cannot be found on the records of the House. —Orders acting retrospectively were unheard of before;—the promoters have carried their point for the present, but we trust that some spirited member will move, when they are *proposed to be adopted for the new Parliament, their rejection or amendment.* Not the slightest regard was paid to the new orders of the House of Lords, nor any consultation with their Lordships on the most obnoxious clauses;—no, the promoters of the new Orders set aside every form—every respect that was due, both to the House of Lords and the public, fearing the rejection of their clauses. If it were their wish to check the further progress of railways, why did they not do it manfully,—and bring forward a definite motion to that effect, instead of putting a stop to them by a side-wind? This sneaking kind of legislation must be put an end to; we were much surprised that the press allowed them to pass so quietly: the whole proceedings of the late House of Commons during the past session, relative to railway bills, were most unprecedented—it appeared as if certain members were strongly connected with the solicitors in putting the companies to every expense that was possible. What a farce was carried on before the Deptford and Dover Committee! Three of the Brighton Railway Companies (one of them fighting for delay) were before this Committee at one time, where all laws of evidence were totally disregarded; worthless witnesses, whose evidence would scarcely have been heard in a court of justice, were encouraged to calumnize whomsoever they pleased. The circumstances of those who had been unfortunate many years back, but were now doing well, were exposed before this Committee, simply because they had subscribed for a few shares, and their names appeared on the railway subscription deed;—not satisfied with this, the Committee must publish their names in the halfpenny sheet libels of the House. Witnesses were compelled to criminate themselves before this Star Chamber inquisition!—So disgusted were counsel engaged before this Committee, that after having made several unsuccessful attempts to check the inquisitorial proceedings, they abandoned all further resistance, and allowed the farcical proceedings to go on unchecked.

We have no complaints to make against the Standing Orders of the House of Lords, they are framed in the best spirit; instead of increasing the severity of their Orders, the House has relaxed them; formerly they required five-sixths of the capital to be subscribed, now they only require three-fourths.

We will now proceed to point out the variance between the Standing Orders of the two Houses of Parliament:—first, with regard to the plans, the Commons have, against the evidence of a most respectable engineer examined on the subject (we suppose for nothing), introduced an order that the section of the railway shall be marked on the line of the railway laid down on the plans, which we are satisfied to the uninitiated will make the plan still more complex and confused; the fewer lines there are on the plans the better are they understood.

The Lords require that the notices shall be published (excepting notices that have been given agreeable to the *then* Standing Orders) in the Gazette and Newspapers, in the months of October and November, and the plans, &c., deposited on or before the 30th day of November, and that no subscription list shall be valid unless it be proved, that previous to the introduction of the bill into the House, five per cent. upon the amount of each share subscribed for has been paid, and has been expended, or remains applicable to the purposes of the railway, at the discretion of the directors of the proposed company.

The Commons require the notices (excepting renewals of application) to be published in February and March, and the plans, sections, &c., deposited on or before the first day of March; and that it be proved that a sum equal to one-tenth part of the amount subscribed be paid up and deposited in the Bank of England or Scotland, or invested in some Government security in the name of the Clerk of the House of Commons for the time being, and of any two persons named by the promoters of the bill, the said sum or securities so to remain until the bill has either passed or been rejected by the House, or been withdrawn by the parties, &c.

A CURSORY GLANCE AT THE PRESENT STATE OF ARCHITECTURE IN ENGLAND,

CHIEFLY WITH RESPECT TO THE METROPOLIS.

Not very long ago Mr. Welby Pugin thought fit to bring out, under the title of 'Contrasts,' a most extraordinary volume, the object of which was to decry all his professional brethren—at least, all those to whose works he referred,—and to represent architecture as at the very lowest ebb in this country. Since then he has attempted to defend it in two seperate pamphlets, one entitled a "Reply to observations which appeared in Fraser's Magazine for March, 1837, on a work entitled 'Contrasts;'" the other, "An Apology for a work entitled 'Contrasts,' being a defence of the assertions advanced in that publication against the various attacks lately made upon it;" for although he had run quite a-muck at every one else, Mr. Pugin is exceedingly thin-skinned and sensitive himself, and notwithstanding that he had satirized—we may say, vilified the whole profession, and even caricatured the styles of some of the most eminent in it, he has no relish either for *Fraserian* quiz, or more serious reproof. With that modesty which always accompanies real genius, he is fain to believe that he is a much injured, and greatly misrepresented person; and in order to vindicate his pretensions to candour, fairness, and liberality, he pours forth in his so-called "Apology" a torrent of rabid gall, against the Protestant Church and every thing connected with it, not forgetting sectarians, and those "canting fanatics," Quakers; besides lavishing abundance of vituperation on architects and artists of every other description among us, more especially engravers and printsellers, whom he accuses of corrupting the public taste, and in some degree public morals likewise. In short, he vents himself upon every person and every thing in such a *Furioso* mood, that it is to be regretted his baptismal name is not Orlando.

It is not our intention to pursue Mr. Pugin any further—at least, not on the present occasion; we shall not therefore, among other puzzling questions that might be put to him, ask him to explain how it has happened, that—notwithstanding Roman Catholicism, both its forms and creeds, are so highly conducive to art, so potent to create and foster genius,—all the fine arts are at this moment nearly paralyzed in Italy? and that Portugal, one of the most bigotted countries, presents little better than a dreary blank in regard to painting and the sister arts; whereas, according to his notable theory, that land should have been fertile of great artists beyond almost every other! The influence attributed by him to the Popish Church exclusively must sometimes, it would seem, be inoperative—absolutely inert. But we turn aside at once from such questions, and from Mr. Pugin, to whom we have called attention merely as the fierce promulgator of opinions most offensive, and couched in the most intemperate and insolent tone—besides being indefensible in themselves, and contradicted by facts.

In order to show how ill-founded and full of sophistry is the course adopted by that redoubtable gentleman, for the purpose of making it appear that architecture is at present in the most deplorable condition among us, we need only observe, that he has been compelled to have recourse to the doubly disingenuous expedient of bringing forward some of the most paltry erections, or else the most egregious failures, he could ransack up, and invidiously to contrast such abortions with some of the finest examples of earlier periods; and also of suppressing what is creditable to contemporary talent, and to our own times. Such being the case, we cannot perhaps do better than here exhibit to our readers a *contrast* of a very different kind. We will therefore take a hasty glance at—we ought perhaps to say enumerate, the principal structures that have been erected in the metropolis alone within about thirty years, that is during the regency and the two last reigns. In that comparatively very brief space of time, more has been done than during the whole of the preceding century; and many of the buildings erected of late years must be allowed, by every competent and unprejudiced judge, to be greatly superior to anything of the same class belonging to the immediately preceding period. Now, whatever the *candid* Mr. Pugin may think—and for candour he takes very great credit to himself in his book—we hold this to be an equally fair and rational mode of ascertaining whether we are actually advancing or retrograding, instead of making such preposterous comparisons as he has chosen to do;—a method, by-the-by, both invidious and discouraging, and one the *animus* of which cannot be mistaken, the censure being totally unqualified. Neither is it admitted, even in general terms, that if we are still greatly behind our ancestors, in many respects, we are at least very much superior to our immediate predecessors.

We are, we hope, ourselves quite as ardent though less bigotted admirers of our ancient English architecture as the "Preterpluperfect Goth;" nor do we pretend that modern times have as yet produced even a single edifice that will stand the test of comparison with York Cathedral, King's College Chapel at Cambridge, and other masterpieces of that kind. But then we have produced structures, even in the Gothic and Tudor styles, that may fairly be pronounced of first-rate merit when *contrasted* with the pitiful attempts of the last century. We need only mention the Hall at Christ's Hospital Newgate-street, the Free Grammar School at Birmingham, and Cossey Hall in Norfolk. That this last-mentioned edifice should not have been in any way alluded to by Mr. Pugin, is indeed surprising, since it belongs to a Roman Catholic family; but, it seems, neither his remarkable candour nor his flaming Catholicism could prevail upon him to quote even a single example tending in any degree to invalidate his general proposition: not so much as an exception was to be admitted. Well! the 'candour' of some persons is absolutely incomprehensible!

It must, indeed, be admitted, that we no longer build pompous cathedrals, or lordly abbeys and castles, and that for one very plain reason—because we have no occasion for them. But we do erect numerous structures of various other kinds, some few of which may be pronounced even magnificent, and many exceedingly elegant and beautiful: they are moreover for the greater part, such as our ancestors were either totally unacquainted with, or bestowed little architectural finish upon. Foremost among them we may place our metropolitan bridges, not to mention many other public works of a similar class in different parts of the kingdom, which, for magnitude of undertaking, and boldness of conception and execution, are difficult to be paralleled. On the other hand, the generality of our modern churches are, with one or two striking exceptions, rather poor and inconsistent in their architecture; which last-mentioned defect is in a great measure to be ascribed to our endeavouring to adhere to models intended for the Romish service and its ceremonies, instead of boldly setting them aside altogether, and allowing free scope both to our ingenuity and our taste in devising such arrangements and embellishments as would be more suitable for a modern Protestant Church; whereas at present we suffer ourselves to be checked by precedents which we dare not entirely abandon, yet to which we cannot conform with much propriety or success.

With the exception, however, of that single class of buildings, which certainly does justify some reproach, nearly all the rest show that architecture has made a very rapid stride among us since the commencement of the present century. This, like all similar propositions, is of course to be understood *cum grano salis*; for we do not mean to assert either that there is not a single building of the preceding period that is not quite eclipsed by those which have been since erected; or that every thing erected within the last thirty or thirty-seven years manifests a decided improvement. On the contrary, there are many positively bad, or, if not altogether bad, very inferior; and be it observed, it is such as these which the *candour* of Mr. Pugin has ingeniously singled out and thrust forward as specimens of the architectural talent of his contemporaries. Nevertheless, so far from being at all disheartened by such display, we have reason to congratulate ourselves when we find that it consists of no more than what we can very well afford to give up to scorn and derision, it being the mere husks and chaff, and not our actual harvest. Considering that architectural design has of late years increased about a hundred-fold—we do not think we at all exaggerate the matter—and that it is now aimed at in buildings where formerly nothing whatever of the kind was attempted, but which would have exhibited no other front than a naked wall, pierced with openings for the windows; it is not by any means surprising that we should so frequently meet with instances of exceedingly bad taste, of common-place vulgar decoration, of impotent attempts at design: yet even all this, contemptible as it undoubtedly is in itself, is, if occasionally disgusting, upon the whole less wearisome than the insipid blankness and monotony to which we formerly condemned ourselves.

While we freely admit that we cannot boast of much that has been done in the way of Church architecture, we may very well refer with some feeling of pride to other public buildings and works, and to the very great improvement which has taken place in Street architecture generally. Neither has the attention which has of late years been paid to architectural design been confined to the metropolis, but it has displayed itself more or less in all our principal provincial cities and towns; for instances of which we need only to name Liverpool, Birmingham, and Newcastle. And when we consider the very great variety of the buildings themselves, we must allow that architectural talent has a much more extensive field opened to it than formerly, since our Club-houses, Literary Institutions, Insurance Offices, and other buildings of that description, constitute almost entirely new classes of public edifices, while among them will certainly be found some of the most ornamental façades which now grace our streets. Besides them we have now spacious covered markets, some of which possess considerable architectural character, although it is not of that kind which arises from decoration. 'Arcades,' as they are termed, and Bazaars, form likewise another new feature in the London of the nineteenth century; and if we no longer rear such religious structures as those our ancestors have left to us, we do build, in addition to those just alluded to, public Museums, Libraries, Schools, &c., which are in accordance with the spirit of the present age, and bear honourable testimony to the spread of information among all classes. Still all this, it may be said, amounts to little more than a vague, rhapsodical declamation: well then, let us now come to particulars, which we will do by enumerating some edifices that have either been rebuilt, or erected in lieu of older ones that occupied other sites. We ask those, therefore, who remember the former buildings, whether the present Bank of England, Goldsmiths' Hall, Fishmongers' Hall, the Post Office, St. Paul's School, Corn Exchange, St. Dunstan's-in-the-West, College of Surgeons, Hall of Christ Church Hospital, St. George's Hospital, &c., exhibit so decided a falling off from the edifices they have taken place of, as justly to fill us with shame and regret! For Mr. Pugin, indeed, we will not answer, but we may venture to answer for every one else—"most assuredly not." Or should there be any one so perverse as to maintain the contrary, and assert that architecture has sadly degenerated among us, instead of other argument, we should simply refer him to two very sufficient examples of the taste of their respective periods; and if, after studying them both, our opponent should declare Temple Bar to be a much more noble and elegant piece of architecture than the Arch at the corner of Grosvenor-place, we should not attempt to reason him out of his fancy.

We ourselves have given it as our opinion, that the majority of the new churches have very little architectural merit,—are decidedly inferior to most of the other buildings of the same date; still there are one or two marked exceptions. That of St. Dunstan's-in-the-West has already been named by us, and we now add those of St. Pancras, St. Mark's North Audley-street, and Hanover Chapel Regent-street, as deserving to be ranked among the most classical pieces of architecture in the metropolis.

In regard to the New Palace, that indeed we abandon without compunction to general and unmitigated reprobation, as a most miserable work, stamped throughout by insignificance and meanness, without one single merit of any kind—any one single quality—any individual beauty, capable in the least degree of redeeming its effects and deficiencies. With the National Gallery it is somewhat otherwise, because although we are compelled to acknowledge that it has fallen greatly short of our expectation, that it is in many respects very poor and undignified, and very unsatisfactory, when taken as a whole, still it does possess one fine feature, namely—the portico; not that even this is perfectly unexceptionable, there being an air of nakedness and poverty about the entablature and pediment. Nevertheless, when viewed at such distance that the eye takes in no more than the portico, and some of the parts immediately adjoining it, it forms a noble object, and is attended with an effect very different from that of any other piece of architecture of the kind in the metropolis. We are further of opinion, that although much dissatisfaction with the National Gallery has been pretty generally expressed, it is partly owing to our having become somewhat fastidious; for the time was, and that no very distant one, when the same design would have stamped the fame of its author, and have been hailed as a splendid pile of architecture. At all events it is an acquisition, which is more than can be said of the Palace, since that has not even the merit of at all improving the site it occupies, or being a nobler object than was Buckingham House.

We have mentioned several buildings which, being only substitutions for older ones, do not increase numerically our former architectural stock; we will now catalogue such metropolitan structures as are entirely new, and which will be found to furnish a tolerably long list, although we include in it only such subjects as are of some note. To begin with those miscellaneous ones which do not admit of being classed along with others of the same kind respectively, we have the Colosseum—a building that would at one time have been regarded as a sort of prodigy, the London University, the Pantheon Bazaar, the York Column, the State Paper Office, Richmond-terrace, the new buildings at the British Museum, Exeter Hall, the Gateway into Hyde-park, and the Arch opposite to it at the corner of Grosvenor-place, the Lowther Arcade, and that on the west side of the Opera-house. Among the Club-houses, which considered with reference to architecture may be said to form an entirely new class of buildings,—we have the Union, the University, the Athenæum, the Travellers', the Conservative, and the Oxford and Cambridge (not yet completed); to which may be added the Law Institution. Under the head of schools, may be mentioned, King's College, St. Olave's School, the City of London School, and that for the indigent Blind—unless this last mentioned is rather to be considered an eleemosynary asylum, than a place of education. In the way of addition to our hospitals, we have now the Charing Cross and Westminster Hospitals; among literary institutions, the only one at present of any great architectural pretension is the London, in Finsbury Circus. Insurance-offices have given much more employment to the profession; and among them we may notice the Atlas, the British, the County, the Law Life, the Legal and General (now building), the Globe (do.), and the Marine (do.). We might without difficulty very greatly extend this list; and in fact, we ought not to pass over in entire silence the very tasteful little building in Ebury street, which was till lately the Pimlico Grammar school; but we would rather lay ourselves open to the charge of omitting some things we might have named, than of inserting whatever we could muster up, in order to make as great a display as possible. Nay, we do not pretend to affirm, that all the buildings we *have* specified are of first rate merit; on the contrary, we freely acknowledge, that several of them required to be looked at with a somewhat indulgent eye, their chief merit consisting in their being embellishments to their respective sites. It is enough for our present argument, that compared with an equal number erected in the last century, the superiority will be found to be greatly on their side. And if of so many buildings that have risen up almost simultaneously, even no more than a minority will satisfy the fastidious critic, we may be tolerably content with what has been done, and look forward without despair at the future.

ON THE SELECTION OF THE CLASSICAL STYLE OF ARCHITECTURE FOR BUILDINGS OF NATIONAL IMPORTANCE, AND THE VARYING OF THE CHARACTER OF SUCH BUILDINGS SO AS TO MARK THEIR DESTINATION AND USE.

By A. W. Hakewill, Esq., Architect,

Member of the Architectural Society of London.

Of all the arts the pursuit of which tends to promote the comfort and dignity of a nation, that of Architecture is the most conspicuous; and progressing as it does in intimate connexion with the other arts of civilization, it may be considered as affording a fair criterion of the wealth, capacity, and taste of a people. Architecture affects more or less all ranks of the community, from the highest to the humblest individual in the state,—the taste of all is influenced by the spirit manifested in buildings; the physical and moral comfort of all are improved by a skilful disposition of plan, and suitable choice of architectural detail. The welfare of such an art must then appear to be of vital importance, and hence the necessity of conducting it upon correct principles.

The object proposed in this paper, is the consideration of Architecture as a fine art, and as having thereby a tendency to strengthen the moral influence of a nation, by exalting the character of its institutions, and shedding grace and dignity over the land.

Taking this view of the art of building, the propriety of selecting the most beautiful style for national purposes will be readily conceded. Fortunately for the result of this question, the truly beautiful in art is not an arbitrary affair, which must necessarily vary in character with every change of society, amenable to no laws but those of fashion; but certain and defined, based upon principles at once eternal, and of the most exalted character, those exhibited in the human form.

The scope of fine art is to affect the mind strongly and lastingly, with a view to raise in it admiration for the nobler virtues: the human form is the element with which it works to effect this lofty purpose; no other object in nature would so immediately conduce to it; for setting aside all consideration of the quick sympathy excited in us by the contemplation of our own species, it is of all others the most winning upon the mind, from the combination it presents of the highest sentiment with the most graceful flow of line—the union of the utmost moral and physical beauty.

The full power of the human form was keenly appreciated by the Greeks, who were thereby induced to seize every occasion of displaying it in connexion with their architecture. Art as treated by the Greeks,—let us not call it Greek art, for their style, the most refined, may be equally that of all nations, based as it is upon principles unchanged and unchangeable;—art thus treated, that is, rendered independent of local circumstances, such as climate, laws, and customs, becomes by the intelligible character which it thus acquires, comprehensible to all, equally expressive in all times and places, and so extends its sphere of utility, acquiring thereby the title of *liberal;* thus widely differing from local art, which, indifferent to the portrayal of sentiment and passion, aims at the mere representation of the reigning fashions, displays man their victim, and so renders him an enigma in the eyes of posterity.

The remains of Greek sculpture afford a striking exemplification of the enlightened mode of treating art: in the Parthenaic frieze, for instance, the sculptor, penetrating into the philosophy of his pursuit, which consists not in servilely representing a scene, but in presenting to the beholder objects of high interest, has given us the *beau ideal* of the human race, and by gracefully casting aside the garments, has, in thus yielding to nature her rights, blended truth with his subject, and so invested it with real dignity.

It is owing to the ample instruction afforded through the medium of the classic style of art, that the remains of Greek and Roman antiquity are treasured up by nations, whilst those of the middle ages and other epochs find favour only here and there in the eyes of lovers of curiosities.

Architecture, to possess true sublimity of character, should combine with painting and sculpture, and to form an harmonious union with those arts, must derive its origin from the principles upon which those arts are based; and since the study of the human form constitutes the essence of painting and sculpture, so must it in some way necessarily form the basis of the beautiful in architecture. Such a system as that sought for, have we received at the hands of the Greeks, a nation chosen it would seem to direct our mental vision towards the sublime, in all those arts, the pursuit of which so exalts and dignifies the social state.

In investigating the system of architecture practised by the Greeks, we trace its origin to the study of the human form; for whilst we perceive that the mouldings, those parts that give life and movement to a building, are composed of lines analogous to those that bound the human body, we are made sensible that the contemplation of no other object in nature could have built up in the mind so exquisite a system of proportions as that manifested in the three Greek orders of architecture. Their aspect fills the mind with delight; they exhibit no exaggerated quality, but rather rivet attention by the display of a well-poised combination of many excellences, all tending, under the guidance of marked propriety of thought, to the realization of grace and dignity.

So beautiful are the details and proportions of the orders, and so complete are they in every respect, that a conscientious study of them forces upon us the conviction, that architecture with the Greeks, far from being the primitive art, was on the contrary the last production of the mind—of the mind enriched with notions of *the beautiful*, imbibed through a zealous devotion to the study of the human figure, and ardent research into the truths of geometry; for if we consider it otherwise, and that architecture took the lead in the progress of Greek civilization, we are left in the dark as to the source of its impressive beauty; but viewing it, as it has been already remarked, as *the result* of mental refinement, we can account for the beauty and accuracy of thought displayed in the orders, which we hail as the legitimate and graceful offspring of art and science.

The enlightened thought manifested in the architecture of the Greeks has won for it the appellation of classic, in contradistinction to other styles, in relation to which it may be said to stand as does man to the rest of the animal creation, for in Greek architecture we have the manifestation of the beautiful, the *beau ideal* in the art of building; the result of the most refined and exalted taste, the classic style is alone applicable to the lofty purposes of art, and is invariably found to be chosen for such occasions by civilized nations, whenever public opinion upon the subject is allowed sway.

The classic style recommends itself moreover, through its great susceptibility of modification, a quality essential in the architecture of a nation actively engaged in developing their mental resources. Beauty and invention, the scope of classic architecture, its natural tendency is to advance. Unfettered by the consideration of dates, epochs, fashions, and peculiarities connected with a limited state of civilization, he who cultivates the beautiful style finds it ever fruitful with resources at the juncture of novel circumstances, and ready to unveil new features as necessity demands. Unlike other styles which constantly refer the artist to some remote and obscure period, keeping his attention *chained* to that which is already invented, the classic style by affording through its free unshackled nature the amplest facility for the illustration of mental improvement, prompts invention and bids man progress;

therefore is it selected by nations seeking honour in the career of architecture as their only efficient weapon in the intellectual contest. As an instance of the resources of the beautiful style of architecture, the modern cupola may be cited, of which England possesses so admirable a specimen.

The next care, after selecting a style of architecture for buildings of national importance, is so to vary it as to impress each building with an appropriate character. Character is the soul of art, and the necessity of making a particular study of it in architecture will be apparent on considering the nature of the art itself. Architecture is the landscape with which civilized man surrounds himself. When man, abandoning a roaming life, settles in a particular spot and forms therein a community, he bids farewell to numerous beautiful objects of nature, substituting in their stead those of art. With the marked individuality of character as well as variety manifested in the objects of nature, all are struck; it therefore becomes of paramount importance that we should preserve this attribute in the works of our own creation.

Nothing tends more to the proper training of the mind than the contemplation of objects possessing a decided and fit character; he, therefore, who undertakes to design buildings, contracts a heavy responsibility with his fellow-beings, as there are few objects of equal importance which come so frequently under their consideration.

Character in works of art indeed generally presents itself under two points of view—positive character and its gradations. To particularize, a prison will necessarily possess a stern character; but a prison built in an age of barbarism and tyranny, and in which the fine arts have little or no existence, will present a far more forbidding and repulsive aspect than one built under more favourable circumstances, as that of Newgate for instance. To the lasting honour of Dance be it remembered, that he conceived the true character of a prison built in an enlightened and civilized epoch. The subdued severity of the building softens the character of the institution itself, proclaiming it to be maintained for the protection of society, not for the oppression of man: in it we are in no way reminded of a bastile; the science of the architect, the philanthropy of the Christian, go hand in hand in this composition, in which the graceful and severe are happily united; with the dread avenging spirit is blended the god-like characteristic of the merciful, allaying to a great extent the oppression created in every feeling mind by the contemplation of such buildings, and suggesting the probability of a humane treatment of the unfortunate inmates.

For felicity of expression, St. Paul's Cathedral stands unrivalled amongst the buildings of its order: it announces itself as a temple erected to the Divinity by a powerful and enlightened nation; its sacrificial and propitiatory character would seem to manifest the gratitude felt by our ancestors for the many blessings vouchsafed by Providence to the inhabitants of this portion of the globe, and their full sense of the awful responsibility resulting from that sway which it was granted to them to exert amongst the nations of the earth. Composed as this building is, of elements frequently applied prior to its erection, we admire the way in which the artist has escaped from the shackles of precedent; but the grand original conception flows, in this instance, from the only true spring whence man can hope to draw forth thoughts worthy of such great occasions—from a mind impressed with the grandeur of Nature's works, and exulting in the omnipotence of their Author. Of the truth of this we are made sensible, our minds becoming tuned into harmony with these sublime considerations as we gaze upon the building.

In Greenwich Hospital, we behold a building not less celebrated for the character it displays, than for the profound knowledge which it exhibits of the rules of art. It is but a hospital, though possessing a most palace-like appearance; but the English know well how to tolerate in this instance the elevation of style.

The Roman critic, Milizia, says, remarking upon this building, "that the world is at once reconciled to the sumptuosity of this hospital, upon reflecting that it is the asylum of the bravest of the brave—the British mariner; that it is a monument erected by a nation, sensible of what it owes to those who have maintained her triumphant and free." If we are delighted at the magnificence and convenience of this design, we are no less inclined to admire the bias of that mind, which could, whilst creating, pay such deference to accessorial circumstances, and thus appreciate the merits of the surrounding and distant landscape.

Greenwich Hospital is admirably fitted to its position. It would seem, that nature wooing art in this beautiful region, art had unfolded its various powers to pay homage to the loveliness of nature, willing to receive great part of its lustre from so sweet a union. Which of the principles predominates, it is not easy to determine; it is most true that the principle of art forms first of all the chief motive of attraction, but it must be confessed with the apparent intention of directing the vision to the distant upland scenery upon which the eye so luxuriantly reposes. Seated amidst the beauties of nature, Greenwich Hospital seems designed with a view to their embellishment, just as a fair hand or neck receives additional lustre in our eyes through the agency of some graceful ornament.

Happy were it for us as a nation, did our public buildings manifest more frequently than they do, the same intelligent spirit: that we of the present generation may have to applaud similar discrimination and taste in the erection of public buildings now under consideration, must be the ardent wish of every genuine artist and true lover of his country. May it therefore so happen, that those who wielding the destinies of this great empire have its talent at command, may exercise such judgment in directing it, as to preserve for us the character of an enlightened nation, and maintain the national honour. We are the more disposed to lay some stress upon this; for let it not be supposed, as it might be on a prior consideration, that where apt sentiment is not perceived in buildings, the want of it is always to be attributed to the architect; for this to be the case it is essential that those who control him in the first instance, should be penetrated with the true importance and dignity of his art, and the value of the artist's own studies; where this is not the case, the architect will be subjected to ignorant and discouraging interference, precluding all hope of the proper termination of his labours.

Were an instance sought which might stand as an example of misrule in the affairs of architecture, we should cite a building lately erected, still known by the appellation of the "National Gallery," which fails to possess real fitness of character in the same ratio as the above-mentioned buildings abound in it.

The dignity of the art itself, the importance of the subject, the value of the architect's own studies, have all been lost sight of in this instance. Had the importance of the subject been duly appreciated, a less inconvenient spot could have been selected for the erection of the building; in the present instance an excessively narrow piece of ground has been allotted to a building the destination of which precluded great altitude. This latter disadvantage might have been combated had the architect been able to make a receding front, with a court faced towards Charing Cross by a screen; the play of outline, the variety of light and shade, would then have contributed their share to grandeur of effect, to say nothing of the greater convenience resulting from such a disposition. But the architect has been prevented adopting this plan by the existence of buildings in the rear of his own, such as the barracks and workhouse, and of great importance too it would seem in the eyes of his controllers. Of so much importance were they deemed, that the architect was actually crippled in his design for a "National Gallery," by the necessity of providing additional entrances for the use of those buildings: whence he has been compelled to cut gangways through the façade on either side the portico, thus destroying that repose and severity of outline which, in an architectural point of view, formed the only resource left him by the unaccommodating nature of the ground.

Moreover, for a sum inadequate to the purposes of a "National Gallery," the architect has been compelled to unite with it the distribution and requisites of an Academy of Arts; and the lamentable parsimony manifested in this undertaking has been carried to the extent of suggesting the wretched expedient of introducing features of a demolished building, which, having been scraped and made to look new, their true proportions altered, have been, in defiance of all principles of harmony, and deference to the architect's own conceptions, forced into the design. No money has been allowed for sculpture of an appropriate character, which would have given expression to the building; and so little understanding of the nature of architectural embellishments has been manifested, that with a view to trick up the building, and make it effective at a cheap rate, ornaments ready at hand and of a character however irrelevant to the subject were made use of in the first instance, and the good sense of the public was for awhile outraged by the absurd spectacle of a monument to the peaceful arts bearing on its front works commemorative of war and strife.

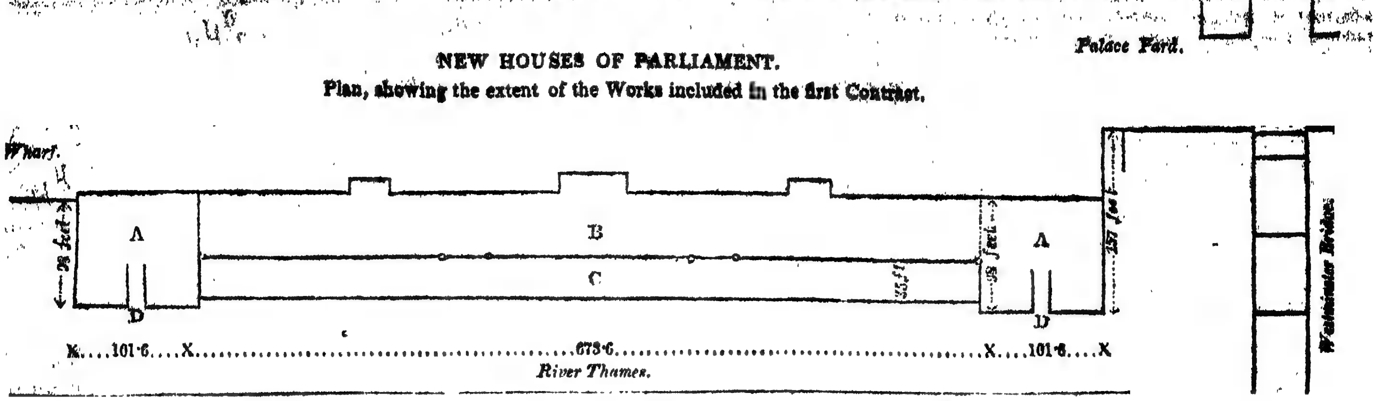
When we consider the source whence this building springs, from a nation ranking amongst the wealthiest and most powerful upon the face of the earth; and the object to which it is destined, one of the most exalted and beneficial to society that man in all the extension of his mental powers can uphold—the fostering and promoting the polite arts, which he recurs to at the cessation of anarchy, darkness, and brute force, as to the highest privileges of his mind;—when we view the "National Gallery" in connexion with these thoughts, its insignificant appearance becomes in the last degree humiliating to our national feeling; we feel that by it the arts are dishonoured, that the term national is burlesqued.

All that can be urged in favour of the building is, that though devoid of character, and wofully bald, it is not altogether destitute of grace; that what ornament it possesses is well executed, and that it displays the elements of taste in a sufficient degree to authorize the belief, that the artists engaged upon it would have produced grandeur, had they been but fairly treated: this it appears to us is the utmost favour that the most candid criticism can extend to the subject.

The ample means however of consolation afforded to us by numerous private buildings lately erected in London, prevent our lamenting long over this unfortunate affair. To a few of these we now beg attention, imagining their merits to be of that high order which should secure for the art itself the solicitude and generous encouragement of those whose exalted stations in the service of their country give them presidency over its various sources of honour and commercial profit:—First, then, that masterpiece of architectural composition, which shines so brightly by night as well as day, Hanover Chapel in Regent-street, in which beauty and convenience are united, and a sacred character preserved; the graceful portico and atrium of the Chapel in North Audley-street; the Travellers' Club, Pall-mall, in which the playful and the severe of the Italian style are happily elucidated; much of the lately erected interior of the College of Surgeons; the Bank of England, a building teeming with beauties of the highest order. It will scarcely, we think, be denied, that these buildings prove that the admirable feeling for architecture which displayed itself two centuries since, still exists amongst us; and that, with the co-operation of the Legislature, as circumstances occur to bring this feeling into play, there can be little fear of England's derogating from that high position in the art which her former brilliant achievements in this field of intellectual exertion have won for her, with the consent of all civilized nations.

NEW HOUSES OF PARLIAMENT.

Plan, showing the extent of the Works included in the first Contract.



A Esplanade B Site of New Building A Esplanade
D Stairs C Terrace D Stairs

The first contract for the commencement of the works was entered into at the beginning of last month: the works are to be executed under the joint direction of Messrs. Walker and Burgess, Civil Engineers, and Charles Barry, Esq., Architect. Messrs. Lee are the contractors; amount of tender reported at 73,335*l*. The works to be done under this contract are most important in regard to construction; they comprehend the formation of an embankment 876 feet in length, projecting into the river 98 feet beyond the present embankment; the front will be in a line with the inner side of the third pier of Westminster Bridge, in four feet of water at low tide: the whole to be surrounded by a river wall, 30 feet high from the base, and 1,141 feet in length, with a curvilineal batter, and faced with granite. A terrace 673 feet long next the river, and 35 feet wide, is to be formed in the front of the new Houses, with an esplanade at each end 100 feet square, and landing-stairs from the river 12 feet wide. The foundation wall of the front of the new building, the length of the terrace, and 30 feet high, is included in the contract; also the whole surface of the front building, which is to be excavated and filled in with concrete 12 feet thick, forming a permanent and solid foundation for the superstructure. A coffer-dam is to be made surrounding the works, 1,236 feet long and 10 feet wide, before they can be commenced.

The following are the particulars of the construction:—The *coffer-dam* is to be first made by dredging a trench in the bed of the river, in the form of a segment of a circle, 27 feet wide, and 8 feet deep in the centre, which is done to allow of the piles being driven the more easily; two parallel rows of guide or main piles of whole timbers will then be driven at five feet apart, leaving a width of nine feet between them transversely; to these piles will be fixed three tiers of waling of whole timbers, cut down and bolted together, one tier to be fixed at the top on a level with high-water mark, another level with the bed of the river, and the third midway; the piles and waling are then to be bolted across with iron bolts 12 feet long, forming a carcass for the inner or sheet piling; the inner main piles will be firmly braced to resist the thrust and pressure at high-water; the whole of the piles are to be 36 feet long, to be driven through the gravel and two feet into the clay substratum, which is twenty-eight feet below high-water mark: within the waling will be two parallel rows of sheet piling, the outer or river side will be of whole timbers, and the inner or land side of half timbers. After all the piles are driven, the gravel forming the bed of the river between the piles will be excavated down to the clay, and the space between, 34 feet high and 5 feet wide, will be filled in with clay and puddled. There will be fender or guard piles at 10 feet distance from the coffer-dam, with floating booms to prevent craft running against the works. After the coffer-dam is complete, the bed of the river will be excavated the whole length of the river wall, 39 feet wide and 12 feet deep, to form the terrace; the front and inner wall will be 24 ft. 9 in. high, standing on a course of concrete 1 foot thick, upon which will be bedded two courses of 6 inch stone landings; the lower thickness of the wall will be 7ft. 6 in., and the top 5 feet, with counterforts 16 feet apart, 3 ft. 9 in. wide by 3 feet 4 deep; the back of the wall will be carried up perpendicular, and the front will be faced with granite, laid in horizontal courses 2 feet thick, with bondstones 4 feet thick and 6 ft. 6 in. apart; the face of the granite will form a curvilinear batter of 2 ft. 6 in. in 22 feet. At 30 feet distance from the inside of the river wall will be built the front wall of the new building, which is to stand on a foot of concrete, with two courses of 6 inch stone landing; the lower part of the wall will be 6 ft. 4 in. wide, and the top 4 ft. 6, and 24 ft. 9 high. Between this wall and the river wall a space, 30 feet wide, 673 ft. 6 in. long, and 27 feet high, will be filled in solid with concrete to form the terrace; the foot of the river wall will be protected by sheet piling of whole timbers 8 feet long, with a waling along the top bolted with iron bolts, 6 feet long and 4 feet apart, with screws and nuts let into the stone-landings of the footings; the river wall to the front and side of the esplanade will be 1 ft. 2 in., and 2 ft. 3 in., thicker than the terrace wall; and the whole surface of the esplanade will be excavated and filled in with a solid bed of concrete 20 feet thick.

In a future Number we will endeavour to give the principal quantities of the materials, and further particulars.

LONDON WATER COMPANIES.

All the Companies are expending enormous sums of money for improving their supply of water in the metropolis. The *Grand Junction Company* are expending a sum that cannot be far short of £200,000; they are erecting extensive works at the entrance of Brentford, under the direction of —— Anderson, Esq., for the supply of water from the river Thames, on the south side of a small island about 400 yards above Kew Bridge, where there is an excellent stream of pure water. The works commence in the centre of the stream; about 4 feet under low-water mark is an immense cast-iron semi-cylindrical chamber, with a grating to the front 10 ft. 6 in. long, and 3 ft. in. high, flat on the top and under side, which is bedded in the bottom of the river by means of the diving-bell. Branching from and connected with the cylindrical back, is a cast-iron conduit or pipe 3 ft. clear diameter, which is laid horizontally 3 to 4 ft. below low-water-mark, and continued on towards Kew Bridge, turning round the island, and crossing the other arm of the river to the bank on the north side. The first portion of the pipes is laid down by the diving-bell, and the other part by forming a coffer-dam, equal in length to three of the conduit. The joints are very ingeniously and simply executed; the pipes have a spigot and faucet joint: round the outer rim of the spigot is cast a narrow and thin collar, which is turned in a lathe rather conically; so is the interior rim of the faucet; both surfaces being ground perfectly true, they fit into each other, and form a perfectly secure water-joint, without any assistance of packing, lead, or other material; and to prevent the pipes from coming apart, there are two eyes cast on the rim at each end of the pipes, which are connected by means of two nuts and screw-bolts—thus the pipes can be very expeditiously connected under water by means of the diving-bell, or in the coffer-dam. From the banks of the river, the conduit is built in brick and cement, and continued across the wharf and under the road to the opposite side, where it terminates in a shaft or well: to this point the water flows from the river, as the whole of the conduit is laid horizontally and under low-water mark: connected with the shaft is a four way cast-iron chamber; one of the apertures is closed, the other two, at right angles with the conduit, are furnished with two sluice cocks or valves, 42 inches diameter, which shut off or open a communication with two wells under the engine pumps: here the water is to be pumped up by means of four steam-engines, which are being manufactured by Messrs. Maudslay and Field; their united power will be equal to 500 horses. Two engines only are to be worked at one time, which are to raise the water to supply the Company's reservoirs at Paddington, a distance of six and a half miles: for this purpose it will require 4,000 lengths of cast-iron pipe, in lengths of 8ft. 6in. to 9ft., and 2ft. 6in. clear diameter, of inch metal, weighing from 29 to 30 cwt. each: they are to be connected by spigot and faucet joints run with lead (about 1 cwt. required to each joint); the cost of the pipe, including lead, laying, removal of surplus ground, and making good the roads, is estimated at £8. *per yard*: each pipe is proved by an hydraulic engine before it leaves the wharf, at 160lb. pressure on the square inch, which is equal to 11 atmospheres. The elevation of the reservoirs at Paddington is about 86 feet above the works at Brentford, consequently there will be an hydraulic pressure of about 36lb. per square inch on the pipes at the ford end. At Paddington the water will flow into the Company's r when it will supply, by means of their present engines, the different parts of the Metropolis which is within their division.

The *West Middlesex Water Company* are laying down a conduit similar to that of the Grand Junction Company across the river Thames, from their works at Hammersmith to the opposite side of the river, where they formed reservoirs covering many acres of land for receiving the water the river, and allowing it to deposit any impurities it may contain, and filtering it before it be conveyed into the pipes or conduit across the T

The *Chelsea Waterworks Company* are also about to lay a sim across the river Thames, from their works at Chelsea to the opposite side, where they will form extensive reservoirs in Battersea Fields, House.

sinking a well at the foot of the Hampstead Road to a considerable depth, and of large diameter; the upper part for a few feet is steined in brick set in cement, and the

is formed by cast-iron cylinders, each length gradually diminishing in diameter, so that the under one may pass through the upper one successively, similar to a telescope-tube; the iron cylinders are made perfectly water tight, to prevent the land springs impregnating the water in the well: after sinking the well to a considerable depth, they commence boring, which will be continued until they come to the pure soft spring-water of the chalk stratum, which is supposed to lie about 300 feet below the surface.

The *East London Company* are about to erect a new engine-house, and have one of the Cornish steam-engines, equal in power to all their engines combined.

STEAM NAVIGATION.

We have inspected the new steam-ship fitting out for conveying passengers between London and Hull, named the *William Wilberforce*, lately launched from the building-yard of Messrs. Curling and Young, at Limehouse. We do not remember having seen a finer or more perfectly formed steam-ship afloat; her length over all, exceeds 200 feet, and her extreme breadth athwart the paddle-boxes 46 feet. When we inspected her, the draught of water was only seven feet six inches, but without coals, or water in the boilers.

We were much pleased with her engines, manufactured by Messrs. Hall of Dartford, which are now being fixed on board in the East India Dock: we understand that they are the largest marine engines that have been put on board any vessel in the river Thames, and are only second in size to the engines which are now being manufactured for the new steam-ships building for the American trade; each of the engines of the *William Wilberforce* is of the computed power of 144 horses, having a stroke of six feet, and paddle-wheels 24 feet in diameter, and eight feet six inches wide. The two foundation plates upon which the machinery stands, are each 26 feet long, and 5 feet 9 inches wide, with deep feathers or flanches, and condensing chambers, all cast in one piece, and weighing between 11 and 12 tons. The forged work of the shafts and cranks are excellent, and from their magnitude such as could only have been accomplished by machinery, powerful as that possessed by the house that supplied them, the Messrs. Acraman, of Bristol. The engines are provided with three cylindrical boilers, 25 feet in length, with interior cylindrical tubes or flues, the whole complete weighing between 50 and 60 tons. The chimney is of novel construction, being enclosed in a jacket, forming an air-tight casing throughout its entire height, the space between the funnel and casing serving the twofold purpose of receiving the surplus steam from the safety valves, and thus dispensing with the ordinary waste steam-pipe, and of keeping the interior of the chimney at a high temperature, and thereby increasing the draught through it without that excessive and unsightly enlargement of its dimensions which would have been necessary on the ordinary construction. It also prevents the possibility of the sails or rigging of the vessel coming in contact with the chimney. The total weight of the boilers, engine, water, and compliment of coals for the voyage, is estimated at 310 tons. We should have stated, that the engines, besides being provided with every precautionary contrivance against fire, bursting of boilers and other casualties, are also fitted with Mr. Samuel Hall's (of Basford) patent condensers, which have been in successful operation in the *Hercules* and other steam-ships for nearly two years, and have fully answered the important purpose intended—that of supplying the boilers of marine engines with pure distilled water instead of salt or muddy water, which on the ordinary plan is unavoidable; by which process the internal parts of the engines are not exposed to the corrosive effect of the salt injection water and salt vapour as with the common injection engine, and thus their durability as well as that of the boiler is greatly increased, while a more perfect performance of the engines is obtained with a diminished consumption of fuel.

For a view of the engines, we are indebted to Mr. Francis Humphrys, under whose able direction they have been constructed. Mr. Humphrys also exhibited to us a model of an ingenious invention which he has lately made, for obviating the possibility of marine boilers being deficient of water; or of their injurious expansion by the sudden shutting off the steam from the cylinders, so frequently occurring in navigating the river, or in going in and out of harbours, which causes serious injury to the boilers by straining the rivets, and opening the joints of the plates. The apparatus also renders explosion from under pressure next to impossible; we shall at some other time give a description of this important appendage to steam boilers.

We wish the spirited proprietors of the *William Wilberforce* (the Humber Union Steam Company) the full measure of public support, so justly due to them for their liberal and meritorious efforts in providing this costly example of British skill, which we believe will be found to combine every improvement capable of imparting safety and celerity to the ship, and confidence and comfort to the passengers.

The *Great Western* steam-ship has just come into the East India Dock to have her engines put on board; her build is of beautiful proportions, with a round stern. She was built at Bristol; her tonnage is calculated at 1,300 tons; she is to have two marine engines of 200 horse power each; the cylinders are 73½ inches diameter; and she is to have four boilers. She is intended to trade between London and New York.

The *Victoria* steam-ship, now building by Messrs. Curling and Young, is the largest steam-vessel built in this country, and is intended for the same trade as the *Great Western*; her length on the water-line 230 feet: she draws, when unloaded, 11 feet; when loaded, 15 feet; breadth of beam 40 feet, depth of hold 28 feet; breadth, including paddle-boxes, 69 feet; her tonnage is estimated at 1,800 tons; she is to have two steam engines of 230 horse power each; the cylinders are 78 inches diameter, paddle-wheels 30 feet diameter. Estimated to cost, including her engines, £100,000.

SIGNALS ON RAILWAYS.

Sir,—In consequence of the numerous accidents daily occurring upon railroads, I have considered that they might be in great measure averted by the following plan; possibly some part of the scheme may have been suggested before, but I trust, under the present circumstances, you will consider it worthy of insertion in your Journal.

I propose that a series of masts, 50 or 60 feet high, be erected on the most prominent situations, not exceeding one mile apart, and flags of different colours hoisted to various heights, and worked by the railway police, to notify any communication, stoppages, or accidents, which may be transferred from one part of a railway to another with the rapidity of a telegraph; and various signs or flags might also remain stationary, as signals to the engineer of the locomotives, when it is necessary to slacken speed, or stop, which may be seen at a much greater distance than the signals at present made by the police: a portable mast might be constructed, to be placed in situations where there was danger, repair, or stoppage. At night, a lamp with a bright light should be placed at the top of the mast, and if any signal be required to be made, another lamp with coloured glass should be hoisted to a certain height, and by keeping the lamp burning at the top, the comparative height of the lower or signal lamp would be more easily distinguished. There should also be fixed a large bell, that signals might be given in hazy or foggy weather, which should be kept constantly ringing when any accident has occurred, until it be answered by the next signal, or the train has passed; probably a gong would be a better substitute for the bell, to prevent mistake from the sound of church bells in the neighbouring towns and villages. Numerous minor arrangements might be made to make the proposed signals efficient and useful.—W. L.

CONTRACTORS' GRIEVANCES.

Sir,—In your address or prospectus, you signify that your Journal is to afford a medium of communication to all parties in any way connected with the profession; as such I hope your pages will be open to the exposure of any abuse of grievance which may be pointed out as having crept into the profession, no matter from what quarter it may come. I am a builder, and believe I have executed as much work as any contractor in England, and am still continuing to do so—the first grievance I have to complain of is the introduction of a new clause into the conditions of specifications, which throws upon the poor builder the whole onus of the failure of construction, no matter from what cause. I do consider that if an engineer or architect be employed, that responsibility should be his; but if it be on account of inferior materials or workmanship, then let it fall upon the builder. Another grievance I consider equally deserving of notice is, that in several large railway and bridge contracts, lately entered into, there has been omitted the design of the centres where the arches are of considerable magnitude, and also the construction of the foundation has been left in a state of obscurity. I do submit that the centre should be subject as much to design and specification as the arch itself, and ought to be as clearly drawn and explained as any other part of the work; and that the foundation should be most particularly described, as the whole building depends upon its security. There are other grievances that I would wish to point out, which I will do at a future time, and conclude by trusting that the profession may not consider me intrusive by making these few observations, and wishing your new work every success.—A CONTRACTOR.

PROGRESS OF RAILWAYS.

Southampton Railway.—Considerable progress has been made within the last three months in the works between London and Kingston, the heaviest part. The embankment across Battersea Fields is in a very forward state; it is now within half a mile of the terminus at Nine Elms. A powerful locomotive engine is employed for removing from 40 to 50 waggons in one train, each loaded with about three cubic yards of soil, taken from the cutting on Wandsworth Common, a distance of about three miles. We have no doubt that the works under the active management of their present Engineer, J. Locke, Esq., will be completed within the time, and for the capital, last reported—we are only surprised that the shares of this Company remain at the heavy discount they do; we have always considered, and still are of the same opinion, that it will be the best passenger line coming into London, and will pay better than any other line in proportion to the capital expended. It is the terminus at Nine Elms which is most against it; they should push the line on to the City, they would then be able to monopolize all the traffic of Wandsworth, Tooting, Richmond, Hampton, and the villages in the vicinity, which they will not do unless the line be extended. Although the short steamers are a great convenience on the river Thames, still the passengers do not want to be danced in and out of half-a-dozen conveyances; besides the delay occasioned by the steam-boats, which cannot convey passengers from Nine Elms to Blackfriars Bridge, including embarking, much within thirty minutes, which might be accomplished by a railway in six minutes: we advise them well to consider of the extension before it is too late. We highly approve of the Company delaying opening the line until next spring, although the works will be ready much sooner; we consider the Directors and Shareholders highly reprehensible, of those companies that so eagerly open their railways to the public before the embankments have had time to consolidate; railways have quite enough to contend with, without the companies creating prejudices against them on account of the frequent accidents and delays that we see reported in the daily papers.

Great Western Railway.—The company are drawing pretty freely on the shareholders, but they are pushing the works very rapidly between Paddington and Maidenhead. Three or four contracts have been advertised last month for the works to be done to the Box Tunnel; we fear they must be undertaken by the company, although we are averse to this mode of proceeding; but the works are of so heavy a character, that we doubt whether they will be able to get responsible contractors to grapple with the undertaking without ...

Birmingham Railway.—The extension line between Euston-square and Camden Town depôt, is now worked by the stationary engines at Chalk Farm, which draw the trains from Euston-square, a distance of one mile, in three minutes and a half, by means of a large rope, which runs on cast-iron grooved pullies about eighteen inches diameter, let into cast-iron boxes, and firmly secured in the ground in the centre of each line of railway; where the line curves, they are canted a little on one side, to allow the rope to follow the direction of the curve. The company talk of opening a further portion of their line, about eight miles and a half, to Tring, on the 10th instant: they had better not be too precipitate; let the embankments be more consolidated; a few such slips as they have had on a portion of their embankment near Watford, may cause the *coroner* to be called into service; the consequences might be serious to some of them. The directors must recollect they have a responsibility which they owe to the public as well as the pockets of their subscribers. What is the reason they allow so many complaints to be continually made relative to the annoyance to the passengers, from the sparks escaping from the chimneys? We hear of no such complaint from other railways; we have just received a letter from a professional friend, who took a trip to Box Moor: he says, "I would not go again for a trifle; I am almost blinded with the ashes; it was the vilest ride I ever had."

Eastern Counties Railway.—Considerable works are going on in the neighbourhood of Old Ford and Bow; a bridge is nearly finished over the river Lea, of one semi-elliptic arch. The span is 70 feet, and the rise one-fourth; the arch is turned in 10 half-brick rims; the centre 12 feet, or crown of the arch, is built in cement; the whole is turned with marl paviors. Another bridge or viaduct of five arches, each 30 feet span, is building near to the above, besides four or five other bridges, under the direction of John Braithwaite, Esq.. Engineer.

Northern and Eastern Railway.—The company are now making a stir, and intend to commence operations, from the London terminus, and proceed to Broxbourn; this portion of the line which will pay them well, they intend to finish first, before they proceed to any other part of the line: *this is a wise proceeding*, and far better than that of some companies, who struggle over the whole line at once *to make a show*, and finish none; it is decidedly best to commence at the terminus, if near a large town, and proceed to finish a short distance of 10 or 15 miles, which may be brought into working condition and pay the shareholders for the capital expended, and then go on again.

The Croydon Railway.—The arches adjoining the junction of the Greenwich Railway are built, and the bridge is now building over the canal—span of arch 40 feet, rise 10 feet, turned in 10 half-bricks set in cement. The works on the heaviest portion of the line (the cutting near Deptford) are proceeding feebly; the Company ought to put their whole strength on this portion of the line, and leave the works at Croydon Common for the present, which cannot be of any service until the above heavy cutting is finished.

Greenwich Railway.—This mill-stone moves very, very slow towards finishing; the directors *report*, that the remainder of the line is about to be proceeded with immediately: there must be some decidedly bad management somewhere. There are sufficient materials on the ground (excepting a few bricks) for finishing the bridge over the High-street Deptford, the bridge over the Ravensbourne Creek, and the viaduct between the High-street and the Creek; but there they lie, and we fear are likely to do, unless some fresh vigour is instilled into the directory.

The Brighton Railways are all aground; they made a regular hotch-potch mess of the line last Parliament, by bartering the best portion of the line to the South-Eastern Railway Company, under the most disadvantageous circumstances; if they wish to do any good, they must get rid of this untoward bargain; we advise them to look sharp, or they will have Cundy's line after all annoying them, probably more than they expect.

Birmingham, Bristol, and Thames Junction.—A contract has just been concluded for building the railway gallery, intended to pass under the Paddington Canal, which is to be diverted and carried over the gallery when built; the contract also includes the building a suspension bridge, or rather a tension bridge, over the canal for foot passengers. W. Hosking, Esq., Engineer. Messrs. Cubitt, contractors. Amount of tender near £8,000.

BUILDINGS AND PUBLIC IMPROVEMENTS.

A Church in the Italian style, with a bell turret, is now building in St. Andrew's burial-ground, in Gray's-inn-lane, under the direction of J. Pennethorne, Esq. The contractors are Messrs. Pearce and Guerrier. Amount of tender about £7,000.

A Church in the Gothic style is being built in the Kent-road, under the direction of Samuel Angel, Esq. Amount of contract about £4,000.

A Church is about to be built in the vicinity of Gough-square, in the parish of St. Bride's.

Two Churches have been contracted for in the parish of Islington. One of them to be built in the Grecian Order, in the Holloway-road, under the direction of Messrs. Inwood and Clifton: amount of tender about £2,000. The other Church is to be built in the Gothic style, with a bell-turret, and vaults, in the Caledonian-road, near King's Cross, under the direction of William Tress, Esq.; amount of tender under £3,200.

It appears by the above tenders that Church building is becoming more and more depreciated: it is impossible to give the Churches any character of architecture—the best is only a make shift. If the Commissioners go on lowering the amount of their allowance, we shall very soon have a new era and style of architecture, to be called "*The Commissioners' Barn-Church Architecture.*"

London and Westminster Bank.—A building in the Italian style, of considerable extent, is now erecting in Lothbury, under the joint direction of W. Tite, Esq. and C. R. Cockerell, Esq. Mr. Grimsdale is the contractor. Amount of tender between £16,000 and £17,000.

Serjeants' Inn.—An additional building has just commenced next to Chancery-lane, corresponding in character with the other buildings that are now finishing. Sir Robert Smirke is the architect, and Messrs. Grissell and Peto are the contractors.

Estimates are now in hand for building the Fitzwilliam Museum; the character of the building is to be Roman, with a Corinthian portico. George Basevi, Esq. is the architect.

Juvenile Prison, Isle of Wight.—The barracks, covering about 4 acres of ground, is in course of being converted into a prison for juvenile offenders. Sydney Smirke, Esq. is the architect, and Messrs. Baker are the contractors. Amount of tender under £20,000.

New Street from the Houses of Parliament to Pimlico. A survey is now being made of the property on the line; we are friendly to public improvements, but we think this is not required. If the Riding-school and the Royal Mews at Pimlico were removed, and two or three houses taken down, a direct line of road would be made in continuation of the King's Road, through Eaton-square, Pimlico, St. James's Park, Great George-street, to Westminster Bridge, and the New Houses of Parliament, which might be formed at one-tenth the cost of the other, and nearly the whole of the line, excepting the portion belonging to Government, is already formed.

Thames Improvement Company.—We have received a pamphlet by Dr. Granville, showing the enormous profit and advantage that might be obtained by saving the manure of the metropolis, which is now allowed to run to waste, impregnating the water in the river Thames, which many of us are compelled to swallow. We are decidedly friendly to any measure that will accomplish the object, and are of opinion that it is perfectly practicable, and ought to receive the strong support of Government. The promoters must be prepared to receive the sneers and scoffs of the public; we are sorry to say that all new improvements in London are generally ridiculed, and it requires the utmost patience and perseverance to carry them into effect.

The Arun Level.—A very able report has been made to the Commissioners of Sewers for the rape of Arundel, by John Macneill, Esq., on the present state of the river Arun, and the means proposed for the drainage of the adjacent country, together with estimates and tide tables.

A Suspension Bridge, with three openings of 700 feet span each, is about to be erected for the Austrian Government, under the superintendence of Tierney Clark, Esq., across the Danube, uniting *Buda* with *Pesth*, in Lower Hungary.

Blackfriars Bridge is undergoing repair, we may say rebuilding, under the direction of Messrs. Walker and Burgess. Two more piers are now surrounded with coffer-dams for the removal of the decayed stone-work, which is to be replaced with Bramley-fall stone; the centre of the bridge is to be lowered about three feet, and the balustrade and cornice are being removed, and instead, a plain parapet is being substituted with the cornice as before, made rather thinner than the old cornice, which we consider is not so well; the columns are being shortened, and the cut-waters raised, which is a decided improvement. It appears that the spandrells and top of the old arch are loaded with rubble, grouted with lime.

Westminster Bridge.—The repairs of this bridge are finished; most of the cut waters and piers have been refaced with Bramley-fall stone, and the top of the piles, which were exposed to the action of the water and the increased rapidity of current in consequence of the removal of old London Bridge, have been cased with stone. We understand that nearly the whole of these works were executed under water by the diving-bell; it has also been necessary to rebuild the facing of several of the spandrells, which bulged out in consequence of the interior of the spandrells being loaded with loose rubbish; every time a load passed over the bridge, the vibration was transferred through the loose rubbish to the spandrell. The works were executed under the direction of the Resident Engineer, F. Swinburne, Esq.

Bow Bridge.—A bridge is being built over the river Lea, under the direction of Messrs. Walker and Burgess. The voussoirs are now being turned; it is a single semi-elliptic arch, the span 70 feet, of Aberdeen granite.

LIST OF PATENTS GRANTED BETWEEN THE 28TH AUGUST AND 28TH SEPTEMBER, BOTH INCLUSIVE.

William Armstrong, of Hawnes, in the county of Bedford, Farmer; for his invention of "Improvements in Ploughs."—28th August, 1837; 6 months.

John Joseph Charles Sheridan, of Ironmonger-Lane, in the City of London, Chemist; for his invention of "Improvements in the Manufacture of Soda." 31st August, 1837; 6 months.

John Hanson, of Huddersfield, in the county of York, Leaden Pipe Manufacturer; and Charles Hanson, of the same place, Watchmaker; for their invention of "Certain improvements in machinery, or apparatus for making or manufacturing pipes, tubes, and various other articles, from metallic and other substances."—31st August, 1837; 6 months.

James Neville, of Clap Hall, near Gravesend, in the country of Kent, Civil Engineer, for his invention of "Certain apparatus or furnace for economizing fuel, and for more effectually consuming the smoke or gases arising therefrom, the same being applicable for the generation of steam, and for heating or evaporating fluids."—31st August, 1837; 6 months.

William James Gifford, of Gloucester-place, in the county of Middlesex, Surgeon; for his invention of "Improvements in Paddle Wheels."—7th September, 1837; 6 months.

Henry Vere Huntley, of Great Russell-street, in the county of Middlesex, Lieutenant in the Royal Navy, for his invention of "Improvements in apparatus for facilitating the securing of Ships' Masts."—7th September, 1837; 6 months.

Thomas John Cave, of Rodney-street, Pentonville, in the county of Middlesex, Gentleman; for his invention of "A great improvement in the construction of Paddle Wheels, applicable to ships, boats, and vessels of all descriptions, propelled by steam or other mechanical power."—14th September, 1837; 2 months.

Edmund Shaw, of Fenchurch-street, in the City of London, Stationer, for "An improvement in the manufacture of Paper, by the application of a certain vegetable substance, not hitherto used for that purpose;" being a communication from a Foreigner residing abroad.—14th September, 1837; 6 months.

Richard Davies, of Newcastle-upon-Tyne, and Robert Chrissop Wilson, of Gateshead, in the county of Durham, Earthenware Manufacturers, for their invention of "An Earthenware Tile Slab or Plate."—14th September, 1837; 6 months.

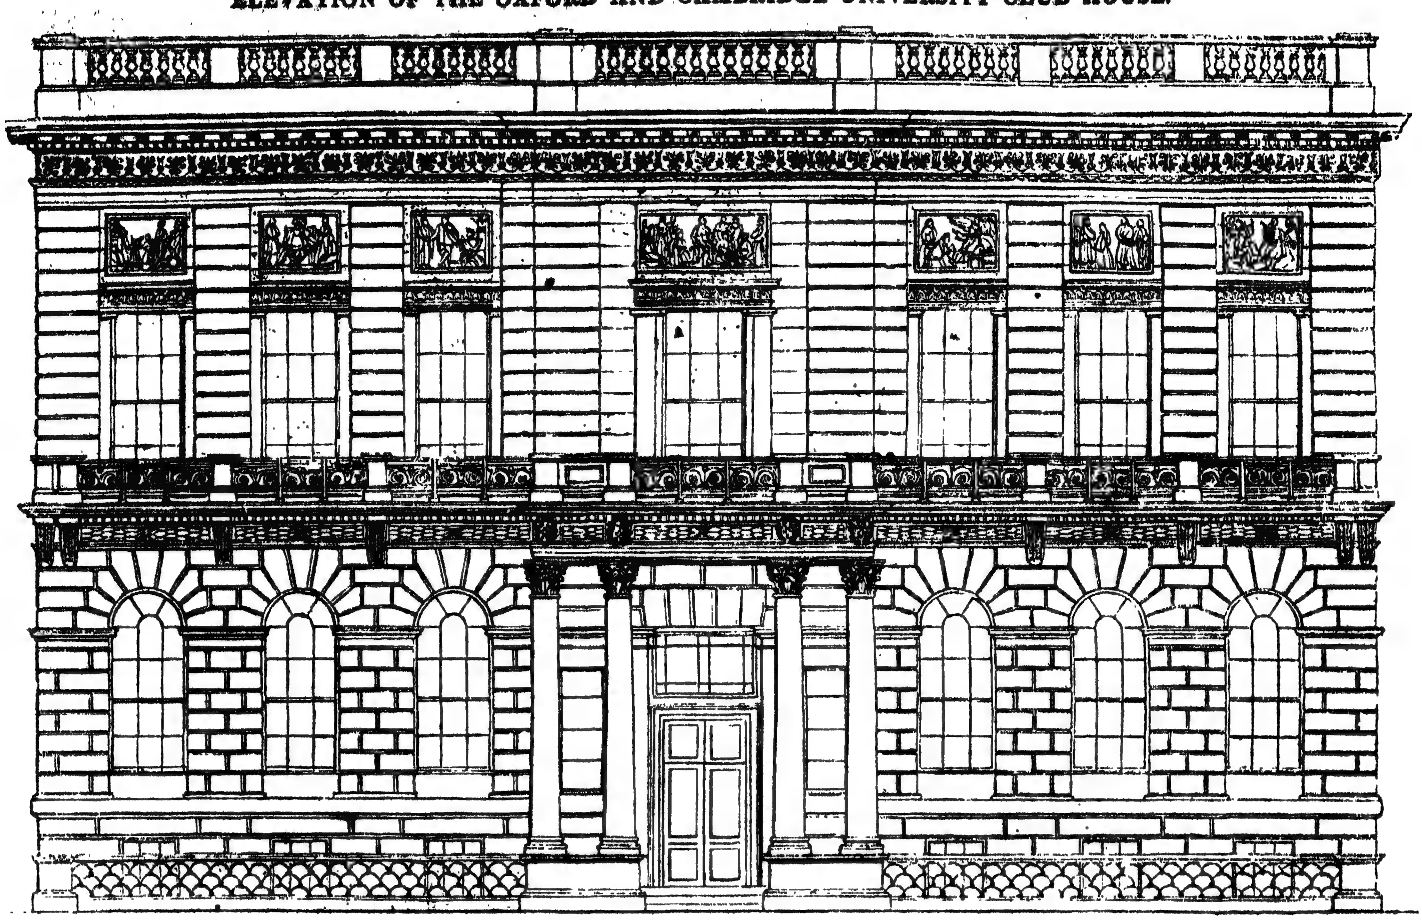
Nevil Sharp, of Bridge Wharf, Hampstead-road, in the county of Middlesex, Wharfinger, for his invention of "Certain improvements in preparing the materials for making Bricks, which improvements are also applicable to other purposes."—21st September, 1837; 6 months.

Samuel Cowling, of Bowling, in the parish of Bradford, in the county of York, Barber, for his invention of "Improvements in raising Water, applicable to various purposes."—21st September, 1837; 6 months.

William Joseph Curtis, of Deptford, in the county of Kent, Engineer; for his invention of "An improved Boiler or Apparatus for generating Steam."—21st September, 1837; 6 months.

Thomas Simmons Mackintosh, of Coleman-street, in the City of London, Engineer, and William Angus Robertson, of Islington, in the county of Middlesex, Gentleman, for their invention of "Certain improvements in Steam Engines."—28th September, 1837; 6 months.

ELEVATION OF THE OXFORD AND CAMBRIDGE UNIVERSITY CLUB HOUSE.



Sir Robert Smirke, R.A., F.R.S., and Sydney Smirke, Esq., Architects.

The Building, the front of which is here described, is erected on the south side of Pall Mall, near St. James's Palace, and is intended, as its name denotes, as a *rendezvous* for Members of the two Universities of Oxford and Cambridge. The front extends 87 feet in width, its height being 57 feet from the ground line to the top.

An entablature, marking the separation of the ground story from the principal floor, and projecting forward in the centre of the building over four Corinthian columns, divides the front, horizontally, into two equal parts. The centre space on the ground-floor is occupied by the portico, which projects to the front line of the area, the centre intercolumniation is wider than the rest, forming the entrance to the hall; the four columns stand upon pedestals, 4 feet high, with base mouldings and cornice. The upper part of the building is terminated with a delicate Corinthian entablature and balustrade, proportioned to the whole height, breaking forward with the centre of the building, which corresponds in width with the portico on the ground-floor; thus the front is divided vertically into three main compartments, the centre being less in width than the other two, which assume the appearance of wings—the effect of a centre, indicated by the projecting portico on the ground-floor, being thus maintained throughout the whole height of the building.

The angles of the centre division, on the principal story, are formed of rusticated pilasters; the principal window occupies the space between these pilasters, which having neither bases nor capitals, produce a uniformity in the lines round the window, giving it the appearance of being contained in a frame. This window, designed with *antæ* in lieu of architectrave, supporting an enriched entablature, is much wider than the rest, and standing clear of the pilasters, with its mouldings to profile, forms in itself a feature in the design. Rusticated pilasters, similar to those already described, divide each wing on the principal floor into three equal recessed oblong spaces, containing the windows, similar in design to the one already described, except that the mouldings to the antæ and entablature do not profile, but stop against the inner side of the pilasters. The ground story is rusticated, and the windows have semicircular heads, with radiating rustics, and impost mouldings. A balcony, projecting 3 feet, continues throughout the whole line of front, and breaks forward with the portico, the parapet being formed of pedestals, with intervening panels of richly-designed foliage, cast in metal in high relief, and the landing supported by elaborately enriched consoles. The frieze of the entablature over the ground story is filled with convex panels, enriched with laurel leaves, and over each column of the portico are shields, bearing the arms of the Universiti es. The whole of the ornamental detail throughout is designed to correspond in richness of effect with the Corinthian capitals of the columns, which have their central volutes entwined. Below the ground story there are two stories, a *Mezzanine* and basement, which are screeend by the area parapet.

The bas-reliefs in the panels above the windows of the principal floor require particular notice; they are executed in Roman cement by Mr. W. G. Nicholl, from designs by *R. Smirke, Esq., R.A.* and illustrate those exalted labours of the mind which it is the peculiar province of the Universities to foster and promote. They recall to mind the sovereignty of Greece and Italy in the divine art of poetry, and the full measure of intellectuality vouchsafed to the inhabitants of this our portion of the globe. In the centre panel Minerva and Apollo preside on Mount Parnassus, a female figure personifying the river Helicon forms part of the group, and pours from an urn the source sacred to the God of verse; the Muses surround them at the foot of the Mount. In one of the extreme panels allusion is made to the popularity of the Iliad, in which Homer is repesented singing to a warrior, a female, and a youth; in the other, Virgil is represented singing his Georgics to a group of peasants: the remaining four panels represent, 1st, Milton reciting his verses to his daughter, inspired by a superior agency seen hovering over him; Shakspeare attended by Tragedy and Comedy; Newton explaining his system; and Bacon recommending his philosophy to his auditors.

Although a description of this architectural composition, and not criticism, is our intention at present, we may be permitted to observe, that it possesses an air of monumental grandeur, admirably suited to a

building, which, from its connexion with the Universities, awakens attention to those proud features of our Constitution; and furthermore, that too much cannot be said in favour of the practice resorted to in this building, of courting the aid of the sister arts to enliven architecture, and reveal the intention of the building; especially when the opportunity offers, as in this instance, of thereby imparting to the edifice a highly intellectual character.

The public, who must ever feel interested in the judicious application of sculpture to buildings erected at the expense of the nation, cannot but applaud that taste and liberality which, as in the case before us, prompt a public display of the art on the part of privatei ndividuals.

Were the love of art more general with us, and did proofs of taste, as diplayed in this instance by the Members of the Oxford and Cambridge university Club House, occur more frequently, buildings would then often become not only entertaining to look at, but highly instructive—the enlivening influence of their mental character would tend to dispel the vacancy and weariness unconsciously produced in the mind by a constant repetition of long rows of unmeaning dwellings.

We had intended to have given the ground-plan of the building, which we are compelled to defer in consequence of the engraving not being ready. It will appear in the next Number, which will also contain a description of the interior.

REVIEWS.

Thoughts on the Experience of a better System of Control and Supervision over Buildings erected at the Public Expense; and on the Subject of Rebuilding the Houses of Parliament. By Lieut.-Col. the Hon. Sir Edward Cust. London. J. Weale, 1837.

We had thought that the brisk pamphleteering in which so many gentlemen, both professional and non-professional, favoured the public with their opinions, pro and con, on the subject of rebuilding the Houses of Parliament, was entirely over; when lo! our attention is directed to that point at our very outset, by these "Thoughts" of Sir Edward Cust's. The title-page is so explicit that it spares us the necessity of explaining what is the purport of the publication; we therefore proceed at once to inform our readers what views the writer entertains, and what course he recommends as most likely to introduce and establish that "better system" which not only is so greatly needed, but seems to be demanded both by the public and the profession. There is, however, another question upon which Sir Edward first of all touches, namely, the very great delay which has been suffered to take place in regard to commencing the new Houses, which, he contends, were it not for very idle procrastination, might at this moment have been in the second year of their progress. We are inclined to join with him in this complaint; for although we would not recommend inconsiderate precipitancy in an affair of so much importance, we could wish to see more vigorous alacrity in setting about and prosecuting so important a work when once decided upon. When fairly commenced, we trust that the works will be carried on with all the expedition consistent with good construction and execution; for although on such occasions the utmost circumspection and foresight are advisable, delays are apt to be exceedingly dangerous. Of this there are many notorious instances, and even where the buildings have not been left in an unfinished state, but ultimately completed, after one or two generations have in the interim passed away, and of course the original architect along with them, they for the most part betray plainly enough, that each architect has in turn innovated upon or departed from the design of his predecessor.

Sir Edward takes no notice of what has been urged—and, that too, rather recently—against the style fixed upon for the new Houses; neither shall we, but come at once to his second and highly important question, viz.—"whether it would be desirable to pursue the same plan of proceeding at any future opportunity when a project of public building shall require to be again considered?" How he is disposed to answer it may easily be guessed; and he fairly enough remarks, that the profession acquiesced beforehand in the course fixed upon; he might have added, that they—at least all the competing architects—acquiesced in the style prescribed to them. There might indeed be many who did not do so very cordially; but then they ought either to have remained aloof, or else have jointly remonstrated and petitioned against it in the proper quarter, while there existed opportunity for altering the conditions, instead of afterwards endeavouring, as some have done, to get the decision set aside, and have the whole business commenced *de novo*.

That the writer should put in a favourable word for amateurs, and assert their competency to decide on the merits of works of architecture, is no more than was to be expected. It may, indeed, be urged, on the other hand, that the judgment of such persons will extend to little more than what are chiefly matters of taste, in other words, matters of art, not of science. Granted; but this amounts to allowing them to be sufficiently well qualified for deciding in regard to that precise species of merit in which the public are most concerned, and wherein one architect most differs from another—that, in short, which is the essence and *sine quâ non* of the art as an art, and without which all other merits stand almost for nothing. "Correctness of eye," observes Sir Edward, "is as much a natural gift as correctness of ear, and a just taste for what is great and beautiful will often be found to preside over architecture, as it is known to do over poetry and music, by those who could as little compose a line or a bar as draw an elevation." This is undoubtedly correct; still, in order to qualify himself as an able critic, a man must sedulously cultivate such natural gift, and familiarise himself with all the niceties of the art—which he may do without a practical acquaintance with construction, although not without some knowledge of its principles.

Perhaps it has happened, that because practical knowledge is indispensable to the professional man, whereas, if he be deficient in taste or art—for art may be considered as the power of manifesting taste—he contrives to shift without it as well as he can, or take it from others at second-hand;—perhaps, we say, it has on this account happened, that those who possess the former without the latter, consider it the height of ignorant presumption in those who possess the latter without the former, to set themselves up as critics.

The relative position of architecture and criticism is precisely the same as it is in regard to the other arts. Those who follow them without manifesting any ability in them, will, whenever they have the opportunity of doing so, deprecate criticism as officious and impertinent—the ill-natured profession of those who cannot do better, or even so well, themselves. Thus is it also in architecture; while the true artist, on the contrary, will look to its approbation as his worthiest and most durable reward.

There are no doubt more pretenders to criticism than real critics, and this is more particularly the case in regard to architecture, in which a superficial knowledge is apt to acquire for a man the reputation of an amateur. How is this to be remedied?—not by attempting to make a mystery of the art, but by encouraging the study of it as far as possible. Let the number of amateurs increase—that is, let the public in general become such—and the monopoly of authority in matters of taste, now enjoyed by a few, will terminate. Mere ignorant pretenders to taste would then either withdraw from the field altogether, or keep silent; while those who wished to be looked up to as leaders in taste would feel that they must exert themselves in order to keep before the rest of the public; in addition to which they would become more circumspect when they discovered, that instead of their opinions being, as at present, received as dicta of high authority, their soundness or impartiality would be constantly liable to be challenged. Besides all which, architects themselves are spurred on to acquit themselves to their very best; feel applause to be more worth seeking, censure more solicitously to be guarded against, when they are aware that the many are able to discriminate between talent and no talent, than when they have to do with an indifferent, drowsy, and but half-awake public.

We have said so much upon this point—one in regard to which there exists such strange misapprehension, as to render it desirable it should be set in its true light—that we have left ourselves very little room for noticing what many may consider far more worthy of attention, namely, the question—"whether every precaution has been taken to give the public the assurance of a good result in the plan selected, and about to be executed?" In Sir Edward's opinion, there are many considerations in regard to the projected pile of building which require to be maturely weighed beforehand. "The public," adds he, "I am sure, will have to thank me for pointing them out, even if it should find that my suggestions have been made in error; since it is of the first importance to know that some competent authority has determined alterations to be necessary and advisable before they have been undertaken." "I desire, then," he afterwards continues, "to impress upon the public the necessity of requiring an efficient supervision over our public works from their commencement; and I would particularly appeal to them not to be led away by the absurd supposition that this control is improper and unfair upon the architect, when it is essentially necessary for our interests, and for that of the public purse, that the same check should be placed upon the public architect, and the needless waste of money, which has been the consequence of his irresponsibility, that is obtained (?) by an individual in his private practice." No doubt there ought to be some sort of check upon the architect of a public work; he ought not to be totally irresponsible; but then neither ought he to be thwarted or fettered; and although it might be expedient in many cases to suggest alterations during the course of the work, we think they ought not to be authoritatively forced upon the architect if he could show that they would upon the whole be unadvisable.

Hitherto one great cause of the jobbing and failures which have

attended so many of our public buildings, is, that they have generally been carried on quite in the dark, without anything respecting them being known until what might have been timely remonstrance and advice, could be no more than the expression of dissatisfaction and disgust. With the intended Houses of Parliament it is otherwise. Here we know at least what we are to expect, and have only to hope that Mr. Barry will not be cramped in the execution of his edifice. A precedent has thus been established that will, we trust, be henceforward followed in all similar cases, or if deviated from, that it will be only by having the designs publicly exhibited for a certain time before the names of their respective authors are divulged, and before the selection of any one of them be actually made. Public buildings are matters that require to be much more carefully attended to and looked after than they have hitherto been, and that not only as regards expenditure, but taste also, for we have ere now had the maximum of the one with the minimum of the other; and making use of Sir Edward's words, "to what," we ask, "can this be attributed, but to the defect in the constitution of that department of our executive to which these matters ought to belong, who have either been superseded in the duties by the interference of a Committee of the House of Commons, or who have voluntarily abdicated their functions, and transferred the whole discretion of a public work upon an officer paid in exact proportion to his own extravagance, without either check or control?"

Temples, Ancient and Modern: or Notes on Church Architecture. By William Bardwell, Architect.

Luckily our first mention of this book was couched in brief and rather general terms, else should we have greatly committed ourselves, for we must now acknowledge, that it has most wofully disappointed us in every respect. We have discovered that the wood-cuts had previously appeared in Brayley's "Graphic Illustrator," and that even most of the plates are likewise taken from other publications; for instance, that of Whitby Abbey from a little book, published in the course of the present year, on the Whitby railway. As regards the former, they serve at least fully to account for the fulsome compliment in the preface to Mr. Brayley of the Russell Institution, though we apprehend, that henceforth Mr. Bardwell will be very shy of that gentleman's "warm-heartedness" and kindnesses, and say—*Timeo Danaos et dona ferentes*. Not content with borrowing, Mr. Bardwell goes a step further —and a most unaccountable step it is—for he actually treats us with a fac-simile of the interior of St. Mary Woolnoth's, in Britton and Pugin's "Public Buildings," with this difference, that in the original the name of Bradberry appears on the plate as that of draughtsman, while here, "W. Bardwell" is substituted for it! That it is a copy and not a fresh view from the same point of sight is evident, because, had the latter been the case, there would infallibly have been some discrepancy between the two; yet now there is not a hair's breadth variation; on the contrary, both exhibit, even to the fraction of an inch every way, precisely the same space. If this be mere coincidence, it is the most miraculous instance of it upon record. Another very odd thing is, that the plates in general have very little connexion indeed with the text; the subjects of some are not even so much as mentioned in it, and others, such as the Mausoleum of Shere Shah, (copied it seems, "by permission," from one in "Elliott's Views in India,") and the atrium of a Roman house, are not so indispensable but that they might have given room to what would have been more useful as well as appropriate in a work on Church Architecture, especially one by a professional man; although we must at the same time confess, the original specimen Mr. Bardwell has given us in his design for a City Church, with the steeple at one corner of the front, does not make us particularly desiderate more. Before we take leave of the "illustrations," as we suppose they must be called, we must remark, that the author has not very strictly adhered to the terms of his prospectus in regard to them; because promise was there made of some coloured ones, instead of which, there is only a single one of the kind, and what it is we defy any one beforehand to guess. Is is some polychrome temple?—some gorgeous shrine?—some Gothic sanctuary, all radiant with hues flung through its rich-stained windows? or some such lavishly decorated piece of architecture at the Capella Borghesiana? Oh no! there would have been nothing at all extraordinary in selecting a subject of that kind, whereas we feel almost stunned and stupified at meeting with a piece of neat waistcoat pattern, buff with narrow blue stripes, which, we are informed, is the fac-simile of the banner borne by Pharaoh when he and his host were drowned in the Red Sea!! This is indeed marvellous, prodigious! as Dominie Sampson would say.

Let us now examine whether Mr. Bardwell has done at all better with his pen, for his book contains 234 ample pages of letter-press, exclusive of preface, there must of course be something in it, or if not, that would, perhaps, be the strangest affair of all. Something in it! truly there is great deal in it that is very little indeed to the purpose, except Mr. Bardwell's chief object was to show how easily a big book may be made, and to give the world a notable example of the art of book-making. How rigmarolishly he treats his subject will be evident at once from the contents of some of the chapters. In the first we have "arguments in favour of limited parishes—attachment to the church—architectural propriety, a cause of that attachment"! Whether this last argument will be greatly relished by the church itself, or taken as at all complimentary, we forbear from inquiring. Chapter II. is on the "Duty of supporting a National Church;"—Chapter III. "On the Advantages of a National Church;"—Chapter IV. "Errors in the Architectural Details of late-erected Churches;" immediately after which follows a chapter on the 'Origin of Architecture." Was there ever a more preposterous jumble? Truly the three first chapters might have very well been omitted altogether, being a work of supererogation; or does Mr. Bardwell fancy that the public require to be roused by him to take into consideration the duty of supporting a National Church; or that, if indifferent to it, their zeal is likely to be awakened by an exhortation from one who comes forward with his ideas for "altering City Churches?" If not an amateur architect, our author is certainly an amateur preacher; yet we would recommend him to desist from his preaching for the future, and stick to what is more in the way of his own profession. What little, however, he does say in one of these chapters on the subject of Churches, is exceedingly fantastical; for he tells us that,

> "A church should be erected at the west end of the Green Park, with a fine portico and cupola, something in the style of the *Superga*, or like the Church of the Assumption at Paris; and another church in the lancet-arch style, with a very lofty spire, near Chesterfield Gate, Hyde Park. These churches are *features* absolutely necessary to that part of the metropolis; and money for their erection should be voted by Parliament, if we would not merit the charge of infidelity or barbarisms now justly urged against us by the stranger, &c."

This is positively ludicrous. Two churches on those particular sites are, it seems, requisite not because there happens to be any need for them, but as "features;" and until they be erected we are justly liable to the charge of infidelity!!! The one which our architect insists upon having built near Chesterfield Gate, is, we suppose, intended for the edification of the Sunday promenaders in Hyde Park, and in order that strangers, when they enter the metropolis on that day, may imagine that those well-dressed crowds are all flocking to their devotions, or else that the church is so crowded within, that there is no room for any of them. We find, too, that not content with assuring us churches ought to be forthwith built on those identical sites, Mr. Bardwell also informs us in what particular style each of them ought to be, which is being very particular indeed. We do not see wherefore he should dictate so long beforehand on that head, instead of leaving the architects to follow their own ideas in regard to style, and if possible give us something more original than an imitation of either the *Superga* or the *Assumption*. Wherefore the other church, if Gothic at all, should be in the lancet-arch style, is a puzzle Mr. Bardwell does not help us to explain.

Although very oddly dragged in, the fourth chapter is one of the most sensible and useful in the whole book; it is, however, almost wholly compilation, and chiefly of remarks upon some of the lately-erected churches, from the "Gentleman's Magazine:" but it would not have been amiss, and certainly not attended with any additional labour, had the respective structures been named; for in these detached criticisms we read of "this tower," "this church," &c., without knowing what particular church or tower is spoken of, consequently cannot always judge how far the remarks themselves are just. Some of these fragments are gleaned from other sources; at least No. 13 is from Fasciculus II. of Candidus's "Note Book," in the "Architectural Magazine;" and as Mr. Bardwell pays it the compliment of saying, that it is "*a most valuable piece of criticism*," he surely might have confessed to whom he was indebted for it. But although here and there he avowedly borrows or quotes, we have detected very many passages where he has unscrupulously and unceremoniously availed himself of the labours of others without acknowledgment at all—not even where he has copied verbatum, and to considerable extent. This sort of peacocking in borrowed plumes is no less dangerous than despicable, and he who condescends to it, runs the risk of being suspected of having stolen more than he can actually be proved to have done. In the very next chapter, which, strange to say, is upon the "Origin of Architecture" —for, if anywhere, the most fitting place for such topics would have been the beginning of the book—we meet with a peacock's feather of some length in the following passage:—

> "Mechanical rules are certainly indispensable to the architect, but to suppose that they are all-sufficient, is nothing short of denying the pretensions of architecture to rank as a fine art. If it can be proved to admit of no other beauties than those already given to the world, and which may be repeated at will; if it have no latent charms responding to the call of master-minds, the sooner we undeceive ourselves as to its real nature the better: let us honestly admit that the world has been imposed upon, and that henceforth architecture must be classed with arithmetic and other studies of that nature, rather than with those pursuits with which it has been hitherto associated. This is what the system of Vitruvius leads to; it attaches *undue* importance to rules, and inculcates a slavish adherence to precedent, while for criticism it substitutes a pedantic jargon, full of impertinences and puerilities; almost making a merit of dulness, it discountenances any attempt at advancing a single step forward, repressing genius, and anxious only to preserve respectable mediocrity, &c."

This passage we have certainly met with before; *where* we cannot positively assert, but think it occurs in one of the architectural articles in the "Foreign Quarterly." Should we happen to be mistaken, Mr. Bardwell can so far correct us, but he cannot possibly contradict us as to his not being the author, although he has passed it off as his own. Even one such gross instance of plagiarism would be discreditable enough; what then are we to say when we find, that with the alteration of a few words, the account of the remains of the Temple at Karnac, at pages 76 and 77, are taken from the first volume of "Egyptian Antiquities," forming part of the "Library of Entertaining Knowledge;" with this difference, however, that it is much less satisfactory, being in fact an abridgment of the other, and omitting many interesting particulars. Now, two writers going to the same source for their information would undoubtedly agree in substance, but certainly not tally so exactly as we find Mr. Bardwell's account does with that in the popular little work above mentioned. Why, as he was not above availing himself of it, he should be above acknowledging his obligations to it, we know not—perhaps

he thought it would be *infra dig* to mention it as authority; yet, in our opinion, it is even more *infra dig* to be caught actually pilfering, and afterwards retailing stolen ware.

Chapter XVIII., which is upon the "Advantages to be derived from the Cultivation of a Pure Taste, and on the Increase of Architectural Taste in England," consists almost entirely of an account of some of the late public works at Paris, given in a letter from M. Le Bas, and, if we mistake not, previously printed in the "Transactions of the Society of British Architects." We do not object to it in itself, for the pages thus occupied are more valuable than almost any others in the whole book, but we certainly do not see what particular connexion it has with Mr. Bardwell's professed subject. However, it is useful in more than one respect, since without it that chapter would have been exceedingly brief and meagre indeed. The "advantages, &c.," are insisted upon in a very common-place way—very much in accordance with the "nothing-like-leather" principle. Nevertheless, we cordially commend what is said respecting its being "the duty of the profession to educate the public eye," and to co-operate for the advancement of their art, abstaining from those petty jealousies to which they have hitherto shown themselves too prone. In all sincerity, likewise, do we applaud the liberal feeling which displays itself immediately afterwards in the following passage:—

"The great number of styles which exist at the present day, though they have not put architecture on the best footing, have yet called forth a greater variety of talent than anciently; and it is to be hoped, that, as those professors disappear, *whose only excellence consists in making exact copies of what they find in books*, the art will become more imaginative and intellectual, and architects will assume their proper rank in society. That architectural taste is rapidly increasing amongst us, it is impossible to deny. The superiority of some of the buildings of the present day over those of the immediately preceding century, proves it abundantly;" [what does Welby say to this?] "and we have a school of young architects rapidly coming forward, whose productions, as exhibited at various public meetings, would do honour to any age or country. I am indeed thoroughly persuaded, that the English people only require to have their attention drawn to the importance of public buildings. One tasteful monarch, one enlightened minister, is able to work wonders in advancing the taste of a whole people. The present illustrious sovereign of Bavaria, with his very limited resources, is doing more for the advancement of the Fine Arts, and consequently laying a foundation for the present and future welfare of his kingdom, than most of the other nations of Europe together."—Pages 188 and 189.

For this well-deserved tribute of praise to Ludwig of Bavaria, Mr. Bardwell must expect to be taken to task by Mr. Gwilt. He has evidently imbibed some of the "Foreign Quarterly" Reviewer's "poison," and is now endeavouring to infect others. Yet how happens it, that notwithstanding he appears to sympathize in opinion with that writer, he has so cautiously avoided in any one instance referring to him, or informing his own readers where they might find further evidence of the King of Bavaria's taste and enterprise? Really we can attribute this marked silence to hardly anything else than the apprehension, that by naming the "Foreign Quarterly," he would have been putting them upon the scent for discovering some of his own plagiarisms. Chapter XIX. and XX. announce themselves as the most important in the whole volume, being entitled "Principles for Building New Churches," and "Interiors." Here we certainly expected to meet with some valuable hints and remarks, particularly as the subject is in itself almost entirely new, and one in regard to which an architect might bring forward several fresh hints. Instead of which, although they would have furnished matter for an entire volume, they are hurried over in a very few pages; yet perhaps we are wrong in saying hurried over, since even those few pages are spun out with much that is irrelevant. There is a good deal of twaddle about a savage's "feeling no want of Homer or Milton," about the Medici Family, Townley, Hope, and Angerstein, but nothing as to whether it would be possible to improve upon the present mode of pewing and putting up galleries in churches, so as to promote, instead of interfering with, architectural character and effect;—also, whether, supposing the style to be Grecian, it would not be far better to light them entirely from above—which might be done according to a variety of modes—and thus get rid of side windows, which, besides being generally injurious to external design, admit sound from the street. Almost all we can gather from what Mr. Bardwell says is, that churches ought to be faced with stone, both withinside and without; that "if the Legislature were to resolve upon the erection of fifty new churches in London, to be built of Irish marble, such edifices would cost the country nothing" !!! and that we ought to "leave off caricaturing Catholic architecture, and make designs in the Italian style, or in the style of Wren's churches." How this latter piece of advice agrees with what is said in the passage we have quoted from page 188, we do not understand; neither do we at all agree with him when he points to Gibbs's church of St. Mary-le-Strand as a happy specimen that the Italian style is susceptible of the utmost enrichment, for, in our opinion, he could hardly have pitched upon a more unmeaning, gingerbread composition.

Chapter XXI. is on "Music in Church Worship;" but we are grateful that it also proves chapter the last, for on coming to that we fancied Mr. Bardwell would not conclude without inflicting upon us a chapter on Preaching.—After all, we cannot part in ill humour from one who has a strong relish for humour himself, and has indulged it so far as to clap opposite to his frontispiece the effigies of old Kraft of Nuremberg, palpably for no other purpose than thus to allude hieroglyphically as the modern Craft of book-making.

Appendix to Elements of Architectural Criticism, in a short Notice of the Foreign Quarterly Reviewer. By Joseph Gwilt. London, 1837.

It is well for Reviewers that there happens to be only one Mr. Joseph Gwilt, for not only does he seem disposed, but plainly threatens, to have the last word with the critic who has given him so much offence in the "Foreign Quarterly," and to whom this "Appendix" is intended as a reply, just as the "Elements" were an attack upon the architectural papers in that periodical. In this literary feud Mr. Gwilt was most certainly the aggressor, and as it appears to us is rather on the losing side of the argument; for on comparing his "Appendix" with the article in the "Foreign Quarterly," intended by way of answer to the "Elements," we find that he has taken no notice whatever of one or two rather material points in the controversy, which, supposing he is able to do so, he would have employed his pen much more to the purpose in refuting, than in pouring forth sentence after sentence of sheer abuse against one who, he affirms, has not the "slightest pretensions even to taste," and whose criticisms, he assures us, are held "in utter contempt." Whether such be the case or not, it is very evident he does not consider him so very contemptible, or he would hardly have published a book expressly directed against that individual Reviewer; on the contrary, he seems to think him a particularly formidable personage, for he actually talks of his "scattering poison abroad." It is a wonder he did not compare him to "the pestilence that walketh in darkness." Were it not highly ludicrous, this would be very hard language for no more heinous crime, than that of admiring Schinkel, and refusing to acknowledge the supremacy of Palladio. In our opinion, Mr. Gwilt could not do better than ship off a cargo of his antidote to Germany, that being the infected land—the country completely "poisoned" with that bad taste which the Reviewer has merely imported from it.

For our part we wonder Mr. Gwilt should take it as any compliment—particularly as there is nothing to make it look like one—that his book was "associated" with that of a German, at the head of the article in the 38th Number of the "Foreign Quarterly." Truly Mr. Gwilt's notion of *association* is pretty much akin to those he has of *poison;* we really know nothing to parallel it except it be that of Mr. Britton, who fancies he is now "associated with Dr. Faraday, one of the most scientific chemists of the present age"! (See the prefatory essay to his "Worcester Cathedral.") But *revenons*—to our great surprise Mr. Gwilt pleads guilty to one charge brought against him by the Reviewer, viz., that of having compared the columns of the London University to a row of skittles or Dutch ninepins. He says, indeed, that he affixed his initials to the "criticism" in question, when first printed in the "Atlas," and afterwards reprinted it with his name at full length. This explanation certainly does away with the reproach of anonymousness; but then it admits by very far the heaviest part of the censure, for criticism must have been sadly at loss and pushed to its last gasp before it could condescend to mere vulgar, unmeaning abuse, which would apply to any other columns—even those of his favourite St. Martin's Church—just as well as Mr. Wilkins's.

In reply to the Reviewer's accusation, that his "Elements" are in fact no elements at all, he now tells us they were intended only "as a few hints." If so, wherefore did he not give that more modest title to his book, instead of affixing to it one that is literally *imposing*, even according to his own confession? At least we humbly conceive there is a wide difference between mere hints on any subject, and elements of criticism regarding it. In our opinion, therefore, Mr. Gwilt would have done well to have treated that part of the Reviewer's answer as he has chosen to do some others—with silent contempt. At present he makes a woful bungle in attempting to excuse himself, by telling us he disavowed in the first page of his book any intention of making it in accordance with its title. In regard to his singular doctrine respecting proportions, he still stoutly adheres to it, not caring to admit that he understands the term very differently from what most other persons do; because orders and different examples of the same order are said to vary in their proportions, although the column and the entablature may be equally well proportioned to each other in all. But as far as we can understand Mr. Gwilt, it matters not whether the columns be four or ten diameters in height, the proportions of the order are the same, provided the entablature be proportioned accordingly.

Among those passages of the Reviewer's to which he has not attempted to reply, is the following:—"Few as the examples actually are which we have of the Grecian Ionic, they suffice to convince us of the great freedom and ductibility of that style, and show more of true architectural invention than all the examples of the Italian orders put together." Are we to infer from his silence, that Mr. Gwilt acquiesces in such *poisonous* doctrine as this; or, that notwithstanding his boast, he is not prepared with an "antidote" against it? Again, he leaves his favourite Italian completely in the lurch, allowing the Reviewer to reproach its Ionic as being "meagre, harsh, and the very reverse of graceful throughout," without putting in a syllable in its defence. "Call you this serving your friends?" Neither does he, when mentioning Schinkel, notice the blunder with which his opponent twitted him, when he called the façade of the Berlin Museum a "meagre display," "all sameness," yet like the composition of a scene-painter—of course scenic. As little does he attempt to defend his unaccountably hypercritical objection against the eagles over the columns of the same façade. Perhaps, out of complaisance to Mr. Gwilt, and with the view of propitiating him, the architect has since caused them to be removed; or if not, Mr. Gwilt is again blundering, for he now speaks of "eagles," not "victories," as applied to the prize of the Wacht-gebäude. Unless we ourselves too are greatly mistaken, he is very greatly so indeed, when he says it is one of the "amusing fancies of the Reviewer," that a person cannot sincerely admire more than one style or school of architecture. Now, our impression is, that in one of his papers, the Reviewer has maintained expressly the contrary, and strongly protested against an exclusive taste for any one style of the art in particular.

Almost had we forgotten to observe, that Mr. Gwilt calls in Goethe as his ally

in the cause of Palladian architecture, hoping by his aid entirely to discomfit his adversary. Now, though Goethe may be quite a "knock-down" authority in matters of literature, it does not follow that his authority is itself unquestionable in questions of architecture. Hardly can Mr. Gwilt have been hoaxed into mistaking him for one of his own profession—yet to be consistent he ought to hold him in scorn as an amateur. He nevertheless scruples not, in this instance, to put more faith in the opinion of such a writer than in that of either Robert Adam or Woods, both professional men, and who have expressed themselves contemptuously enough in respect to the Teatro Olimpico. Since the time Goethe's remarks were penned, a more exact study of Grecian architecture and of the beauties of its detail, has, we suspect, opened our eyes more than formerly to the errors of the Palladian school. Be that as it may, we would recommend Mr. Gwilt to peruse the chapter on Vicenza in a recent work, entitled "Notes Abroad," after which, should his admiration of Palladio continue unabated, he will doubtless take up his pen and inflict a hearty castigation on that most anti-Palladian writer. We would, however, advise the author of the "Examples" to limit his curiosity to that particular chapter, for should he allow it to draw him on to read the work through, he will infallibly stumble upon something infinitely more unpalatable to him.

The History and Antiquities of the Manor House and Church of Great Chalfield, Wiltshire, illustrated by Twenty-eight Plates of Plans, Elevations, Sections, Parts at large, and a Perspective View; forming Part II. of "Examples of Gothic Architecture," Third Series. By Thomas Larkins Walker, Architect. 4to. London: 1837.

Such a work as this refutes, on the one hand, the aspersions attempted to be cast upon Gothic Architecture, and advocates its cause, on the other, with far greater ability than the generality of what has of late been written upon the subject. Pursuing the course originally commenced by the late Mr. Pugin, senior, (whose memory, we cannot abstain from remarking, is deservedly held in estimation by every one for the amiableness of his private character,) Mr. Walker here fully displays to us a most choice specimen of Tudor Domestic Architecture, so beautifully, and withal so fully illustrated, as to be even an improvement upon the two preceding series of the "Examples," which were more desultory in their plan.

"At Great Chalfield," says Mr. Buckler, in his highly interesting little volume on the Palace at Eltham, "the excellences of design and sculpture are united. One of the oriel windows, with a top resembling an ancient regal crown, is more beautiful than any other of the circular shape I have seen. The principal front towards the north is entire, the hand of innovation has not presumed to violate any of its principal features; on the contrary, plastered windows, crumbling walls, crooked turrets, a half-filled moat, and a dilapidated bridge, whose single arch bends across the muddy foss, strongly urge the belief, that this venerable place is resigned to time to effect without a helper the gradual decay of the materials." Such being the case, all the more grateful ought we to feel towards Mr. Walker, whose equally tasteful and accurate pencil has here restored every feature of the original design, and thus not only rescued it from the destruction which probably awaits the building itself, but also put it in most convenient and accessible form for study and reference. Hitherto, on the contrary, it does not seem to have been by any means so generally known as it deserves to be, since even Rickman merely says in regard to it, "*Great Chatfield* House and Mill deserve examination;" but as he has mistaken the name, he probably never saw it.

In this mansion, which Mr. Walker conjectures to have been erected towards the close of Henry the Sixth's reign, most of the windows are pointed, and have arches struck from four centres, with corresponding hood-mouldings. Even the arch of the porch is not enclosed by a square-headed label, but treated the same as the windows; and, like theirs, its hood-mouldings are returned in the form of a square, or escutcheon placed diagonally, by no means a common, although a very elegant practice. Hence, the character differs considerably from that of the later Domestic Tudor, many of whose enrichments, such as string-course, moulded and embattled parapets, and clusters of highly-decorated chimneys, are here wanting. Nevertheless, the composition is so excellent, and the parts themselves, although few, so elegant and appropriate, that nothing seems wanting. Variety, accompanied with some degree of irregularity, does not destroy unity, neither are simplicity and breadth of effect sacrificed to richness—and few things of its kind can exceed in richness the eastern or semicircular oriel, already mentioned in our quotation from Buckler. Whether this happy combination of qualities be entirely the result of study directed by taste, or in some degree likewise of felicitous accident, certain we are, that it cannot be too carefully studied by those who wish not so much to copy this particular style, as to enter into its spirit, and imbue themselves with its feeling. It is this spirit and feeling which the cleverest of our copyists and imitators show themselves most deficient in, and which they should consider no labour too great to attain; and we will further venture to affirm, that where they are absent, it is quite hopeless to look for aught excellent in the way of originality.

In this example, the plainest details are replete with expression; and herein alone, independently of other merits, it is, together with the entire class to which it belongs, immeasurably superior to the puerile, unmeaning gewgaw, and nonsensical frippery of the so-called Elizabethian style, which we are sorry to find so much in favour at the present day among those who are looked up to as the leaders of fashion in Architecture.

With the exception of the very beautiful screen in the hall, and some chimney-pieces, the interior affords little in the way of express decoration; neither would the house itself be at all adapted for a modern residence. There are, however, one or two good ideas in the plan, which an intelligent architect will be at no loss to discover, and to appropriate as opportunity for doing so may arise. As we shall ere long probably bestow some notice upon the First Part of this Series, containing "The Vicar's Close at Wells," we dismiss the work for the present somewhat more hastily than we otherwise should do, but not without congratulating Mr. Walker on having such subjects reserved for him, and still more for the praiseworthy industry and ability with which he has illustrated them.

Guide along the Danube, from Vienna to Constantinople, Smyrna, Athens, the Morea, the Ionian Islands, and Venice. From the Notes of a Journey made in the Year 1836. By R. T. Claridge, Esq. Paris: Galignani. London: F. C. Westley. 1837.

The professional education of the painter, the sculptor, and the architect, was always considered incomplete, until he had visited in foreign countries those splendid monuments of the arts, left to us by the masters of former times, and whose annihilation has hitherto defied the sweeping powers of the scythe of Time. It has been admitted, that a careful examination of these precious relics, of their various beauties and fine proportions, is invariably rewarded by an improvement in the taste and maturity of judgment. If this be so, how desirable it becomes, that every possible facility be given to assist the youthful professor in obtaining for himself these advantages! At present, he too often, from the apparent magnitude of the undertaking, defers from time to time the opportunities as they offer, till at length, through the pressure of professional employment, they are lost altogether. We have been led to these remarks by the small work of Mr. Claridge, which came accidentally to hand, when on a recent visit to Paris. It appears to convey, in a concise manner, the necessary directions for a traveller to make a very interesting and instructive tour at the least possible expenditure of both time and money. To enable him to avoid those delays, difficulties, and dangers, which attend in those parts any attempt to search out doubtful sites of ancient places, and other objects of curiosity, the author confines his attention to such objects only as are well known to be worth seeing along the Danube, at Constantinople, in the Dardanelles, at Smyrna, Ephesus, Athens, the Ionian Islands, and on the way through Italy, by way of Venice, homewards. The author, from his own personal knowledge, states, that the whole of such an interesting journey can be performed within the space of four months, and at the limited expense of less than £120. To effect this, he minutely details the route, and the expenses at every stage of the journey, and sums up or produces a balance-sheet, making the total amount to £114 3s. 2d. He then says,—

> "Thus it will be seen, that a single traveller (whose individual expenses are greater than they would be if he travelled in company with others), taking the best place in the public conveyances, and denying himself nothing to make his journey of the most agreeable description, would find, upon his return home to England, a balance of nearly £6 remaining out of the £120 set apart for his tour."

We have not an opportunity of making extracts from the body of this neat and cheap work. It is, however, full of interesting information respecting the objects worthy of notice, and of their historical associations; for those who contemplate a continental journey, and whose time and means are limited, we would cordially recommend it.

The Artificers' Lexicon for Terms and Prices. Second Edition. By John Bennet, Engineer, &c. London, 1837.

We are at a loss to conceive why the author should call this work a *Lexicon;* the meaning of this word is a Dictionary, and is generally understood to be an explanation or meaning of words, instead of which, the Book is a collection of prices and memorandums; the former, in most cases, are far too high for the present prices, and some are out of all question: for instance, the price in this work of 12 ft. 3 in. best yellow deals is £48 per hundred, which is £10 more than the present price: the prices for plate-glass are double the present charges; to

instance, the price of a plate 85 by 35 inches in this book is £36 1s., the present price is only £18 10s. We are surprised that the author has not corrected this new edition, as his attention was called to those errors when the first edition was noticed in the "Architect's Magazine."

A Treatise on the Strength of Timber, Cast Iron, Malleable Iron, and other Materials. By PETER BARLOW, *F.R.S. &c.* London. JOHN WEALE.

THE name of the author, so justly celebrated for the important works which he has published, and the numerous experiments he has made on the strength of materials, is a sufficient apology for us in calling the attention of our readers to the work before us: it contains the result of numerous experiments which he has made, and minutely enters into all the bearings on the subject, accurately detailing the manner he performed his experiments and their results, together with a collection of numerous tables and experiments made by others. After having explained the various experiments, he draws such practical data from them, which enables any person of a common education to calculate the strength of materials as applied to buildings or machinery.

The importance of a practical acquaintance with the strength of materials is of the utmost consequence, and cannot be too early impressed on the minds of those who are about to enter into the profession, either as an engineer or architect, as it ought, together with a knowledge of construction of buildings and machinery, form a leading feature of their education: we should like to see competent professors engaged by the Institutes, to give one or more courses of lectures on this important branch of Architecture for the benefit of pupils.

"On the Strength of Timber."

"1. There are four distinct strains to which a beam of timber, a bar of metal, or any other hard body, may be exposed, and in which the mechanical effort to produce the fracture, and the resistance opposed to it by the fibres or particles, are differently exerted; while each of these again is subject to various modifications, according to the manner in which the bodies are supported or fixed, the positions in which they are placed, and the direction of the forces or strains to which they are exposed.

"These four distinct cases or strains may be stated as follow:—

"1st. A body may be torn asunder by a stretching force applied in the direction of its fibres, as in the case of ropes, stretchers, king-posts, tie-beams, &c.

"2dly. It may be broken across by a transverse strain, or by a force acting either perpendicularly or obliquely to its length, as in the case of levers, joists, &c.

"3dly. A beam or bar may also be destroyed by a pressure exerted in the direction of its length, as in the case of pillars, posts, and truss-beams.

"4thly. It may be twisted or wrenched by a force acting in a perpendicular direction, at the extremity of a lever or otherwise, as in the case of the axle of a wheel, the lever of a press, &c."

Experiments on the Strength of Direct Cohesion of the Fibres of different kinds of Wood.

There are considerable differences among writers as to this branch of inquiry, particularly in the experiments of Musschenbroeck, which are so different from those of Mr. Barlow, that it must clearly show that there is some decided defect in the performance of the experiments; which may be easily accounted for by the very great difficulty in obtaining a direct force, so as to prevent the material under experiment being fractured by torsion or a transverse strain. Mr. Barlow took considerable pains and trouble to overcome this difficulty, and after having performed numerous experiments, which are detailed in the work before us, he gives the following as the mean result, employing only the nearest whole numbers as *"the strength of direct cohesion on a square inch."*

	lbs.		lbs.
Box is about	20,000	Beech	11,500
Ash	17,000	Oak	10,000
Teak	15,000	Pear	9,800
Fir	12,000	Mahogany	8,000

"*Practical Rule.*—Since the strength of direct cohesion must necessarily be proportional to the number of fibres, or to the area of the section, it follows, that the strength of any rod will be found by multiplying the number of square inches in its section by the corresponding tabular number, as given above.

"This, however, gives the absolute strength, or rather the weight, that would destroy the bar; and practical men assert, that not more than one-fourth of this ought to be employed. I have, however, left more than three-fourths of the whole weight hanging for twenty-four or forty-eight hours, without perceiving the least change in the state of the fibres, or any diminution of their ultimate strength."

On the Transverse Strength of Timber.

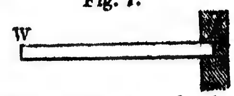
Under this head the author has minutely entered into the various strains to which beams of timber are submitted, and no part of the inquiry on the strength of materials is of greater consequence than this division, as the rules which are deduced teaches us to find the strength of brestsummers, girders, joists, rafters, engine-beams, &c. After having fully and minutely explained the different experiments made by himself and others, on the *laws of deflection*, and the breaking weight of timber, submitted in a variety of ways on timber, deals, planks, and battens, both of the best quality, and of a more common quality, he gives the following:—

"Determination of Practical Data."

[l the length, a the breadth, and d the depth of a beam, all in inches, W the breaking weight, and S the strength in lbs.]

"When the beam is fixed at one end, A, and loaded at the other, W, as fig. 1,

Fig. 1.



$$\frac{lW}{ad^2} = S,$$

a constant quantity for all wood of the same quality, whatever may be the length l, the breadth a, or the depth d; consequently, S once determined, remains the same, and serves for computing the strength of any sized beam of the same wood, or the dimensions necessary to ensure a given strength in a given direction. That is, of the four quantities l, a, d, W, any three being given, the fourth may be found thus,—

$$W = \frac{Sa \cdot d^2}{l}$$

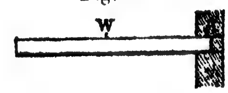
$$l = \frac{Sad^2}{W}$$

$$\left.\begin{array}{l} a = \dfrac{lW}{Sd^2} \\ d = \sqrt{\dfrac{lW}{aS}} \end{array}\right\} \text{In square beams } a = d = \sqrt[3]{\frac{lW}{S}}.$$

"*When supported at one end,* A, *and loaded in the middle,* W, *as fig.* 2,

$$\frac{lW}{4ad^2} = S. \text{ In this case, therefore,}$$

Fig. 2.



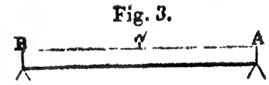
$$W = \frac{4ad^2S}{l}$$

$$l = \frac{4ad^2S}{W}$$

$$\left.\begin{array}{l} a = \dfrac{lW}{4d^2S} \\ d = \sqrt{\dfrac{lW}{4aS}} \end{array}\right\} \text{In square beams } a = d = \sqrt[3]{\frac{lW}{4S}}.$$

"*When the beam is fixed at both ends,* A B, *and loaded in the middle,* W, as fig. 3,

Fig. 3.



$$W = \frac{6ad^2S}{l}$$

$$l = \frac{6ad^2S}{W}$$

$$\left.\begin{array}{l} a = \dfrac{lW}{6d^2S} \\ d = \sqrt{\dfrac{lW}{6aS}} \end{array}\right\} \text{In square beams } a = d = \sqrt[3]{\frac{lW}{6S}}.$$

"*When the beam is supported at both ends,* A B, *and loaded at an intermediate point* W, *as fig.* 4, *the two equal lengths of the beam,* A W, B W, *are represented by m and n,*

Fig. 4.

$$W = \frac{lad^2S}{mn}$$

$$l = \frac{mnW}{ad^2S}$$

$$\left.\begin{array}{l} a = \dfrac{mnW}{ld^2S} \\ d = \sqrt{\dfrac{mnW}{laS}} \end{array}\right\} \text{In square beams } a = d = \sqrt[3]{\frac{mnW}{lS}}.$$

"*When the beam is fixed at both ends,* A B, *and loaded at an intermediate point,* W,

$$W = \frac{3lad^2S}{2mn}$$

$$l = \frac{2mnW}{3ad^2S}$$

$$\left.\begin{array}{l} a = \dfrac{2mnW}{3ld^2S} \\ d = \sqrt{\dfrac{2mnW}{3laS}} \end{array}\right\} \text{In square beams } a = d = \sqrt[3]{\frac{2mnW}{3lS}}.$$

"When the weight is uniformly distributed, the same formulæ will apply; but W in this case will represent only half the required or given weight."

The work contains similar formulæ on the elasticity of timber.

Mr. Barlow has given an extensive table, containing the results of numerous experiments on the elasticity and strength of various species of timber.

From this table we make the following extracts as *the mean result of experiments on the elasticity* (E) *and strength of timber* (S) *selected from the Dock-yard, Woolwich.*

Value of *E* and *S* is from the formulæ

$$E = \frac{l^3 W'}{32\, a\, d^3 \delta} \qquad S = \frac{l W}{4\, a\, d^2}.$$

The experiments were made on bars 2 inches square and 7 feet long, excepting in the second experiments, which were 6 feet long.

Name of Wood.	*Specific Gravity.*	*Value of E.*	*Value of S.*
Teak	745	301,800	2,462
Poon	579	211,200	2,221
English Oak	969	109,200	1,181
Do. No. 2.	934	181,400	1,672
Canadian Oak	872	268,600	1,766
Dantzic Oak	756	148,900	1,457
Adriatic Oak	993	121,800	1,383
Ash	760	205,600	2,026
Beach	696	169,200	1,556
Elm	553	87,480	1,013
Pitch Pine	660	153,200	1,632
Red Pine	657	230,000	1,341
New England Fir	553	273,900	1,102
Riga Fir	753	166,100	1,108
Do. No. 2.	738	123,800	1,051
Mar Forest Fir	696	80,670	1,144

Larch	531	77,040	853
Do. No. 2.	556	131,600	1,127
Norway Spar	577	182,200	1,474

The author proceeds to give a variety of experiments on the strength of timber bent and seasoned by steam, and also the resistance of columns to flexure. After having carefully settled the data, he gives the following

"*Solution of Practical Problems.*

"Having in the foregoing pages established the requisite data and formulæ for determining the dimensions of beams under every variety of transverse strain, it is proposed to give a few examples by way of illustration, in which I shall confine myself to the wood given in the preceding Table of Data, these having been carefully selected, and the experiments made with this particular object."

From these practical Problems (which are most valuable to every one connected with building), we select the following few examples.

"Problem I.—*To determine the Strength of Direct Cohesion of a piece of Timber of any given Dimensions.*

"*Rule.*—Multiply the area of the transverse section in inches by the cohesion per square inch (see Table), and the product is the strength required.

"In practice, the weight the timber has to support should not exceed one-fourth of the strength as calculated by the rule.

"*Example* I.—What weight will be required to tear asunder a piece of oak, 3 inches square?

In this case the tabular value	15000
The area of the section $3 \times 3 =$	9
The weight required	135000 lbs.

"*Example* II.—The diameter of a rod of ash being 2 inches, and its specific gravity 700, what weight will be required to tear it asunder?

The tabular value is	17000
The area of the section $2 \times 2 \times \cdot 7854 =$	3·1416
The product	53407·2 lbs.

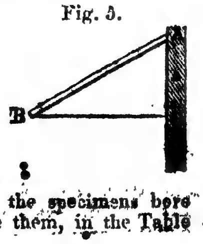
"*Note.*—If the weight be given and the area of section required, it is only necessary to divide the given weight by the tabular value of cohesion.

"Problem II.—*To find the Strength of a Rectangular Beam of Timber, fixed at one end, and loaded at the other.*

"*Rule.*—Multiply the value of S in the Table of Data by the area, and the depth of the section in inches, and divide that product by the leverage in inches, and the quotient will be the weight required in lbs.

"*Note* 1.—In case the beam is inclined, as A B, the leverage is the distance, B C, as fig 5. When the beam is horizontal, the leverage is usually called the length.

Fig. 5.



"*Note* 2.—In practice, the load ought not to be greater than one-fourth of the weight found by the rule; for permanent stretching or displacement of the fibres begins to take place as soon as the load exceeds about one-fourth of the breaking weight. This will be perceived by comparing the weights which the specimens bore without loss of elasticity, with the weights that broke them, in the Table of D ta

"*Note* 3.—If the load be distributed in any manner over the length of the beam, the horizontal distance between the point of support and a vertical line drawn through the centre of gravity of the load, must be taken for the leverage.

"*Example* I.—A beam projecting 5 feet over the point of support, is 6 inches deep and 4 inches in breadth of Riga fir, and is intended to support a load at its extremity; it is required to determine the greatest load it would bear, and the load it may be exposed to without injury.

"For Riga fir, $S = 1108$, and the area being $6 \times 4 = 24$, the depth 6 inches, the leverage 5 feet=60 inches, we have $\frac{1108 \times 24 \times 6}{60} = 2659{\cdot}2$ lbs. the greatest or breaking load; and $\frac{2659{\cdot}2}{4} = 664{\cdot}8$ lbs. for the load it would bear without injury.

"*Example* II.—A cistern to contain 36 cubic feet, or one ton of water, is to be supported by two cantilevers; the projection of the cistern from the face of the wall being 4 feet, it is required to determine the size for the cantilevers.

"Let the cantilevers be of larch, such as the 3rd specimen, then we find by the Table of Data $S = 1127$, and the depth 5 inches. The load on them will be 1 ton = 2240 lbs., and the weight will be uniformly distributed over the length; therefore, the distances of the centre of gravity from the wall will be half the length, or 2 feet=24 inches, which is the leverage. This is the reverse of the preceding operation on account of the weight being given.

$\frac{2240 \times 4 \times 24}{1127 \times 5} = 38{\cdot}2$ inches nearly, for the area of both cantilevers, or $\frac{38{\cdot}2}{2} = 19{\cdot}1$ inches for the area of one of them; and if the section be rectangular, the depth being 5 inches, the breadth will be 3·82 inches for each cantilever.

"Problem III.—*To determine the Strength of a Rectangular Beam of Timber when it is supported at the ends, and is loaded in the middle of its length.*

"*Rule.*—Multiply the value of S, in the Table of Data, by four times the depth in inches, and by the area of the section in inches, and divide the product by the distance between the supports, in inches, and the quotient will be the greatest weight the beam will bear in lbs.

"*Note* 1.—If the beam be not horizontal, the distance between the supports must be the horizontal distance.

"*Note* 2.—One-fourth of the weight found by the rule should be the greatest weight upon a beam in practice.

"*Note* 3. If the load be applied at any other point than the middle, it will be as the rectangle of the segments, into which the point divides the distance between the supports, is to the square of half that distance; so is the weight found by the rule, to the weight the beam will sustain at the given point.

"*Note* 4.—If the load be distributed in any manner whatever over the beam, the centre of gravity of the load must be considered its place, and its stress equal to the whole weight; unless part of such weight be sustained by the supporting points independently of the resistance of the beam.

"*Example* I.—Required the weight a beam of Riga fir, one foot square, would sustain in the middle, its length being 20 feet?

"In this case the tabular value of S is 1108, and the depth 12 inches, and the area 144 inches, the length 240 inches; consequently,

$$\frac{1108 \times 4 \times 12 \times 144}{240} = 32010 \text{ lbs.}$$

And the beam may be loaded in practice with $\frac{32010}{4} = 8002\frac{1}{4}$ lbs. without injury to its texture.

"If the load were applied at 8 feet distance from the end, instead of being applied in the middle, then it would be 12 feet from the other end; and by Note 3, we have $8 \times 12 : 10 \times 10 :: 8002\frac{1}{4} : 8336$ lbs. nearly, for the weight the beam 12 inches square would support at 8 feet from the end; showing the advantage of applying the load as far from the middle as possible.

"*Example* II. To determine the size of a girder of Riga fir for a warehouse, where the distance between the points of support is 18 feet,=216 inches, and the greatest probable stress at the middle, including the weight of the floor itself, 20 tons.

"The tabular number is

$$S = 1108, \text{ and } 20 \text{ tons} = 44800 \text{ lbs.}$$

Let us further suppose that the greatest depth of the timber intended for the purpose is 20 inches. By reversing the rule, we have

$$\frac{4 \times 44800 \times 216}{1108 \times 4 \times 20 \times 20} = 21{\cdot}83 \text{ inches}$$

for the breadth of the girder, which would be obtained by bolting together two pieces, each 20 inches by 11 inches; or much better by putting the two pieces at the most convenient distance apart, that would admit of both resting on the sustaining piece.

"If there be only 20 tons distributed uniformly over the surface of the floor, then a girder of 20 inches by 11 inches would be sufficient.

Similar practical Problems are given on the elasticity of timber, and to determine the dimensions of pillars, &c.

The cohesive power of stone and brick, with a table of the crushing force of various building materials, stone, brick, &c., is next considered.

The next division of the work is on cast and malleable iron. The author has given all the important experiments made by Rennie, Tredgold, Hodgkinson and himself, which are of that consequence as oblige us to consider of them hereafter, particularly the experiments made by Mr. Hodgkinson of Manchester, which were first published in the fifth volume of the "Manchester Memoirs:" they require the attentive consideration of the profession, as they are at variance with the rules laid down by Tredgold, and it appears to us that they are also at direct variance with the opinion of Mr. Barlow, as to the best form of rail for railways.

In conclusion, we cordially recommend this excellent work to the student; in it, he will find much to study, and a great variety of necessary and valuable information.

ORIGINAL PAPERS AND COMMUNICATIONS.

SUGGESTIONS FOR AN ARCHITECTURAL EXHIBITION.

Architects complain that they have not sufficient opportunity allowed them to exhibit their works, or rather designs, publicly; and when we consider, that of all the exhibitions of works of art in London, only two of them admit architectural drawings, this complaint will appear well founded. The two exhibitions which do admit such works, are the Society of British Artists, in Suffolk Place, and the Royal Academy of Arts, late of Somerset House, but now of the New National Gallery. *In the first, by looking over the catalogues of many past years, we find there have been never more than about a dozen in any one year or exhibition, and from the circumstance of these generally being badly placed, it is probable that they only found their way into the exhibitions* from accidentally being of such a size as would cover blank spaces left on the walls, after all the other pictures had been hung—not from any feeling on the part of the Society in favour of Architecture.

At the Royal Academy they certainly have devoted *nearly* one room for this purpose, but it is of such limited extent, that a very small portion only of the drawings annually sent can be placed.

When we take into consideration the large number of architects practising in London, and add the numbers practising in the provinces with their numerous artists and pupils, it may be fairly presumed, that if any encouragement were given, many, if not all, would be anxious to place their works before the public, so that a large and interesting collection would be annually obtained.

There is evidently a feeling abroad in favour of Architecture, which has been fairly proved by the interest excited in the public mind by the exhibition of the designs of the Houses of Parliament. Architects and their friends should not allow such excitement to subside, but make efforts to keep up the feeling, which can only be accomplished by their constantly bringing their works before the eye of the public.

If such an exhibition of drawings as that of the Parliamentary Buildings, nearly all in one style of Architecture, and all of only one subject, and by a very limited number of architects, created such a sensation, and so much discussion, there can be no doubt that an exhibition on a large scale of numerous subjects, in all styles of Architecture, and by a great number of architects, would at least tend to draw the attention of all classes to this delightful and important art.

It must be acknowledged, that the only way of reviving any real love and reverence for the art, is by a general diffusion of its principles amongst the people; and one of the best and most pleasing means that can be employed to draw attention to the subject, is a public exhibition of drawings, showing what has been done, and what the art and architects are capable of accomplishing.

By an exhibition of architectural drawings, it is not meant that they should be confined to mere elevations and perspective views of interiors and exteriors of buildings—but that all drawings, sufficiently well executed, should be admitted, on any subject connected with the art of design, if applicable in any way to architectural purposes. Furniture being so intimately connected with Architecture, should not be omitted. By way of encouraging young architects, certain subjects might be given them to exercise their talents upon, and the whole when done be exhibited, after being placed and numbered in order of their merit by competent judges; and to increase the interest and usefulness of such competitions, the judges should be bound to give briefly their reasons for choosing one design in preference to another.

By such comparative drawings and reasons, the public would see what really constituted good Architecture, and would be afterwards better able to give a proper judgment themselves when called upon to do so in any *real* competition for any public building. In fact, it would be a series of lessons in Architecture, which would be not only useful to the public, but a never-failing source for study and contemplation to the student.

Exhibitions on an extended scale would also be serviceable to the profession in another point of view, for architects could there place those of their designs which had been rejected in competitions, so that the public would have an opportunity of judging whether the best design for any building had been chosen; and the certainty that such an exhibition would be given to all the designs, would ultimately destroy the system of jobbing and trickery, so constantly practised in such cases. By including in the exhibitions designs of furniture, &c., the attention of the ladies might be drawn to the subject of suiting the style of their furniture, fittings, &c., to that of their houses; so that the effect of well-studied interiors might no longer be injured by the introduction of all kinds of incongruities in the shape of furniture.

Let us hope that all architects will combine to establish such an annual exhibition of their designs and drawings, entirely under their own control, as there can be no doubt but that it would not only tend to the improvement of Architecture generally, but would be beneficial to every individual member of the Profession.

EFFECT OF THE WIND ON THE SPEED OF LOCOMOTIVE ENGINES ON RAILWAYS.

The following observations were made upon the London and Greenwich Railway, with a view to determine the effect of the wind upon an engine and train of five carriages, against a strong wind from N.N.W. crossing the line of an angle of about 30 degrees.

The Engine "Royal William."

Diameter of piston 10 inches, 16 inch stroke, wheels 5ft. diameter.

Against the wind . .	$\frac{1}{4}$ mile in 40 seconds =	22 miles per hour.
With the wind . . .	$\frac{1}{4}$ mile in 36 seconds =	25 miles per hour.
Difference . . .	4 seconds	2 miles per hour.

Engine "The Walter."

Diameter of piston 11 in., length of stroke 18 in., wheels 5ft. diameter.

Against the wind . .	$\frac{1}{4}$ mile in 34 seconds =	26 miles per hour.
With the wind . . .	$\frac{1}{4}$ mile in 32 seconds =	28 miles per hour.
Difference . . .	2 seconds	2 miles per hour.

It is here seen, that the difference is not so great as many persons imagine; the quantity of steam used was the same both ways, the regulator being opened as nearly as possible to the same place: the difference is less in the last instance, the engine being of greater power, and the surface exposed less than the first, being without a tender.

A ready approximate method to ascertain the velocity of a locomotive, is to count the number of revolutions of the crank or driving-wheels (if 5 feet diameter) in ten seconds, the number given is the velocity in miles per hour. Thus, if making 30 revolutions, the engine or train are travelling 30 miles, and so on. If the wheels be 6 feet diameter, the number of revolutions in 8 seconds must be taken.

C.

DESCRIPTION OF MR. MITCHEL'S PATENT SCREW MOORINGS AS BEING NOW LAID DOWN IN THE PORT OF LONDON.

Communicated by J. Elmes, Esq., Surveyor of the said Port.

This sort of Mooring is constructed, as its name implies, on the principle of the screw, but differing essentially in form from that well-known instrument; for while the spiral thread makes little more than one turn round its shaft, it is at the same time extended to a very broad flange, the hold which it takes of the ground being proportional with its breadth of disk.

Where it is necessary to provide against a very heavy strain, Mr. Mitchel has moorings of 3 ft. 6 in. diameter, and the principle is capable of still further extension.

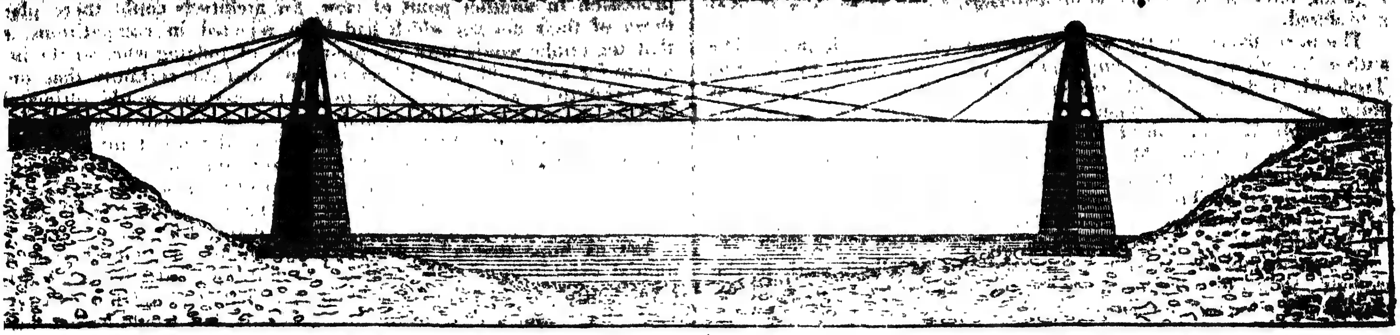
A mooring of the above diameter presents a resisting surface equal to about ten square feet; whereas the palm of the largest anchor in the British Navy does not exceed half that size; and some estimate of its holding powers may be formed, when it is shown that this broad surface can be screwed to a depth many times greater than that to which the palm of an anchor can ever descend.

The method of laying down the mooring is briefly thus:—A strong mooring-chain being so attached to it as to allow the screw to turn freely, without carrying the chain round with it, a powerful iron shaft is then fixed firmly in the upper part of the mooring, which is formed square for that purpose, setting in the same manner as a key to a harp or piano-forte in winding up: it is then lowered by the mooring-chain, joint after joint being added to the shaft till the mooring has reached the ground; light levers of 12 ft. in length are then applied to the shaft in the manner of a capstan, when the operation of screwing the mooring into the ground commences.

Two boats or barges having been moored firmly head and stern close alongside each other, and the upright shaft rising between them about midships, the men place themselves at the bars, and move round from one boat to the other, the two giving them a safe and convenient platform; by a simple contrivance the levers are occasionally shipped upwards, as the screw and shaft sink into the ground.

When the number of men employed can no longer force the screw round, the levers are removed, and the shaft drawn out of the ground, leaving the mooring firmly imbedded with the chain attached to it; a buoy being shackled to the other end of the chain the work is completed, the time required for the

CURTIS'S INFLEXIBLE SUSPENSION BRIDGE.



The principle upon which this bridge is formed, is, that at every point of support its stability is maintained *by four forces*, viz.—the two bars radiating from the centre of each pier, and the frame of the bridge itself, which frame being connected with the piers in such way as to retain only a vertical action, allowing the bridge full liberty to accommodate itself to the changes produced upon the radial bars by their expansion and contraction; at the same time, being confined in a horizontal direction, the inflexible frame becomes a beam, which may be resolved into two forces, acting towards and from each pier respectively, thus assisting to maintain the stability of the structure.

The result of this arrangement is, that the bridge will possess a degree of stiffness and solidity, wholly unattainable by the ordinary mode of constructing suspension bridges.

The frame of the bridge must be formed of timber, well framed together and bolted from side to side, so as to make it as stiff as possible; upon the inside of the pier standards are fixed vertical guides, which allow the frames to rise and fall in harmony with the contraction and expansion of the radial rods, as may be seen in the drawing.

COLUMN DE JUILLET.

Place de la Bastile, Paris.

This proposed magnificent Column, designed to commemorate the celebrated Three Days of July, 1830, is now rapidly progressing. It is being erected on an elevated spot at the eastern end of the Boulevards, the site of the celebrated prison of the Bastile, which was destroyed in 1789, in the early period of the French Revolution. The design first chosen for this noble monument was from the pencil of M. Alavoine, and the present admirably-contrived and well-constructed scaffold employed in raising the present building, was erected under his direction; this person dying in 1834, the business was placed in the hands of M. Lenoir, the present architect. The former plan not having met entire approbation, the latter gentleman was desired to prepare a new design, which is the one now in the course of erection. It will be a Corinthian column, entirely of bronze, standing upon a marble pedestal, the pedestal being surmounted by a colossal figure of a Geni: a staircase will be contained within the column, and a gallery formed above the capital, from whence a fine view of the City of Paris will be obtained. The column will be composed of 22 cylinders or drums, of bronze, each 1 metre, or 3.28 feet in height, and 3.75 metres, or 12.3 feet in diameter; these drums have an internal projecting flange on each end, through which they will be bolted together. The capital will be 1.60 metres, or 5.9 feet in height. The whole weight of metal employed in the construction will be 150.000 killograms (a killogram being equal to 2lb. 3oz. 3dr. 12gr. English). The cost price per killogram for the drums is 3.15 francs, and for the cornices, ornaments, &c., 4.5 francs. The whole estimate for the work complete was as follows:—

	Francs.
For the metallic part	650,000
The marble, &c. &c.	350,000
Total	1,000,000

It may be worthy of notice, that the site occupied by this erection was that which was chosen by Napoleon for the erection of the famous Fountain of the Elephant, the decree for which was dated on the 9th February, 1810, and it named the 2nd of December, 1811, as the day on which the structure should be completed. The foundation was laid in 1810, but to the present day nothing more has been done towards its erection; the model in plaster of Paris still exists within the enclosure, and near the spot where the fountain was to have been erected. This model will give some idea of the fine effect the fountain would have had; its enormous dimensions and fine proportions strike the spectator with admiration, and at the same time a regret that so grand a design should ever have been abandoned. On a recent visit to Paris, we saw the model, probably for the last time; it had lately undergone some necessary repairs, which, we were informed, were the last intended to be bestowed upon it; the shed which hitherto has covered and protected it from the inclemency of the weather is now removed, and if, as we were informed, no further measures are intended to be taken for its preservation, it *will not be long* before the visitor to Paris will merely hear of it as a thing that once existed.

COMMERCIAL DOCKS AT SOUTHAMPTON.

The importance in which Southampton was held in former times, is shown by the date of its charter, of the time of Henry the Second, and the extensive and exclusive privileges which it awarded.

Circumstances are again bringing this town and harbour into prominent distinction—it is computed, that more than 70,000 passengers embark in and land from steam-vessels of various classes at this port in the course of the year; whereas, until the introduction of steam-power to the purposes of navigation, the passage to and from Southampton by sea was confined to the few in their intercourse with the Channel isles, Guernsey and Jersey, or might proceed to and from the Isle of Wight, the usual passage being by Portsmouth.

The effect of the application of locomotive engine power to conveyances by land upon the more eligible harbours of the kingdom remains to be seen, but upon the face of things, it is evident that the maritime trade will be much more divided than it has hitherto been; and such is the force of anticipation, that Southampton is destined to participate largely in this change, as to have led to the establishment of the company, for the purpose of affording the accommodation of Commercial Docks, to be constructed precisely at the spot where the London and Southampton Railway ends, constituting in effect the most desirable and most valuable terminus conceivable to the railway, and at the same time presenting all the accommodation to the trade of the country generally which docks can afford.

It cannot be made too generally known, that the channel from the entrance of Southampton water to the town, being a distance of six miles only, is wide and deep, fully sufficient for any merchant ship to enter the Docks, which are at the foot of the town, unless drawing more than 16 feet water at any time of tide.

It may fairly be questioned, whether any port in the kingdom presents equal facilities for providing the accommodation required for trade, since there is a ready made plateau in which to form the Docks, extending over a surface of 208 acres of ground (exposed at low-water), bounded on two sides by a deep river, that is to say, on the south by the river of Southampton, and on the east by the river Itchin: east of these rivers is a natural and convenient basin, leaving the entire surface of the land applicable to docks and warehouses, the accommodation to be afforded by which may be rendered more than equal to the London and St. Katharine's Docks put together, as will be seen on a comparison of the area enclosed for those Docks, viz.—

London Docks	71	95 Acres.
St. Katharine Docks	24	

The Southampton Dock land will cover 208 acres, every acre being unexceptionable for the purpose in question, and leaving the unfettered judgment of the proprietors to lay out the whole, either for floatage, or warehousing, as the case may require.

The valuable evidence given before a Committee of the House of Lords upon the Bill for making these Docks, fully prove the advantage and necessity of them.

The value of the port of Southampton in a time of war is too forcibly proved, so that it would even justify the patronage of Government toward the Docks, as a measure intimately connected with the national interests; and when it is recollected, that the next war will be a war of machinery—a war, in which steam will produce effects as wonderful and as decisive over the methods and means of the last, as were produced in times past upon the first introduction of gunpowder to the art of war—and when it is remembered again that the peace and security of a nation is guaranteed only by its readiness to go to war, and its ability to carry it on, it is not I think giving to this view of the subject more than its due importance by saying, that it far outweighs every consideration of a mere commercial nature.

The Dock, first and immediately to be constructed, will contain an area of water covering 15 acres and a half—the quay line will be 4,200 feet—and the whole area of this portion of the land is about 50 acres, having upwards of 150 acres for other docks and the accommodation of trade, when required.

NEW STREET TO THE HOUSES OF PARLIAMENT.

Sir,—Perceiving in your first Number that you have noticed the fact of the Treasury having ordered a survey to be made of a line of street connected with my plan for the improvement of Westminster; upon which you remark "we are friendly to public improvements, but we think this is not required." Now as it is possible you may have spoken unadvisedly, I beg to refer you to the Report of a Committee of the House of Commons in 1832, which Report, first showing that the Committee, after a careful examination of my designs and estimates for "Improving the approaches to the Houses of Parliament and Courts of Law, and also for improving the immediate neighbourhood of Buckingham Palace," proceeds to state, "that there is another object of far greater importance connected therewith, the attainment of which must materially conduce to the health of those who reside in that part of the Metropolis." * *

"Upon this subject your Committee request the most serious attention of the House, and of the Government, to a Report made on the 6th of December last, by the Local Board of Health of the united parishes of St. Margaret and St. John, which leaves no doubt of the deplorable state of this part of the Metropolis, with regard to the want of any effectual sewerage, and the dreadful results which must inevitably occur from the pestilential and unwholesome state of the atmosphere in that neighbourhood. Your Committee also refer to the evidence of the Surveyor to the Commissioners of Sewers, who, with twenty-two years experience on this subject, declared, that it was impossible to afford any adequate remedy in the present state of the houses and buildings, but it would be very easy to do so, if improvements of the character contemplated by your Committee were carried into effect." * * *

"Your Committee have carefully examined this plan with reference to the following questions:—1st, Whether it would furnish an effectual sewerage for the greatest extent of ground; 2nd, whether it be the most economical and the most eligible plan which could be devised for improving the approaches to the Houses of Parliament, &c. And your Committee are of opinion, that the plan under consideration, extensive as it undoubtedly appears, *is the most economical and the most eligible which can be devised for accomplishing these objects.*" * * *

"Your Committee therefore strongly recommend to the House and the Government the adoption of this plan, as being, in their opinion, of essential importance to the salubrity of this part of the Metropolis, as materially improving the approaches to the Houses of Parliament and Courts of Law, and as rendering the immediate neighbourhood of the Palace befitting the station of its illustrious inmates."

I might add much upon the nuisances, the levels—part of the district being seven feet one inch below high-water mark—the property of the Dean and Chapter of Westminster, who are unjustly charged with perpetuating nuisances which in reality they are most anxious to remedy. The various plans proposed by other parties, who have evidently but a partial acquaintance with the *locus in quo*, or with the details of the whole subject—the folly of allowing the finest situation in the Metropolis to remain its disgrace—the danger and inconvenience of St. James's Park becoming a permanent public road—the facilities for carrying my plan into execution, and the large profit derivable therefrom (the Exchequer would benefit to the amount of £200,000 from the taxes upon the building materials used);—but as all this would trespass at too great a length upon the valuable columns of your Journal, and as the whole question will again be shortly before Parliament, I will only concur in the truth of your remark "that all new improvements in London are generally ridiculed, and that it requires the utmost patience and perseverance to carry them into effect," and subscribe myself, Sir, your well wisher,

49, Pall Mall, October 18th, 1837. WILLIAM BARDWELL.

ON THE RELATIVE MERITS OF WOOD AND IRON ROOFS FOR STOVES, CONSERVATORIES, AND GREENHOUSES.

The different opinions prevalent with regard to metal or wood for the roofs of houses designed for the culture of fruits, exotic and tropical plants, have led me to inquire into their comparative advantages, having had several years practical experience on the subject, which enables me to speak confidently on the result of my experiments, and the inquiries which I have made.

For more than eight years, I have had the management of his Grace the Duke of Northumberland's forcing and other houses used for horticultural purposes, constructed of wood and cast-iron, and so convinced am I of the superiority of wood, that I feel no hesitation in saying, that when their merits and demerits are ascertained, the erroneous ideas in favour of iron will cease to exist, and I have no doubt that there are many practical gardeners who will confirm the truth of the following observations.

Any persons having a knowledge of the expansion and contraction of metals, may form some idea of the expansion of a large iron roof, on a hot day during the months of July or August, and of the contraction on a severe frosty night: so great have I witnessed the action of the sun's rays in expanding the iron rafters and lights upon a hot day, that it has required two or three men to draw down the sliding-lights, and in an equal proportion have I seen the contraction during the intensity of winter, so much so, that large apertures have appeared between the rafters and lights, which admitted the external air to such an extent, that it required the strength of two fires and the flues heated to the greatest excess before the house could be raised three degrees of heat, and this in a house of not very large dimensions compared with the wood-roofed house I am about to describe.

The dimensions of the iron-roofed vinery was 40 feet long, 16 feet wide, and 9 feet high, with a pine pit in the middle, which very much reduced the cubical contents of the air to be heated.

The wood-roofed house was 50 feet long, 14 feet wide, and 14 feet high, without any pit.

With regard to fuel, the house with the iron-roof at 12 degrees below freezing point required the consumption of 6 bushels of coals, and unremitting attention during the night, or until 1 or 2 o'clock in the morning, at the same time the house with the wood-roof required only 3 bushels of coals to keep it to the same temperature, and no attention was required after 11 or 12 o'clock, when the fires were made up.

I also made a calculation of the number of squares of glass broken in each of the houses, and found a great many more broken in the iron than in the wood-roof, which I attribute to the expansion and contraction of the metal. The last calculation was made after having had the whole of the lights of both houses repaired in the autumn, and in the following autumn it cost nearly double the sum to repair the same number of superficial feet of glass in the iron-roof as it did in the wood-roof.

Moreover, I have invariably found that plants do not thrive nor look half so healthy in an iron-roofed house as they do in one of wood, the iron being so great a conductor of heat, produces the well-known injurious extremes of temperature; and I have always found it necessary to shade all metallic-houses in the summer, notwithstanding their being thrown open, as much as the doors and moveable lights would allow, to prevent the vines or other fruits, when they come in contact with the iron being scorched. I have also observed, that unless the iron-work is painted annually, the drip from the condensed vapour falling from the rusty or corroded iron injures and disfigures the foliage of the plants; in proof of which myself and three other gardeners witnessed last summer, the destruction of nearly the whole crop of grapes and foliage of the plants in a gentleman's hot-house in Kent, erected about five years ago, through not allowing sufficient ventilation, and I advised the gardener, to prevent the same thing occurring in a second house, to make some apertures through the back-wall, about a foot high, and 3 feet long, with a shutter fitted to each, and hung on hinges to regulate the ventilation: he did so, and succeeded in saving the crop.

I think I have fully shown the superiority of wood over iron in several most essential points, viz.—for the better growth of plants, and the saving of fuel, glass, and labour.

I am willing to admit, for lightness of appearance, the iron will have the advantage, but I am persuaded that if proper attention be paid to the formation of wood-houses, they would not be objectionable. I will describe the construction of one, which I think would combine every object required.

The first thing to be attended to, is to give the roof a sufficient inclination to effectually carry off the water and prevent drips, and secondly, to form the roof in the following manner:—

The rafters to be of wood, from 6 to 9 inches deep, and the section to be wedge-shaped (3 or 4 inches wide on the upper, and half an inch wide on the underside); the four sides of the lights to be of wood, the top 4 inches, sides $2\frac{1}{2}$, and bottom 5 or 6 inches wide; and the sash-bars, to prevent as much as possible the obstruction of the sun's rays, should be of copper, which will give the house a light and neat appearance.

I will add a few words to these observations, respecting the heating of buildings with hot water, which is now very generally adopted, and admitted to be the best, most economical, and certain method. The advantages of hot water over steam are several.—In the first place, for generating steam there requires an enormous consumption of coals (a weaker fuel will not do). Secondly, constant attention is necessary to keep up the fire. Thirdly, there is considerable loss of time before the pipes are filled with steam—as steam will not travel through the pipes until the pipe is heated nearly to the same temperature as the steam itself, for the instant it comes into contact with a body colder than itself, it condenses. Water, on the contrary, immediately it is heated in the boiler, circulates through the pipes, and distributes the heat immediately, and continues so long as there is heat in the furnace, which is not the case with steam, for the instant the fire becomes weakened, so as not to generate steam, that moment it ceases to furnish heat to the pipes.

I have devoted considerable attention to heating of houses with hot water, and after examining several plans, and tried numerous boilers, I have at length invented one, which I consider to be the most economical yet made. I have used it in some extensive houses on my own grounds and elsewhere, the drawings and descriptions of which I herewith send you: the smaller boiler (figures 1, 2, 3, and 4) is intended for houses of small dimensions, and the larger one (figure 5) for extensive houses. This latter boiler is circular, and only 2 feet 8 inches diameter across the bottom in the clear of the brickwork, and 3 feet high. During last winter I made use of this boiler; it heated 448 feet run of 3 and 4 inch iron-pipe, which warmed two large greenhouses or stores, 60 feet by 16 feet, and 60 feet by 14 feet; also two pits, 60 feet by 8 feet, and 60 feet by 6 feet—the whole was kept up at their respective temperatures during the severest part of last winter, without any difficulty, or burning a single bushel of coals, the only fuel required was cinders, or very small coke, with the refuse of cuttings from my nursery: at no time did it require more than four bushels of such fuel in 24 hours.

Sion Nursery, Beulah Spa. J. THOMPSON.

THOMPSON'S ECONOMIC EGG-SHAPED BOILER,

(Drawn to a Scale of half an inch to one foot.)

Fig. 1.—Elevation of Boiler.

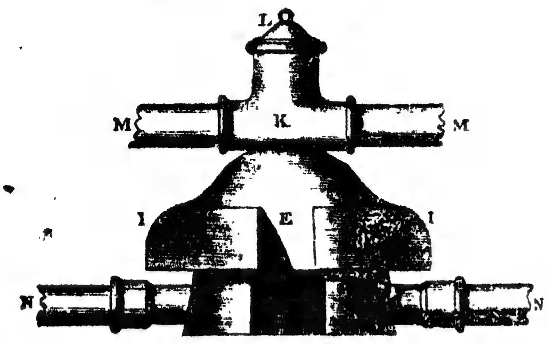


Fig. 3.—Longitudinal Section.

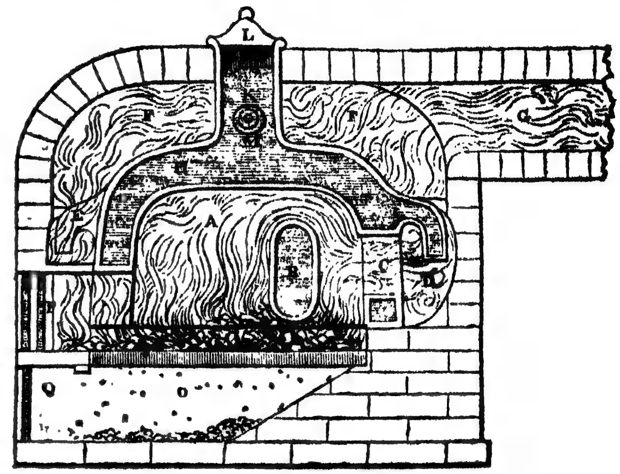

Fig. 2.—Transverse Section.

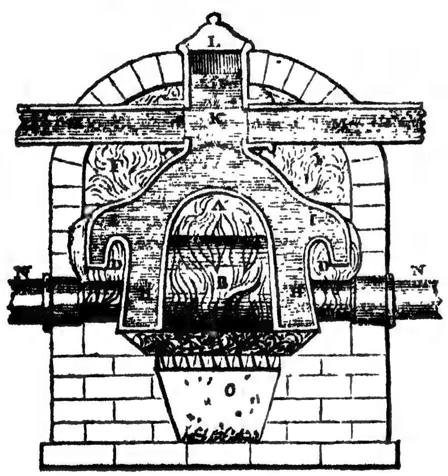

Fig. 4.—Plan of Boiler and Furnace.

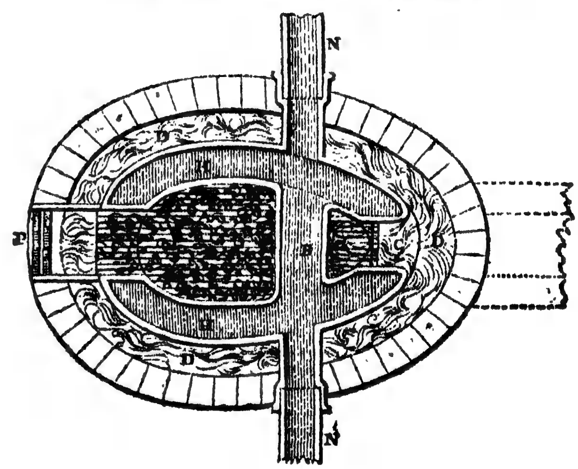

Fig. 5.—Section of Circular Boiler.

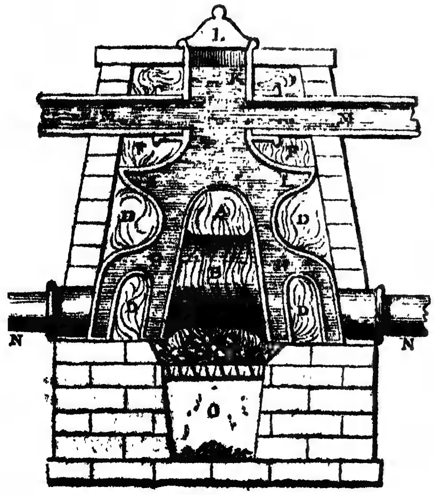

Description of Engravings.

Fig. 1 is the elevation of the front. Fig. 2 a transverse section across the boiler and furnace. Fig. 3 a longitudinal section through the centre; and Fig. 4 a plan of the furnace and lower part of the boiler. The same letters refer to similar parts in each figure.

A is the furnace in which the fuel is placed, entirely surrounded (excepting the under-side) with the boiler: B is a check-draft, over which the heat, flame, and smoke pass to a small aperture C, in the back of the boiler, communicating with the flues D surrounding the lower part, which unite and pass through an opening E in the flange over the furnace-door to the flue F, which surrounds the upper part, and terminates at the brick flue G, furnished with a damper to regulate the draft. The boiler H is in the form of an egg on the plan, with a chamber all round, connected by the check-draft B, and surrounded with the flange I, which divides the upper and lower flues: K is a cylindrical chamber on the top of the boiler, with an iron cap L, either fixed or loose, as may be required: M M are the two outlet pipes communicating with the upper part of the boiler, through which the hot water circulates; after passing to the outside of the brickwork, the pipes are ramified into two or three branches, as may be required for warming different houses, or separate parts of the building; N N are the two return pipes, which enter the lower part of the boiler: O is the ash-pit, with a door, Q, to regulate the draft: the furnace has double doors P to exclude the external air.

Fig. 5 is a section of a circular boiler, with an additional chamber and flue surrounding the lower part.

By reference to the drawing and description, it will be at once seen, that the advantages of this boiler are, the great surface that is exposed to the action of the heat, and the economical introduction of the check-draft and flange filled with water to divide the flues, instead of using stone or brick; and if the flue G be continued through any part of the building to be warmed, there will scarcely be a particle of heat lost.

SCIENTIFIC INSTITUTIONS.

Institution of Civil Engineers.

We have been favoured with a copy of the "*Minutes of Proceedings of the Institution of Civil Engineers, containing Abstracts of Papers, and of Conversation for the Session of 1837.*"

The liberality of this Institution, in allowing their Papers to be published, cannot be too highly commended.

"January 10, 1837.—James Walker, Esq., F.R.S., L., & E., President, in the Chair.

"The President, having called the attention of the meeting to the conversation on Cements which had taken place when they last met, requested Col. Pasley, who had made many extensive experiments on this subject, to give the meeting some account of the results at which he had arrived.

"Col. Pasley said, that his attention had been directed to the subject of Cements from reading in Smeaton's works that all water limes were composed of carbonic acid and clay; since, on dissolving these limes in carbonic acid, clay, of which brick could be made, was left. From this remark he had been led to make experiments similar to the following: he took two parts of chalk and one of clay. The chalk being pounded and mixed with the clay, balls were formed, which being burnt in a crucible, were ground and mixed as cements usually are. Some of these experiments failed, but he attributed their failure to his having used clay which was coarse and sandy; whence it appears that substances will unite when in the form of a fine powder which will not unite when in a coarser form. These experiments were made in the years 1829, 30, 31, and 32. Subsequently, in 1836, he repeated his more successful experiments, but without the same success; and he attributed their failure to the fact of the clay (the blue clay of the Medway) containing a greater proportion of carbonate of lime than it had contained five or six years before. Continuing his experiments, he found that *four* lbs. of dry chalk and *five* lbs. of the moist blue clay, fresh from the Medway, made the strongest cement, but he had determined many other proportions which set immediately under water. With cement made according to the above proportions, thirty-one bricks had been set out from a wall, one brick being added every day, omitting the Sundays.

"He had cemented bricks together, and he found in every case that the bricks gave way and not the cement. He estimated the breaking force at the joints at about 5,000 lbs. on the thirty-six square inches, the surface of the brick. On comparing the strength of this cement with the chalk mortar which had united some bricks more than thirty years, he was led to consider the adhesive power of his artificial cement forty days' old as at least twenty times the power of the mortar."

"January 31, 1837. W. Cubitt, Esq., V.P., in the Chair.

"'*Description and Drawing of an Apparatus designed by Mr. Mitchell for Boring Wells; by Mr. Mitchell, Jun., of Sheerness.*'

"This apparatus consists of a frame, similar to that of a pile engine, in which the rods are suspended; on one of the rods is a wheel fixed on a square spindle (through which the rod can slide), and turned by means of a pinion and crank; the axis of this pinion serves also to draw the rods, since they may be drawn up by a single rope, or by a tackle suspended to the top of the frame, the rope of the block passing round the winch. The auger is regulated in the cut by a screw and nut; thus the rods are always kept from bending in the hole, and the bore from getting out of the perpendicular. This apparatus is found peculiarly convenient in chalk, and when stones are met with; since in most cases, if the auger be sufficiently hard, the stones flash off in small chips similar to gun-flints.

"'*A Method of breaking Ice, by forcing it upwards instead of downwards; practised on the Herefordshire and Gloucestershire Canal in the Winters of 1834-1835 and 1835-1836; by Stephen Ballard, A.Inst.C.E.*

"Mr. B. places strong planks, covered on their upper side with sheet iron, in the front of a boat, so as to form an inclined plane pointing downwards, the lower end of which goes under the ice. The boat, drawn by a horse, is steered by a person walking on the shore with a long shaft attached to a pole projecting over the stern. It is believed that one boat, horse, and boy, would thus break much more ice than three boats worked in the usual manner.

"Mr. H. H. Price called the attention of the Institution to the importance of ascertaining what are really the constituent elements of Artificial Hydraulic Mortars and Cements: several memoirs have been read before the Institute of France on this subject, but they exhibit great discrepancies as to the principles of the formation of these cements. It is of the greatest importance to the engineer to know from the materials at hand how to make a cheap average hydraulic mortar.

"Col. Pasley remarked, that he considered 'Smeaton's Researches' as the only ones of value; the French philosophers had followed out many of his suggestions in great detail. Two systems appear to have been pursued in France, the one in which the substances are burnt previously to their being mixed, the other in which they are mixed in a state of minute division previous to their being burnt. The Aberthaw limestone used by Smeaton consisted of carbonate of lime and clay; *one* part of the lime from this stone and *two* parts of sand make a cement which sets very hard in time, but the joints must be protected at first by Sheppey or some similar cement.

"Mr. Lowe was of opinion that very much must be attributed to the presence of silica; this evidently played a most important part. Limes have exceedingly different qualities; two makers using the same quarry would produce very different limes; if lime is flare-burnt, that is, burnt at a white heat, all the carbonic acid is driven off suddenly; the properties of lime burnt at a slow heat will differ much from the properties of the preceding. The mechanical mixing is also of the greatest importance; the Barrow lime is a natural hydraulic lime, but it must be well beaten with water and silica or sand.

"Mr. Blunt, from America, gave, at the request of the Chairman, account of the system of signals which were employed in the geometric operations now carrying on in America."

"February 7, 1837.—The President in the Chair.

"The conversation on Artificial Cements being resumed, several members expressed their opinions on the causes to which the hardening of mortar was to be referred. Hydrate of lime is the basis of all mortars, but this will not make a water mortar, or cement, without the addition of metallic oxide. The addition of clay will effect this, but most clays contain a metallic oxide.

"Mr. Francis Bramah gave the analysis of Dutch Terras, of Basalts, and of Pouzzolana, according to the different experimenters; in all these there is a considerable proportion of iron; and the addition of any of these to hydrate of lime will make a water mortar. Thus it appears that we must carefully distinguish between a good mortar, and a good water mortar, or cement. Hydrate of lime is the basis of both. Good mortar depends for its excellence on the slow absorption of carbonic acid, and the slow absorption of this is, according to Tennant, the essential condition for good mortar. It is remarkable that, according to Pliny and Vitruvius, the Romans kept their mortar for three years, and it is now the custom among builders to bury mortar, or to keep it in a cellar; it is thus prevented from absorbing carbonic acid from the atmosphere, or, in other words, from being reconverted into limestone. According to some experiments of Tennant, it appears that mortar in 3½ years will regain 63 per cent. of the carbonic acid of which it had been deprived. The absorption of carbonic acid being the condition of mortar hardening, if it be used under circumstances such that this absorption cannot take place, as under water, some other material must be supplied, and the addition of a metallic oxide appears to supply the required element.

"With respect to an hypothesis of Kirwan's which had been mentioned as to the peculiar properties of iron and clay, Mr. J. I. Hawkins stated a singular fact which had come under his own observation, namely, that the rust of iron has a peculiar disposition to travel through moist clay; the rate of this transfer was in one case about *one* inch per month.

"'*On Locomotive Engines, and the means of supplying them. By Jacob Perkins, M.Inst.C.E.*'

"The object of this paper is to show how locomotives may be supplied. The practical defects of the present system of locomotives, arising from the furring up or bruising out of the tubes of the boilers, Mr. Perkins proposes that steam should be generated through the medium of surcharged steam. He states, that if a tube hermetically sealed be filled to $\frac{1}{30}$th of its contents with water, the steam arising from the water will not acquire sufficient elastic force to burst the tube, but will have a remarkable property of transferring heat. The steam being saturated with heat requires no more, and the tube being vertical, this surcharged steam becomes a floating agent through which the heat ascends its own levity, so that the *top* of the tube would become red-hot were it not immersed in water. The difference between pure and surcharged steam is, that surcharged steam gives up its heat without condensing it, whereas pure steam must necessarily condense as it parts with its heat. Mr. Perkins states that a boiler has generated steam on this principle under the action of a fervent heat during the last seven months, and without the least leakage or incrustation.

"Mr. Perkins then details the advantages which may be gained from the adoption of his principles, and proceeds to make some remarks on the manufacture of locomotives. He recommends the division of labour, that the engines should all be fac-similes, and each part be manufactured at the places best adapted for their production. The paper concludes with observations on the most effective application of steam; on the best velocity of the piston, and relative proportions for the diameter and length of the cylinder."

"Mr. Blunt, at the request of the President, then stated some facts respecting the American steamers. The double boats had been given up, and the average speed of the best boats was 15 miles per hour. One boat, whose length is 220 feet and breadth 18 feet, has an average speed more than the preceding. They had recently introduced a ferry-boat, which might, he conceived, be extremely serviceable in our rivers; in the Thames, for instance, where there are a great number of vessels. The boat had bows at each end, so that it could go either way, and rudders at each end worked by one helm; the boat is thus steered at both ends. The rudders are placed in a semicircular chamber at each end, and can be reversed round; they are worked by a chain passing round the wheel of both and crossing in the middle, so that the boat is brought about in the same direction by the contrary action at the two bows. The wheel and chain cannot get out of order, and the rudder begins below the water, so that the boat can go through the broken ice. Such a ferry-boat will go round without going her length, which is about 100 feet.

"Mr. Blunt had repeatedly gone a distance which he knew, from actual trigonometrical measurement, to be 74 miles in 5 hours. The boats completed the distance from New York to Albany, not less than 150 miles, in 10 hours. The speed of these boats, as compared with that of the boats in this country, is not to be wondered at, when it is remembered that the boats are built simply and expressly for speed. The Americans pay great attention to the form of their boats; the water is smooth; the engines are placed on the deck and the boilers on the wings; and they spare no expenditure of power provided speed can be obtained."

(To be continued.)

Specification of the Patent granted to Henry Booth, *of Liverpool, in the County of Lancaster, Gentleman, for certain Improvements in the Construction and Arrangement of Railway Tunnels to be worked by Locomotive Engines.*—Sealed December 3, 1836.

To all to whom these Presents shall come, &c. &c.—*Now know ye*, that in compliance with the said proviso, I, the said Henry Booth, do hereby declare, that the nature of my said invention, and the manner in which the same is to be performed, are described and ascertained as follows (that is to say):—

My improvement in the construction and arrangement of railway tunnels to be worked by locomotive-engines, I declare to consist in the formation of duplicate tunnels near and parallel to each other, but with different and opposite gradients, there being in each tunnel one line of railway, instead of forming, as is usually done, one large tunnel with two lines of railway, both lines having the same inclinations or gradients; and the difference of gradients which I recommend for a general practice is after the rate of twelve to fourteen feet per mile (that is to say)—supposing the tunnelling to be effected be one mile in length, and which, on the ordinary construction hitherto adopted, would consist of one tunnel with two lines of way through it, and that on the ordinary plan the same would be formed on the level, I recommend the construction of two tunnels having each one line of railway descending twelve or fourteen feet in the direction of the moving traffic, which arrangement may be accomplished by raising one out of each duplicate tunnel, and depressing the other six or seven feet from the level line, each tunnel inclining twelve to fourteen feet in the direction of the moving traffic through the said tunnel. Or supposing the tunnelling to be effected be one mile in length, and that, on the ordinary construction hitherto adopted, it would consist of one tunnel with two lines of way, having each an inclination in the same direction of twenty-four to twenty-eight feet per mile, I recommend the construction of two tunnels; one of them (the descending line in the way of the traffic) having the aforesaid proposed inclination downwards of twenty-four to twenty-eight feet per mile, and the other (the ascending line in the way of the traffic) having an inclin tion upwards of only twelve to fourteen feet per mile, instead of twenty-four to twenty-eight feet, as it must have if the two lines of way are in the same tunnel; and the advantage of this arrangement and construction is, that the passage through the tunnel, when on the ordinary construction it would either be on the level or on the ascent, is eased and facilitated to the extent of twelve to fourteen feet comparative declination per mile, that is to say, to the extent of about one-half of the whole force of traction required to overcome friction on a railway. The object to be attained is an easy and quick passage through the tunnels; and as, from the moist state of the rails in most tunnels, the adhesion, and consequently the efficiency of the engine, will be very much diminished, it becomes desirable so to arrange the gradients of the line in the tunnels, by raising or depressing the contiguous portions of the railway, that the passage through the tunnels in each direction may be effected more easily than on the contiguous parts of the road.

By this arrangement it is not proposed to gain any ultimate mechanical advantage, because as many feet as the engine moves downwards (by altering the uniform line of gradients in the tunnel), it must either previously or subsequently move upwards on the open railway; but the advantage is, that you choose your ground, and it being doubly important that no delay should take place in the tunnel, and from the state of the rails, &c., the greatest difficulties presenting themselves at that spot, *I so arrange* the gradients of the tunnels and of the contiguous parts of the roads, that whether on a level or on an ascending line of country, only about one-half the resistance in traction shall be met with in the tunnel as on the open railway; the chances therefore are, that if a locomotive-engine (which is subject to so many casualties) fail in the journey, it will not fail in the tunnel.

Now, though I have named a difference in the gradients or inclinations in the duplicate tunnels of twelve to fourteen feet per mile, I do not confine myself to those exact proportions; one-half this difference would be preferable to no difference; the object to be attained by the adoption of my plan being so to raise or sink the contiguous portions of the railway forming the approaching lines to the tunnels, and the departing lines from the tunnels in each direction, and so to arrange the gradients in the duplicate tunnels, that the passage through the tunnels in each direction by locomotive-engines may be effected as far as depends on the levels or inclinations more easily than on the contiguous portions of the open railway.—In witness whereof, &c.

Enrolled June 3, 1837.

LISTS OF PATENTS GRANTED BETWEEN THE 28TH SEPTEMBER AND 26TH OCTOBER, 1837, BOTH INCLUSIVE.

Francis Hoad, of Demarara, but now of Liverpool, Esq., for "Improvements in making Sugar."—30th September; 6 months.

Jonathan Dickson, of Charlotte-street, Blackfriars-road, Engineer, for "Certain improvements in Steam-engines, and in generating Steam."—30th September; 6 months.

Thomas Clark, Doctor of Medicine, Professor of Chemistry in Mareschall College, Aberdeen, for "An improved Apparatus to be used in manufacturing Sulphuric Acid."—30th September; 6 months.

Joseph Whitworth, of Manchester, Engineer, for "Certain improvements in Machinery, Tools, or Apparatus for turning, boring, plaining, and cutting Metals and other materials."—5th October; 6 months.

Ovid Topham, of Whitecross-street, Middlesex, Engineer, for "Certain improvements in the construction of Sluice Cocks for Water-works, and which improved construction, of Cocks is also applicable to Steam, Gas, and other purposes."—5th October; 6 months.

John Loach, of Birmingham, Brassfounder, for "Improvements in Roller blind Furniture, and in the mode of manufacturing the same, part of which improvements are applicable also to other purposes."—5th October; 6 months.

John Thomas Betts, of Smithfield Bars, London, rectifier, for "Improvements in the process of preparing Spiritous Liquors in the making of Brandy; being a communication from a foreigner residing abroad."—5th October; 6 months.

Antonin Pieux de Riehl, of Vienna, but now residing at Beaufort Buildings; Strand, Middlesex, Engineer, for "Improvements in Steam-engines."—14th October, 6 months.

Thomas Vaux, of Woodford, Essex, Land-Surveyor, for "Improvements in tilling and fertilizing land."—14th October; 6 months.

Henry Quentin Tennesson, late of Paris, but now residing in Leicester Square Middlesex, Gentleman, for "An improved construction of the portable vessels used for containing Portable Gas, and of the apparatus or machinery for compressing such gas therein; and of apparatus or mechanism for regulating the issue or supply of gas, either from a portable vessel, or from a fixed pipe communicating with an ordinary gasometer; being a communication from a foreigner residing abroad."—19th October; 6 months.

Edouard Francois Joseph Duclos, late of Samson, Belgium, but now of Church Lancaster, Gentleman, for "Improvements in manufacturing Iron."—20th October; 6 months.

Henry Robinson Palmer, of Great George Street, Westminster, Civil Engineer, for "Improvements in giving motion to Barges and other vessels on canals."—20th October; 6 months.

John Frederick Grosjean, of Soho Square, Middlesex, Musical Instrument Maker, for "Certain improvements on Harps, which improvements are applicable to other Musical Stringed Instruments."—20th October; 6 months.

Miles Berry, of Chancery Lane, Middlesex, C.E., for "Certain improvements in the preparation of Palm Oil, whereby it is rendered applicable to the woollen manufactures, lubricating of machinery, and other useful purposes to which it has not hitherto been applied; being a communication from a foreigner residing abroad."—26th October: 6 months.

Miles Berry, of Chancery Lane, C. E., for "Certain improvements in machinery for heckling or combing, and preparing and roving hemp, flax, tow, and such other vegetable fibrous substances; being a communication from a foreigner residing abroad." 26th October; 6 months.

Meeting of Scientific Societies.

The Architectural Society....................Thursday, 6th November.
The Institute of British Architects..............Monday, 4th December.

LAW PROCEEDINGS.

COURT OF COMMON PLEAS.—Oct. 26th.

[London Sittings, before the Chief Justice and a Special Jury.]

THE DIRECTORS OF THE STANHOPE AND TYNE RAILWAY *v.* HARFORD AND OTHERS.

This was an action brought by the plaintiffs against the defendants for a breach of contract, and the cause of action arose in the following circumstances:—The plaintiffs had caused an advertisement to be inserted in the newspapers on the 9th of September, 1832, for the supply of 3,000 tons of cast iron rails, one-half at the rate of 30lb. and the other half at 40lb per yard, with the requisite quantity of chairs, rails, pins, &c., "to be made of the best iron, which, when worked, must be equal to No. 3 bar-iron, and the chairs to be made of No. 1 bar-iron." The advertisement was replied to by the defendants, who are extensive iron manufacturers, carrying on business under the name of Harford, Davis, and Company, of Bristol, and also near Newport, in the county of Monmouth. The acceptance of the tender, which was made by the defendants in the words of the advertisement, was dated the 20th of October, and it only remained to settle the pattern of the chairs, some railway companies using one description and others a different pattern. In the month of January following, after some correspondence, the pattern was agreed upon, and a gentleman was deputed by the plaintiffs to visit the defendants' works, for the purpose of seeing the description of iron to be used in the process of manufacture, in order to guard against mistake or deception. On his arrival in South Wales some of the furnaces were set to work, and he found that a quantity of refuse, or cinder iron, was introduced along with the mine or ore iron, and he accordingly objected to it, and ultimately gave notice to the defendants that the plaintiffs would not receive that description of manufacture. The plaintiffs had a communication with the defendants, protesting against the article of "cinder" being used, and two of the directors went down to repeat their objection. A very lengthened correspondence ensued, the result of which was, that the defendants presevered in manufacturing the articles in their own way, and notice was given them that the rails would not be received. The plaintiffs advertised again, and made a contract with another party upon the best terms they could, but the price of iron had in the mean time risen, and the present action was accordingly brought for the difference between the price stipulated in the contract with the defendants, and that actually paid by the plaintiffs. This loss they estimated at £8,081. The main question in the cause regarded the construction of the contract. *On behalf of the plaintiffs it was contended, that the defendants were required by it to furnish rails made only of pure or mine iron. The defendants' case was, that the terms of the contract did not preclude them from using a certain portion of cinder in the manufacture of the iron rails.* A large number of witnesses were produced on each side. Amongst those called by the plaintiffs were Mr. Bramah, Dr. Ewer, and Mr. Story, who stated not only that the terms "best iron" precluded the use of cinder, but that the cinder was positively detrimental to the quality of the iron; whilst, for the defendants, a considerable number of ironmasters, amongst whom were Mr. Guest and Mr. C. Harford, expressed a directly contrary opinion. On behalf of the defendants it had also been urged, that no binding contract had been completed between the parties, but that point, depending upon the construction of a lengthened correspondence, was reserved or the decision of the court below.

The Lord Chief Justice summed up, and left it to the jury simply to decide between the conflicting statements of the witnesses as to the construction of the terms of the contract. If they should be of opinion that the defendants, by persisting in their intention of using cinder in the manufacture of the rails which they contracted to furnish, had refused to comply with the terms of the contract, they must find their verdict for the plaintiffs; but if, on the other hand, they should be convinced that the "best iron" might be composed of a portion of cinder, and that consequently the defendants were only prevented from fulfilling their engagement by the conduct of the plaintiffs themselves, the defendants would be entitled to a verdict at their hands.

The jury returned a verdict for the defendants.

Railway Shares.—Last month, two actions were tried before Sir Charles Wethorell, the Recorder, involving questions respecting the sale of railway shares. The first cause, "England *v.* Seaton," was to recover the difference in value of certain Great Western Railway shares, which the plaintiff had contracted to take off the defendant's hands on indemnity from him, and in which a verdict was taken by consent for 100*l.* The second action, "Lawrence *v.* Biggs," was to recover back 21*l.* 7*s.* 0*d.* paid for Bristol and Gloucester Railway shares, in which a verdict was given for the defendant under the direction of the learned Recorder, who, during the whole progress of the case, had expressed an opinion that the plaintiff could not

recover, on the ground of the defendant being his authorized agent for the purchase of those shares, and effected the purchase in pursuance of his instructions.

Taff Vale Railway.—An inquisition was held at the Angel Inn, in the town of Cardiff, on the 12th ult., before the Sheriff of this county and a respectable jury, for the purpose of assessing the value of some premises required for the railway. The first case was that of five houses, gardens, and yards, at Newbridge, the property of Mr. John Williams, which he had valued to the company at the rate of 1,100*l.* Mr. Williams, had been offered by the company at the rate of 500*l.* for it. After hearing witnesses on both sides, the jury assessed the value at 420*l.*—The next case related to some coppice-wood, the property of W. Wills, Esq. For this property, the company had tendered 100*l.*, which was refused, and the jury assessed the value at 90*l.* In consequence of the amount awarded being less than the sum offered, the party will, under the Railway Act, be liable to pay half the costs of the inquisition, witnesses, &c.—*Merthyr Guardian.*

STEAM NAVIGATION.

"On the 14th ultimo was launched *the splendid new steam-ship, "Liverpool,"* which for a length of time past has been building for Sir John Tobin, at Humble and Milcrest's yard, in Liverpool. As a specimen of naval architecture, this is the most splendid we ever saw in the port of Liverpool. She is with one exception the longest in the keel of any ship laid down. She was built in a kind of dock made for the purpose, and for several days the workmen were busily employed in clearing away and preparing for the launch. The ways were laid down 90 feet beyond the usual length. The ship measures 240 feet in length from her figure-head to her traffrail, and 57½ feet over her paddle-boxes. She is 1,042 tons by admeasurement, but will carry a cargo of 1,500 tons; her depth of hold is 20 feet. When completed she will cost at least £45,000. She has occupied the builders 12 months in building. Her two engines are of 460 horse-power, and are now in progress of construction by Messrs. Forrester and Co., of Vauxhall Foundry, and will not be completed for some months. The model of the vessel is exceedingly elegant, and has been greatly admired; her figure-head is the full length figure of a man.

Launch of an Iron Vessel.—On Saturday last, the *Rainbow*, an iron steam-vessel, built for the General Navigation Steam Company, was launched from Mr. J. Laird's yard, Birkenhead. She is, with two or three exceptions, the longest steam-vessel built or building in this country, her dimensions being—length over all 213 feet; beam, within paddle-boxes, 25 feet; extreme width, 49 feet. She is divided into six compartments by five water-tight partitions, which entirely remove all danger of sinking in case of collision with other vessels; and if all the other advantages iron vessels possess are left out of view, the simple fact that in them these partitions can be rendered most efficient and secure will, we have no doubt, cause their general adoption, both for sea-going and river vessels. The *Rainbow* is now being fitted, by Messrs. Forrester and Co., with a pair of 90-horse power engines; and her cabins, which are of the most spacious and elegant description, being also in a forward state, we may shortly expect to see her at work, and have no doubt, from superior model and light draught of water, she will be one of the fastest steamers afloat. The *Rainbow* is the tenth vessel built by Mr. Laird with water-tight compartments; and we understand that he has now three other large ones building on the same principle.—*Liverpool Advertiser.*

The Gordon Steam Packet.—This splendid vessel, which was launched at Pembroke in August, has been fitted with two engines of 110-horse power each. Her armament has also been completed, and consists of 14 long 32-pounders, and two 84 pounders on circular sweeps. She will either steam or sail.

ENGINEERING WORKS.

RAILWAYS.

London and Birmingham Railway.—On the 16th ult., a farther portion of this railway was opened to the public from Box Moor to Penley Heath, near Tring, making a total distance of 31½ miles of railway now opened from the Euston square station. We observe on a portion of the line they are removing the longitudinal timber sleepers, and substituting granite sleepers, and in another part they are exchanging the chairs at the joints, for a new chair invented by Mr. Buck, the resident engineer; the rails in the other chairs are secured by wooden keys. We will endeavour, in our next Number, to give a drawing of the new chair, also an architectural description of the line now open to the public.

Great Western Railway.—It was stated that the railway from Paddington to Maidenhead would be open early this month; we connot see how it is possible to have it ready this side of Christmas.

Greenwich Railway.—The remaining portion of this line from High-street, Deptford, to Greenwich, is to be proceeded with immediately. It is stated that Mr. Macintosh has contracted to carry on the whole of the works that are to be done. The stone sleepers now on the ground are advertised to be sold, and instead of them it is intended to use longitudinal timber sleepers.

The Dublin and Kingstown Railway.—The stone sleepers are being removed, and longitudinal timber sleepers substituted; also the rails are being exchanged, and a heavier rail laid down instead.

Brighton Railway.—As the new session of Parliament approaches, so do the different Companies of the rival lines again begin to place themselves in battle array, and to all appearance there will be another effort to bring in next parliament, either Stephenson's or Mills's line. A meeting of the shareholders of the latter Company was held on the 29th ult., to consider the propriety of going to Parliament in the ensuing session. Mr. Stephenson has issued another Report (which was placed in our hands as we were going to press); the intention of it is to show, that Captain Alderson has drawn wrong conclusions as to the several points reported by him to the House of Commons regarding the "direct line" and his own line: to all parties interested, we recommend to them a perusal of the Report.

Manchester and Leeds Railway.—Contracts have been advertised for the works to be done in the neighbourhood of Rochdale, Littleborough, Horbury, and Wakefield. The works near Mills Hill, between Middleton and Oldham, are proceeding night and day; small waggons, drawn by one horse each, and constructed upon a new method, so as to contain three cubic yards of earth, are extensively employed, and they are found to facilitate the progress of the works in a material degree.—*Manchester Courier.*

Birmingham and Derby Junction Railway.—Contracts have been advertised for the works to be done in the neighbourhood of Stonebridge, Maxstoke, Kingsbury and Elford.

Great North of England Railway.—The contract for building the bridge over the river Tees, in the southern portion of the line, was let on the 10th ult. to Messrs Dees and Hoy, of Newcastle. Tenders were to be delivered in on the 31st ult. for making eight miles and a half of railway from Darlington to Birkly.

The London and Birmingham Railway Company have it in contemplation to apply for a bill next session to make a market at the Camden Town terminus.

Grand Junction Railway.—Tenders are required for buildings and works connected with the passenger station at Birmingham.

North Midland Railway.—Operations have commenced on a portion of the line little beyond Heath Common, near Wakefield.

Taff Vale Railway.—Tenders are required for a portion of work to be done on this line.

Leith and Edinburgh Railway.—This undertaking is now fairly begun, and some progress made in the cutting and embankment immediately below Warriston-crescent in a line with Scotland-street.—*Stirling Journal.*

Extension of English Railway line to Scotland.—At a meeting of the Merchants Company, held on the 16th ult., it was unanimously resolved, that a memorial should be presented to Government, urging upon them the policy of having a survey made, under the direction of the Ordnance, of the best line for a railway wherewith to connect the capital of Scotland with one of the great leading English lines now being constructed.—*Edinburgh Observer.*

North Union Railway.—The works on this line are at present making rapid progress at the Wigan end. The erection of two iron-bridges, one over Walgate and the other over Chapel, are now in progress, and they are expected to be an ornament to that town.—*Preston Chronicle.*

Manchester and Birmingham Railway.—At a special meeting of the Directors of this Company, held on Saturday, the 7th ult., John Urpeth Rastrick, Esq., was appointed engineer to the Company.

The Austrian Government has at length resolved on executing a double project of vast utility to its Italian possessions—that of establishing two railroads; one from Vienna to Trieste, and the other from Venice to Milan. A regular weekly steam-boat communication is already established between Trieste and Venice, and this station is to receive an adequate augmentation of its efficiency when the railroads are finished. The railroad from Venice to Milan is to be subdivided into three branch lines. The first, sixty-two leagues in length, will intersect the whole Lombard Venetian kingdom; the second, about the same length, will traverse Mantua, Lodi, the Milanese, and the whole of Lower Italy; the third, sixty-four leagues in extent, will traverse the rich vicinity of the Lake of Guarda, and pass the great towns of Brescia, Padua, Viconza, and Verona. It is calculated that the travelling rate of transit by the various branches of this railroad will be a mile in four minutes, including the requisite stoppages; and that the whole expense of the undertaking will be fifty millions, towards which twenty-eight millions have been already subscribed by Venice, and twenty-two by Milan.

Continental Line of Railroad.—The great conception relative to the establishment of a great continental line of railroad across North Germany is in progress of execution. The line of railroad in Belgium extends to the frontiers of France and Prussia, from Ghent to Aix-la-Chapelle. France is hesitating; but Prussia is opening fifty German miles of railroad, which will afterwards be extended to her capital. The Company of Railroads of the Rhine and the Weser have obtained the concession, and are setting to work upon it. Doubts and obstacles disappear. It was said, indeed, that in Germany the expense of railroads would be enormous, and the profits small; and the expense of 233,000 thalers per mile expended on the Belgian railroad was cited, with the trifling profit of 13 per cent. But these are easily answered. In Belgium they counted only on 70,000 passengers, yet they were obliged to make a second line to accommodate the increased number. In North Germany, too, the country is much flatter, and the cost per German mile will not exceed one-half of the expense in Belgium.—*Augsburg Gazette.*

Railroads in the United States.—From the statements of Professor Henry, at the late Liverpool meeting, it appears that there are now 1500 miles of railroads in active operation in the United States, and 2000 miles of canals. Upwards of 3000 miles more of railway are in progress, although they have been greatly interrupted by the late commercial convulsion.

The Grand Canal Tunnel at Coseley, near Bilston.—The Grand Canal Tunnel at Coseley, near Bilston, which forms part of another important work undertaken by the Birmingham Canal Company for the improvement of their navigation, was open to the public on the 6th instant. In the construction of this tunnel, care has been taken to obviate the delays and inconveniences experienced at narrow tunnels on many of the old canals. The waterway being 17 feet in width, and a horse towing-path being provided on each side, both horses and boats are enabled to pass through it either way uninterrupted at all hours; and the severe labour to which boatmen are subjected at narrow tunnels, in propelling their vessels by the process called "legging," is, as regards this tunnel, entirely superseded. By the completion of the new or improved line, of which the tunnel forms a part, the direct canal route between Birmingham and Wolverhampton has been further shortened four miles; and when the other works now in progress shall have been completed, the route will be equally short with the turnpike-road. The cost of the line now opened exceeds £65,000.—*Wolverhampton Chronicle.*

Severn Navigation Improvement Company.—A meeting of the shareholders of this Company was held on the 12th ultimo, at Worcester. In consequence of the difficulty of raising sufficient capital to carry the original intentions of the Company into effect, the plan for forming a ship navigation from Gloucester to Worcester, by making the River Severn 12 feet deep, was abandoned, and instead thereof, a resolution was carried for forming a new Company to obtain a bill for making the River Severn from Gloucester to Worcester, 6 ft. 6 in. deep, and from Worcester to Stourport, 6 feet deep with all necessary locks, weirs, and cuttings, for a barge navigation, agreeable to the Report of W. Cubitt, Esq.

Projected Line of Canal.—For some months past, parties have been actively engaged in the survey of a new line of canal, intended to connect the towns of Altrincham and Middlewick by a less circuitous line of traffic than that which at present exists. The distance by the present route of canal, between the two points, is about forty-four miles; and by the intended line, branching out of the Bridgewater at Altrincham, approaching within a couple of miles of the town of Knutsford, and joining the Trent and Mersey Canal, at Middlewich, somewhere about 26—thus would a saving of eighteen miles be effected in a distance of 44! The survey is going on very successfully; when that is completed, and the scheme itself wholly matured, the public will, we are informed, be made fully acquainted with the project.—*Macclesfield Courier.*

New Houses of Parliament.—Considerable progress has been made in the coffer-dam during last month; the bed of the river, the whole length of the dam, has been dredged, and nearly all the main piles driven.

Hastings.—A sea wall, 1,000 feet in length, is being built in front of the Priory Grounds, at Hastings, for Her Majesty's Commissioners of Woods and Forests. Messrs. Walker and Burgess are the engineers. Amount of contract under £2,000.

Kingstown Harbour.—Considerable works are in progress in the New Harbour. A new Steam Boat Wharf has been built for landing and embarking passengers at all times of the tide.

Hull.—A new Steam Engine Manufactory, to be named the *Cyclops*, is building for Messrs. Brereton and Vernon.

Swansea.—A Floating-harbour and Dock is immediately to be formed, under the direction of H. Habberly Price, Esq., Engineer.

Level of Felpham and Bognor, in the county of Sussex. Tenders are required for making a new Sluice, about 350 feet long, and the works belonging thereto.

Bury, in Lancashire. A Company is about to be formed for establishing Water-works to supply the town.

Falmouth Harbour.—The foundation stone of the Pyramid or Cone to be erected on the Black Rock, between Pendennis and St. Mawe's Castle, at the entrance of the harbour, was to be laid on the 30th ultimo.

Patent Screw Moorings, invented by Mr. Mitchell. The Committee for the improvement of the Port of London ordered six of these Moorings to be inserted into the bed of the river, between the collier tiers of Hanover Hole lower tier, and Mill Hole upper tier. The fourth was screwed into the bed of the river the 14th ultimo, by a curious windlass, and lengthening turn-screw, worked by 40 men.

Weymouth Pier.—The contractor has commenced the operation of driving the piles for forming and lengthening the new Pier.

Woolwich Dock Yard.—The wharf is being extended to a considerable distance into the River Thames, which will add a very large space to the Yard, the whole length of the Docks. The new River Wall fronting the wharf is being formed by first driving two parallel rows of piles, about 15 to 20 feet between, with a stage on the top. The mud and soil of the shore of the River is cleared away, and a solid foundation formed; the wall is then carried up, and faced with ashloring of Ranger's Patent Stone, cast in blocks, and backed up with concrete, about 15 feet thick. The concrete is composed of Thames ballast and ground stone-lime, mixed in small quantities (similar to cement) on the top of the stage, and as it is mixed, it is shovelled into its situation. The blocks for the ashlering are 9 and 15 inches thick, and 3ft. by 1ft. 6in. on the face; they are cast in moulds, and made of concrete. The face next the River is finished with a smooth and hard surface, as if it were polished. After the blocks are cast, they are spread over the wharf, and have to remain for some months to harden before they are allowed to be used. The top of the wall is capped with blocks of granite.

NEW CHURCHES.

[*We shall feel particularly obliged to Architects in the Country, to forward us the particulars of any New Churches that are building, the Number of Sittings, Dimensions on the Plan; if with Galleries, Vaults, Tower, Turret, or Spire; Brick or Stone Building: Architect's Name, and the Cost or Estimate; also similar information of any Public Buildings that are progressing.*]

A new Church has just commenced in Bunhill Row; the style is Gothic, with a tower and spire, built of brick, with stone dressings; there are vaults and galleries. Dimensions on the plan, 96 by 60 feet; accommodation for 1,000 to 1,100 sittings. J. H. Good, Jun., Esq., is the architect, and Messrs. Ward the contractors. The amount of tender does not exceed £4,100.

The new Church building in Pemberton Row, in the Parish of St. Bride's, Fleet Street, is a brick building, of a peculiar form, adapted to the site of ground on which it is building. There are to be two tiers of galleries, and a tower. Benjamin Shaw, Esq., is the architect, and Messrs. Hayward and Nixon are the contractors. Amount of tender £2,800

A new Church is to be built at Greenwich. Mr. Wild is appointed the architect.

Bishop Ryder's Church, at Birmingham; the first stone was laid August 10th. It will contain 1,574 sittings.

Fullwood, York, the first stone for a new Church was laid August 10th.

Trinity Church, Ettingshall, Staffordshire, was consecrated on the 23rd August.—The Church, School, and Parsonage, were erected from designs by Mr. Robert Ebbles of Trysull, near Wolverhampton. The Church contains 920 sittings, the whole of which are free, except four pews

Brereton new Church was consecrated on the 21st August.

Walsall Wood New Church—the Church, School, and Parsonage form three sides of a quadrangle, and have a peculiar and picturesque effect, being built over the mines; they are constructed in timber, braced and framed together as firm as a ship, painted black and white, in the style of the buildings of Henry VIII. and Elizabeth.

Priors Lee Chapel, Salop, having become greatly dilapidated, and the population of the neighbourhood much increased, the old edifice was taken down and a new one built, in a plain Gothic style; was consecrated on the 24th August.

Coleham, Shrewsbury. A new Church was consecrated here on the 25th August; the accommodation is for 812 persons. The building is of plain brick, with tower rising above principal entrance; interior measure 60 feet by 46, with elliptical recess for chancel. Estimate £1,835.

Bridgewater Church, erected by the munificence of Lady Bridgewater, at Whitchurch, Salop, and consecrated on the 30th August. A chaste and elegant structure; the principal front is of three divisions, faced with Grinshill stone. The portico is composed of two Ionic columns, and two antæ, surmounted by an entablature. Accommodation for 700 persons.

Falmouth. A new Chapel of Ease is here contemplated.

At Ash, in the Parish of Whitchurch, a new Church was consecrated on the 31st August. Accommodation for 300, which, with the Parsonage, was erected by subscription.—*Gentleman's Mag.*

New Church at Alveston, near Stratford-on-Avon, is about to be built, under the direction of W. Walker, Esq., Architect, of Stratford. The tenders were to be delivered on the 1st instant.

New Church at Downall Green, two miles from Ashton, in Lancashire; the first stone was laid on the 9th ultimo, by Lord Stanley.

Runcorn New Church. This spacious Church is fast progressing towards completion, and when finished, it will certainly be one of the most elegant structures of the kind in this country.—*Chester Gazette.*

New Church at Alstone, in the Parish of Cheltenham; the first stone has just been laid.

New Church at Blackburn, Lancaster; first stone recently laid.

New Church at O'Meath, in the County of Carlingford, Ireland; the first stone was laid last month.

Glasgow Cathedral. The magnificent plans for the restoration and improvement of this Cathedral, which have been submitted to the Town Council by Mr. Gillespie Graham, were highly approved of, and nothing is now wanting but the pecuniary assistance of Government.

North London Cemetery.—The grounds of this Cemetery, in point of situation and soil, is decidedly the best that could be chosen for such a purpose near London; it is situate on the high ground immediately adjoining the beautiful Gothic Church, designed by Lewis Vulliamy, Esq., at Highgate. Considerable progress has been made in laying out the grounds, building catacombs, and the boundary wall. A Chapel in the Gothic style is about to be built at the lower entrance to the grounds. Stephen Geary, Esq., is the architect.

Exeter New Cemetery was consecrated on the 24th August last.

Banbury.—A Catholic Church is now in progress, in the Gothic style, under the directions of Mr. Derick, of Oxford.

Australia.—On the 10th May last, the foundation stone was relaid of the Cathedral Church of St. Andrew, to be rebuilt on a site of ground in a different part of the town of Sydney, in consequence of the original situation proving inconvenient, through the changes which have taken place in the direction of the streets.

BUILDINGS AND PUBLIC IMPROVEMENTS.

Globe Insurance Office, Cornhill.—The architecture of the new building is now beginning to be developed; it is of the Italian style, and will form a very leading feature in the architecture of the city improvements, in the neighbourhood of the Bank. Philip Hardwick, Esq., is the architect.

Law and General Insurance Office.—A new building is being erected in Fleet-street for this Office; the front is of Portland-stone, in the Italian style, with Doric columns on the ground-floor. Thos. Hopper, Esq., is the architect.

Marine Insurance Office.—A building in Cornhill is being altered for this Office, with a new front; the lower part is supported by Ionic columns, and the upper part is composed of large windows in three compartments, with Corinthian columns supporting an entablature on each story. John Davies, Esq., is the architect.

Royal Institution, Albemarle-street. A façade of three-quarter Corinthian columns, surmounted with an entablature, is being added to the old front of this building. Lewis Vulliamy, Esq., is the architect.

A Jews Synagogue, in St. Helen's-place, is being built under the direction of John Davies, Esq.

Bath.—The Victoria Column and Fountain, which forms a very elegant and classic ornament to the entrance of the Victoria Park, are now nearly completed, and more than realize the expectation of all who saw and approved of them when in design only.—*Bath Gazette.*

Sir Walter Scott.—The foundation stone of the Monument, to commemorate the genius and virtue of the late Sir Walter Scott, was laid by the Lord Provost, in St. George's-square, Glasgow.

A splendid Monument is to be erected in St. Andrew's Church-yard, Plymouth, in honour of the late J. Northcote, R.A., being the birth-place of this celebrated painter.

A Monument is to be erected at Norwich, in memory of the late venerable Bishop of Norwich.

A new Receiving House for the Humane Society, in Hyde Park, is being extended, under the direction of J. B. Bunning, Esq.

Serjeant's Inn.—The new buildings are rapidly progressing under the direction of Sir Robert Smirke. One of the clauses in the contract require that all the joiners' work, as well as timber of the basement story, shall be *Kyanised*, and that the plates and all other timbers which are usually let into the brickwork are supported by projecting iron plates or shoes.

Fitzwilliam Museum.—The tenders for erecting the carcase of this building were delivered in on the 10th ult. Messrs. Bakers' tender was accepted. Amount near £36,000.

The anticipated increase of price on iron, which we announced through our correspondent a short time since, has been realized, as an advance on bars of sixty-seven per cent. is now quoted, and corresponding terms on that of pigs. But this is even only nominal, as the iron-masters will not receive any orders but what are subject to the terms at which it may be sold when shipments are made, which from their heavy demands they will not submit to any period but what is discretionary with themselves.—*Western Times.*

MISCELLANEA.

A new Description of Pump, invented by Col. Dandelin, and manufactured by Tonnar, at Namur, for raising water for the citadel of Dinant to a heigth of 300 feet, has been tried at Sambre, with complete success: only two men are required to work the Pump.

Improvement in House Painting.—A very simple method has lately been adopted to render the surface of paint perfectly smooth, and to entirely eradicate the brush marks; it is done by means of a small roller covered with cloth or felt, about 8 inches long and 2 inches diameter, worked in an iron frame on pivots, similar to the common garden-roller. The flatting coat by this method is made beautifully even, and looks exceedingly well.

GRECIAN ARCHITECTURE.—A lecture on Grecian Architecture was delivered on Thursday Evening last, before the Members of the *Tunbridge Scientific Society*, by Mr. W. J. SHORT.

The lecturer, after explaining the various speculations as to its origin, minutely described its peculiar character and beauties, illustrating the subject by numerous large drawings of the various Grecian temples.—He also critically examined the practice of the Architects of the present day in applying the Grecian orders to modern street buildings, and pointed out that the frontages of single houses are too limited for the proper exhibition of classical architecture.

One plan which he proposed to remedy this defect exhibits some novelty.

This plan is to have in all new streets *at intervals* long squares, and in such squares to have what he calls double-shops—that is, shops on the first story as well as on the ground story; thus, by having two shops, and two distinct dwellings in one building, with only one front to ornament, more effect could be obtained at the expense required only to decorate plainly two fronts.

In this design the lower shops would project and form a promenade to the upper ones, which might be shaded and protected from the weather by rows of columns, which would give a bold architectural elevation to these long squares; and by combining a number of houses together in this manner in one uniform whole, the comparison between them and our public buildings would not be so great as at present.

By dividing the population, ladies would be able to walk these upper streets or promenades and enjoy exercise and air, without being annoyed by the lower class, porters carrying loads, and other nuisances—more particularly as the upper shops would suit the light fancy trade, such as Milliners, Jewellers, &c.

As some trades, such as Linendrapers, require more room to show their goods than others, here they might have a lower and an upper shop: this circumstance, of being able to accommodate a large or small establishment, is in favour of this plan, as it would do away with the necessity of breaking the uniformity of street buildings.

At the end of these long squares a light arch might be thrown across from the upper promenade on one side to that on the opposite side, so that any person could go from one side to the other without descending into the lower street again.

These arches would have the effect of breaking the long lines of buildings, at the same time leaving enough to be seen to raise the anticipation of the stranger, from which he would be able on ascending them to obtain a new and varied view of the whole scene.—*Maidstone Gazette*, October 3rd, 1837.

Brick and Cement Beams.—A fresh series of experiments have been trying lately at the Royal Engineers Establishment, Chatham, by authority from the Board of Ordnance. Three experimental brick beams, each resting on piers of brick, were constructed and broken by weights, which were applied over the centre of each. The piers were 2 feet 6 inches high and 18 inches square. The beams were 10 feet long, of the same width as the piers, and 1 foot thick. No. 1 beam was built of pure cement. No. 2 was also built of pure cement, with the addition of five longitudinal pieces of hoop-iron, one of which was in the centre joint, and two others in each of the remaining joints. No. 3 was built with mortar, composed of three parts clean sharp sand, and one part of Halling lime, and had also hoop-iron in the joints. The wood work for supporting Nos. 1 and 2 was removed in nine days, and that for supporting No. 3, in six weeks after they were finished. No. 1 beam was broken down, but it yielded sooner than it was expected; but it proved that for buildings where beams are usually used it may be safely applied. No. 2 also was a satisfactory experiment. No. 3 was tried on Saturday. The object of the experiment was to ascertain the use of cement-bond in the walls of buildings, as a substitute for bond and chain timbers; and also for ascertaining what additional strength is added to the bond by using hoop-iron in the joints. Mr. Brunel first tried some very interesting experiments, proving the extraordinary strength of brickwork laid in pure cement, with hoop-iron in the lower joints, but the same thing had not been tried without hoop-iron, which led to the experiments under Colonel Pasley.

No. 1 beam was broken with a weight of 208lbs.; the break was not in the centre, but extended in two vertical seams, the one about 6 inches, the other 18 from the centre.

The strength was in favour of the cement, for in no direction did it give way; but, on the other hand, the bricks were rent with an even fracture.

Another experiment was then made with the largest piece remaining, which measured about 4 feet over the piers: this required a weight of 2356lbs., and the fracture was similar to the former.

No. 2 beam was tried on the next day, and was found capable of supporting 4723lbs., but gave way on the addition of 56lbs. ∴ 4723—498 (weight required without the longitudinal bonds) = 4225, the amount of strength gained by the use of iron bonds.

No. 3 gave way with a pressure of between 400 and 500lbs. There was nothing remarkable in this experiment.

The above experiments were necessarily imperfect, the power not being applied as it would be in practice; for it is evident, that with a wall of from 10 to 15, or even 20 feet of solid work, the pressure, instead of acting merely on the centre, would be diffused throughout the whole beam. Upon clearing away the bricks from the middle of No. 2 beam, the two lower bars were found drawn asunder, the middle one remained of the same length, and the upper pair found, what is called buckled, or folded on themselves, showing the neutral centre to be in the middle bar.

We may take this opportunity to observe, that the foundations of the new Judges' Chambers, in Chancery Lane, are being constructed after the manner of the beam No. 2, having a length of hoop-iron to every row of bricks, and bedded in Roman cement.

On 14th ult., some further experiments were made by Colonel Pasley at Chatham, in the presence of the heads of the Naval and Military Departments there, and many scientific gentlemen, upon the strength of cement. The first experiment was to ascertain whether a safe staircase might be made with artificial stones formed with bricks and tiles, or other small materials united with pure cement, strengthened by hoop-iron bond.

A portion of the brick beam used in No. 2 experiment, in length 4 feet 4 inches, was inserted 9 inches into the wall of a stable; it consisted of four courses (two more than is used in a geometrical staircase); the extreme end of this step had no support whatever, so that we had the novel exhibition of a horizontal column of brick retained together by cement and iron bars. Being loaded, it sustained the weight of 3606 lbs. Beneath the extreme end of the beam was placed a block to break the fall; when the weights were removed, and the block withdrawn the column remained at the angle at which it fell, and required great purchase to remove it finally from the wall. Not one of the iron bars had given way.

The second experiment was for the purpose of ascertaining the force with which the hoop-iron strengthened the brick beams, by weights acting on a piece of hoop in a state of tension. In this case a piece of hoop-iron, 12 inches long, similar to that used in the above experiment, sustained a weight of 6163 lbs., then yielded with a fair fracture; it was elongated $\frac{7}{8}$ of an inch, and its temperature sensibly increased.

The third experiment was upon the remaining portion of the brick beam, built with Halling lime mortar, and strengthened with hoop-iron, which was broken on the 28th ult., but one end of which was little injured. This beam was placed across two piers two feet asunder, so that the bars had very little room for extension; the experiment, however, was remarkable, for the beam sustained the weight of 4887 lbs. It did not give way suddenly; two bricks fell from the lower course many minutes before the final crash, and this did not occur until it had been yielding with a slow, gradual motion. The fall was so tremendous that one of the piers were overturned, and scarcely two bricks were found together. So much for mortar. None of the bars were broken in this experiment.

It appeared in these experiments that the iron was corroded in the mortar, but not in the cement, another security of the latter over the former.—*Mechanics Mag.*

Rotatory Steam-Engine—Mr. Ruthven has now got the rotatory engine upon Avery's principle erected, and we saw it in motion on Wednesday. Having described it before, we shall merely observe at present, that it moves by the re-action of high pressure steam, which rushes through two small orifices at the opposite sides of two hollow arms, and impels them in a circular direction with incredible velocity. The engine has neither piston, cylinder, beam, crank, nor valve. The arms are of two feet six inches radius, and as they perform about 3,000 revolutions in a minute, their extremities must move at the rate of a mile in eight seconds. This very high velocity, or something approaching to it, is essential to the working of the engine. No noise is heard when it is in motion, but only a low humming sound like that of a boiling kettle. The trial on Wednesday was merely to show its mode of operating, but it is soon to be employed in some heavy work which will test its powers, and we shall then speak of it more at large. If its capabilities correspond to the inventor's description, it will deserve to be considered one of the happiest applications of steam power which has ever been given to the world.—*Scotsman.*

New Mines of Coal have recently been discovered at Hanarechang and at Bidgegur, in the south eastern corner of the Mirzapore district, said to be superior to the coal of Burdwan. This discovery will probably form an important era in the history of steam navigation in India.

Coal Mines in the Isle of Man.—These mines are about to be worked by a company with a capital of 6,000*l.*, which they assume to be sufficient for that purpose.—*Cumberland Pacquet.*

The Iron Trade.—Never were the prospects of this trade more cheering than at present. Orders are daily flowing in, and the price of the metal is consequently on the increase. We have it from good authority that 9*l.* per ton has been refused by some of the large masters for bar iron.—*Monmouthshire Merlin.*

Large cargoes of iron are now weekly exported from Ulverston to Antwerp. This may appear singular to those who know of the richness in this mineral with which the Netherlands abound; but it ought to be more generally known, that the finest iron in the world is that produced from the ore of our neighbourhood.—*Kendal Mercury.*

TO CORRESPONDENTS.

WE thank our numerous Correspondents for their suggestions—we request of them patience, and if it be possible to meet with their wishes we will do so. We have met the suggestions of several Correspondents, and so arranged the work, that the last page of No. 1. may be cancelled when the volume is completed, and bound up;—we will make a similar arrangement in future Numbers, so as to prevent the Advertisements appearing in the work when bound. In the present Number we have added two additional pages of matter, and a wrapper: if we are supported by a liberal supply of Advertisements to pay for the additional expense, we will continue this arrangement.

We regret that we have been obliged to disappoint several Subscribers in the Country, in consequence of the Stamped Edition not being allowed to pass the Post Office: we will endeavour to remedy this evil, if possible, before our next Number is published.

BOOKS RECEIVED.—Examples of Gothic Architecture, by P. L. Walker; 2 Parts large paper, with plates.—Music of the Eye, or Essay on the Vitruvian Analysis of Architecture; by Peter Legh, Esq., M.A.—Essay on the Construction of Ships and Vessels, and an Account of H. Barbe and Stuard's Patent. This Patent has expired too long for us now to notice it; besides, it would lead us into an endless controversy on the subject.—Artificer's Lexicon, by John Bennett.—Samuel Hall's Address to the British Association.—Complete Book of Trades, by Bennett and others; 8vo. plates. A useful work for children.

BOOKS received, which will be reviewed in our next Number.—Sundry Pamphlets on Kyan's Patent.—Warming and Ventilation of Buildings, by C. J. Richardson, Architect.

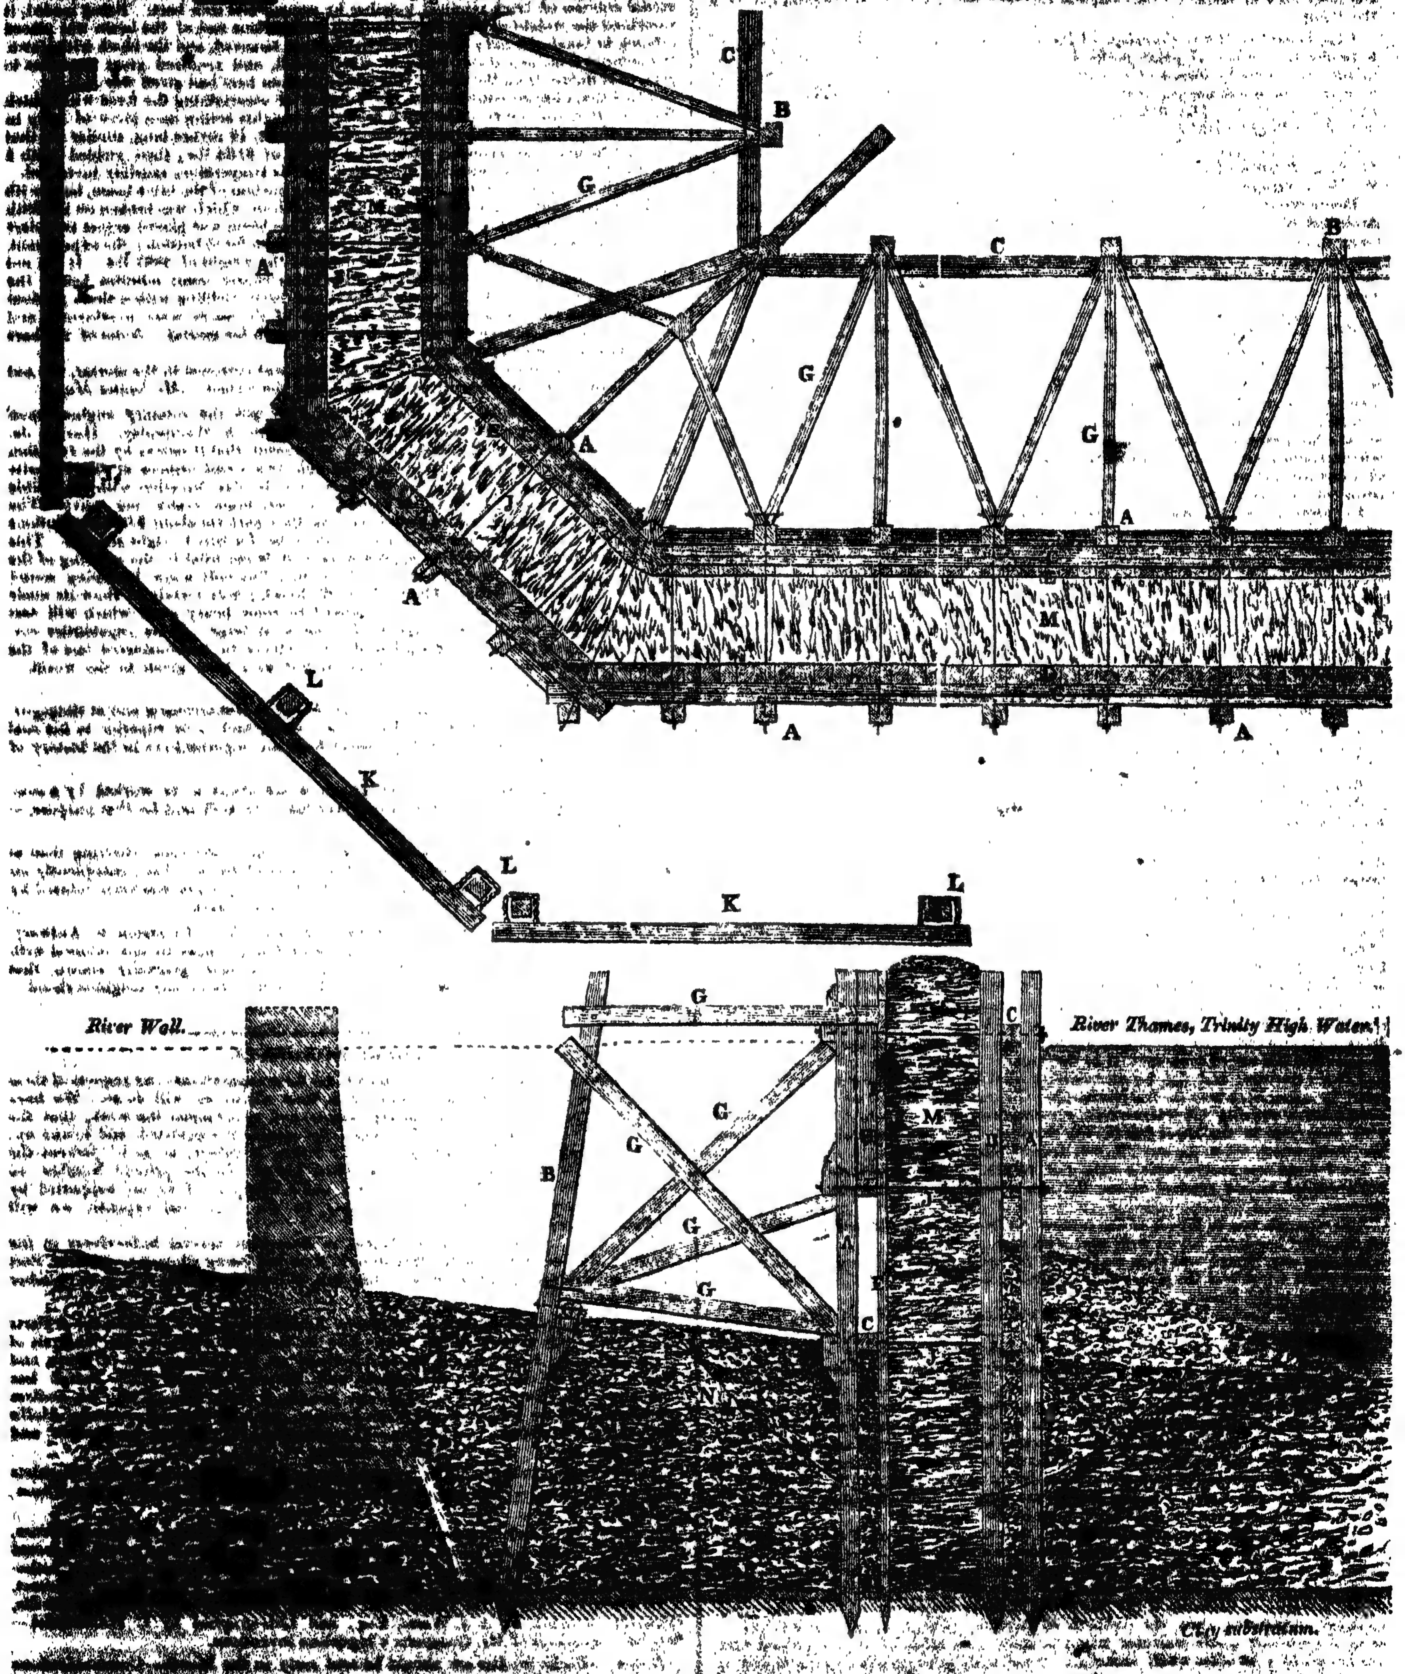
Engravings and Lithographic Drawings received.—Restoration of the Roman Forum, drawn by S. Walker, Architect, of Nottingham.—Lithographic View of the Projected Improvements in Westminster, designed by Wm. Bardwell, Architect.—A Lithographic View of the Cathedral Church at Wells, drawn by P. L. Walker, Architect. A Lithographic View of the Isle of Man Building Company's new town, Woodville, spiritedly sketched by A. J. Watts, Esq., and Lithographed by C. Hullmandel.—Several Engravings of Mr. Gompertz's ingenious inventions.

Notices.—Books for Review should be sent early in the Month—Communications on or before the 20th—and Advertisements on or before the 25th Instant.

HOUSES OF PARLIAMENT.

(For General Description and Plan, showing the extent of the Works, refer to page 12, No. 1, Journal.)

Figs. 1 and 2.—PLAN AND SECTION OF THE COFFER DAM.



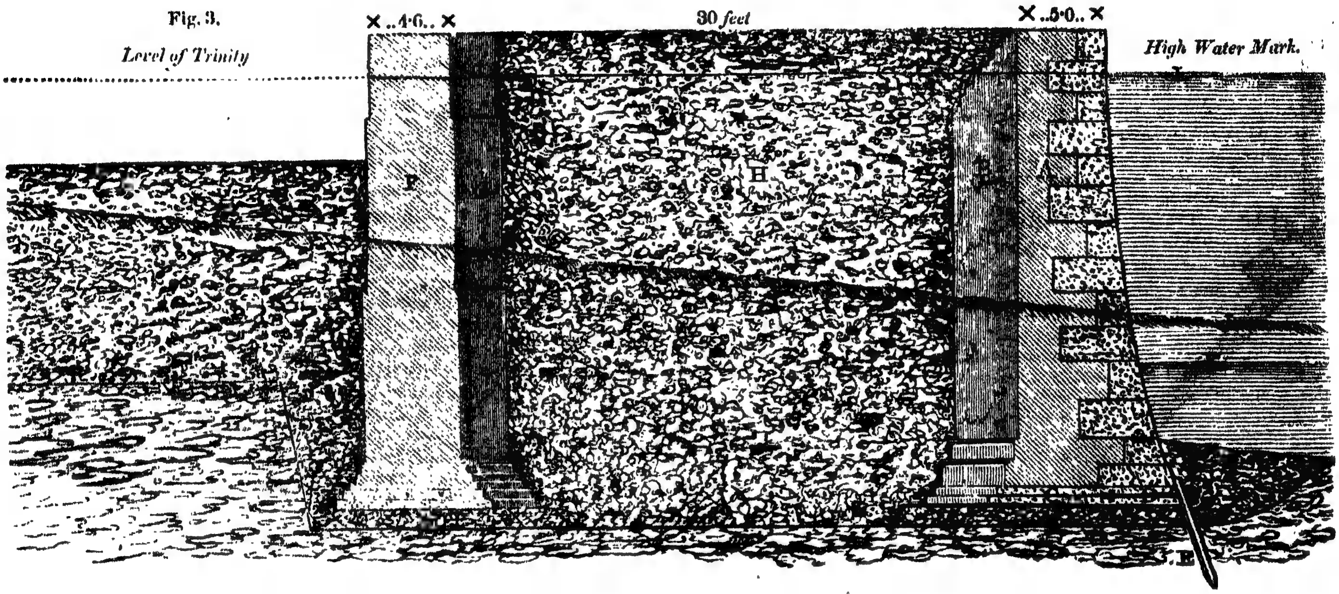
DESCRIPTION OF THE COFFER-DAM.

Fig. 1 is the plan of the coffer-dam, and Fig. 2 the section; the letters in both figures refer to the same descriptions.

A A Main Piles, } not less than 12 inches square.
B Brace Piles,
C Wales,
D Sheet piling to outer row, not less than 12 inches thick.
E Ditto to inner row, not less than 6 inches thick.
F Planking top of ditto, ditto.
G Braces and ties, 12×6 inches.
H Furring.
J Iron ties or bolts, 2 inches diameter.
K Booms, } 12×12 inches.
L Fender piles,
M Puddle, 5 feet wide in clear of the piles, of good stiff clay. The bottom of the river above the line N is to be dredged. The slope against the piling is to be formed as directed in specification. The bed of the river is gravel, and the substratum clay, into which the points of the piles are driven 2 feet. The wall indicated in feint lines, is the site of the river wall as shown in the figure below, marked A.

SECTION OF RIVER WALL, FRONT FOUNDATION WALL, AND CONCRETE BACKING.

Fig. 3.



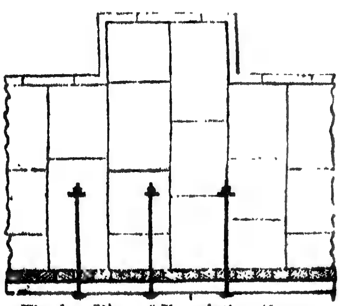


Fig. 4.—Plan of Foundation Course.

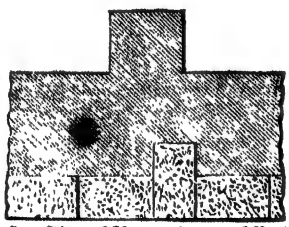

Fig. 5.—Plan of Upper Course of Footing.

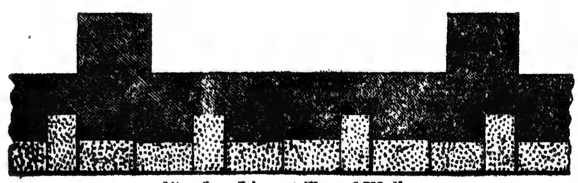

Fig. 6. —Plan at Top of Wall.

DESCRIPTON OF THE ABOVE.

Fig. 3 is a section of the terrace, marked c in the general plan, showing the river wall and front wall of the building, also the concrete foundation.

A is the river wall faced with granite, as described in the specification, 7 ft. 6 in. thick above the footings, and 5 ft. thick at the top: the two lower courses above the stone landings are 1 ft. 3 in. high; 3rd course, 2 ft. 2 in.; 4th and 5th courses, 2 ft. 1 in.; 6th and 7th courses, 1 ft. 11 in.; 8th and 9th courses, 1 ft. 10 in.; 10th and 11th courses, 1 ft. 9 in; 12th and 13th courses, 1 ft. 8 in. high each; and the top course, 1 ft. 8 in. high; total height of the wall above concrete foundation, 28 ft. 6 in.

B counterforts, shown in fig. 5 and 6, projecting 3 ft. 4½ in. from the inner face of wall, and 3 ft. 9 in wide.

C Two courses of 6 in. stone landing for foundation, bedded on 1 ft. thick of concrete; the lower course of stone is 11 ft. wide.

D Iron tie to secure the walling.

E Sheet piling, 8 ft. long and 8 in. thick, to protect the foundation.

F The foundation wall to front of building, 5 ft. 3 in. thick, above the footing, and 4 ft. 6 in. thick at the top, with two courses of stone landing; lower course, 8 ft. 4 in. wide, bedded on 1 ft. of concrete as river wall.

G Counterfort projecting 2 ft. 4 in. from the face of wall.

H Concrete backing; the whole space between the river wall and front foundation wall is to be filled in solid with concrete 30 ft. in clear of the walls, and 26 ft. 9 in. high, forming the terrace marked c, in the general plan.

JJ is a line showing the present surface of the bed of the river.

K Low water mark.

L High water, Trinity standard.

M Concrete foundation 12 ft. thick over the whole site marked B in the general plan; the top of the concrete is 4 ft. 6 in. below the high water Trinity standard; a similar foundation of concrete, 20 ft. thick, is to be made over the whole site marked A A in the general plan.

Fig. 4. Plan showing the foundation course of 6 in. stone landings, and the iron ties 4 ft. apart, to secure the wale and sheet piling.

Fig. 5. Plan of the upper course of footing, showing the stone-work and one counterfort.

Fig. 6. Plan at the top of the river wall 5 ft. thick, showing the stone facing, and two counterforts which are 10 ft. apart from centre to centre.

(Scale of Drawings, 10 ft. to one inch.)

SPECIFICATION OF THE RIVER WALL, AND OTHER WORKS CONNECTED THEREWITH.

Messrs. Walker and Burgess, Civil Engineers.—Charles Barry, Esq., Architect.

COFFER-DAM, &c.—Before the pile driving is begun, a trench is to be dredged in the intended line of the coffer-dam, to the depth of three yards below the level of low water, of 16 feet under the high-water of Trinity standard, and of such width as is necessary to allow the piling of the dam to be got in clear of the side slopes.—The coffer-dam is to be constructed of good and suitable Memel or Dantzic fir timber, of the scantlings and dimensions specified in the drawing.—The guage piles are to be of length sufficient to be driven to the depth shown, or such other depth or depths as may be necessary, so that the points may be at least two feet in the clay.—The wales are to be in two thicknesses, of half-timbers, breaking joint properly, and bolted to the guage piles, except at the returns; the wales on the splay or angle of which are to be of whole timber, in one length, laid over the waling of the sides of the dam, and secured to it by a strap passing round the same, with bolt ends through the wale above, and to be also bolted to the guage piles as before, with a cleat or strut to block out the angle ones.—The sheet piling is to be of whole timber in the outer row, and half timber in the inner row, and is to be driven with a close joint to the depth that has been stated for the main piles, and to be secured to the wales with inch bolts, one to each pile. The inner row of sheet-piling is to come up to the level shown, and the height above is to be made up with horizontal pieces, bedded down on the tops of the sheet piles, which are to be cut off level to receive them, and secured with three-quarter inch bolts to furring pieces inserted above the waling at each guage pile, and strapped thereto. The sheet piles in the angles, at the returns of the dam, are to be splayed on the edges so as to be fair and close with the square edges of the adjoining piles.—The brace piles are to be of the length, and driven, as shown, with a wale of whole timber, to receive the lower ends of the diagonal and raking braces of the dam, which are to be tightened with wedges to the cleats on the backs of the main piles, and stiffened with three-inch planks, spiked on their sides, and also to the brace piles immediately below the tie, to steady the dam at top, and the whole is to be firmly secured with proper straps and inch bolts. The braces to the angles of the returns of the dams are to be of whole timber, as on the drawing, with an additional brace pile behind: strutting pieces are also to be inserted between the points of abuttal of the bracing on the main piles; and such other struts and bracing, as may be necessary in getting in the works, are also to be used.—The outer and inner rows of piling of the dam are to be securely tied together, with two-inch wrought-iron thorough bolts, passing at the heights shown from side to side of the dam, and through the guage piles, with proper washers thereto.—The fender piles are to be driven to the extent shown at each extremity of the dam, and at the distances marked therefrom, and from each other, and are to have floating beams or booms attached to them by chains passing round them, so as to allow the booms to move freely up and down with the flow and ebb of the tide.—All the piles are to be shod with proper wrought-iron shoes, to an approved pattern, those for the whole timber piles weighing 25lbs. each, and for the half timber ones 20lbs. each. The tops of the piles are to be hooped, and all such piling as is not truly and properly driven, and such as is, or is supposed to be split or otherwise injured in driving, is to be immediately taken up and replaced.—When the whole of the piles are driven and properly tied and braced, the space between the rows of close piling is to be cleared out to the clay, and then filled in solid up to the top with good stiff clay, mixed with a portion of gravel, and well worked and pounded in, so as to form a water-tight body, which, as it sinks, is to be made up, and afterwards occasionally rammed when required.—The foot of the piling, both outside and inside the dam, is also to be protected by a mass of proper material from the excavation, laid against it as shown; and where the dam meets the present wharfs at either end, the wall is to be cut through, and the puddle carried into the solid ground as far as may be necessary; the angles being also further protected by proper material laid outside and inside, with dwarf piling, to support the same if necessary.—Three trunks or shoots, consisting of two-feet cast-iron pipe, filled with proper water-tight valves, are to be provided and fixed with joints, also water-tight, in such situations and at such levels as may be judged necessary.

PUMPING.—For pumping and keeping the works clear of water, a low pressure steam-engine of not less than ten-horse power, with proper pumps, pumping apparatus, and other necessary machinery of approved construction, and of power sufficient for the purpose, is to be provided, and erected on a proper foundation or staging, on such part of the dam or ground as shall be pointed out, to be ready for work immediately on the completion of the dam. Proper drains to the engine well are also to be made, as shall be directed, and kept open, so that every part of the foundation may be kept clear of water while getting in.

EXCAVATION.—The excavation for the foundations is to be got out in lengths of 50 feet, and from the river wall to the front wall of the proposed building, including the sites of such walls, is to be carried to a depth of one foot under the lowermost course of footings of the walls, and of such width beyond them as to allow the foundations to be put in clear of the slopes, which, if necessary, to prevent their falling in, are to be supported at foot with piles and planking, or sheet piling, and these are to be removed as the backing of the wall is made up.—And when the excavation has been brought to the required depth, the surface is to be cleared and levelled to receive the concrete hereafter specified.—The whole of the materials, to the depth shown, is also to be removed to the extent showed in the drawing in No. 1, page 12, and carted or barged away, except such part thereof as may be approved as a fit ingredient in the mortar or concrete which may be retained for that purpose; and such portion of the present embankment wall as is included within the said tinted space, and also the waterman's stairs, are to be entirely taken down, and the rubbish cleared away; the materials, except such as may be required for purposes to be specified hereafter, becoming the property of the contractor.

FOUNDATIONS.—The sheet piling of the river wall is to be of the best fresh elm, eight inches thick, sawn all round, and to be shod with wrought-iron shoes, weighing 18lbs. each, and driven with a completely close joint in the most perfect manner, and each pile spiked to the wale, which is to be of sound English or African oak, in long lengths, lapped at the joints, and the whole is to be secured to the wall by means of inch wrought-iron ties, with cast-iron counter-sunk washer outside, passing through the wall, sunk into the stonework between the first and second course of footings, and terminating at an average length of six feet, with a nut screw and washer twelve inches long, six inches wide, and inch thick, let into the stone at a back vertical joint of one of such courses, and run with lead.—The concrete of the foundations of all the walls is to consist of six measures of gravel and sand to one of ground lime, mixed dry, and then well worked together with water, and in this state teemed and thrown into the work from a height of at least ten feet, and is to be brought to a level surface at the proper depth, to receive the first footing course, which is to bed solid upon it.

FOOTING COURSES.—The two footing courses of all, the walls are to be formed throughout of six-inch Yorkshire landings, of good tough quality, in large pieces, with fair beds, squared on the joints so as to lie close, and to be laid in mortar, with the joints properly broken as shown, the face being also bevelled next the sheet piling of the river wall, to suit the inclination of the same.—The two next courses of the river wall are to be faced with the best Bramley-fall, or other stone of equal and approved quality, in courses of the height marked, rough picked on face, and in other respects dressed and laid in the manner hereafter described for the ashlar generally, and of the same proportion of lengths and depths.

ASHLAR FACING.—The ashlar facing of the river wall, and of the return walls of the wings, is to be of blue Aberdeen, or blue Peterhead, or Hern or Dalkey, near Dublin, or the fine grained Dunleary granite, all of the best quality, in the uppermost six courses of the face generally, and in the spandrells of the stairs, as well as in all quoins throughout; and of the best Penryn, Heyton, Dartmoor, Fowey, or Galloway granite, in the rest of the work; and all the granite, of whichever of these descriptions, is to be without black spots, stains, or redness of any kind; and should any two or more of the said kinds be used together, it is to be perfectly understood, that uniformity of colour, and similarity of quality, are indispensable. The stones are to be fine axed on the face, to the true curve of the walls, so as to present a fair and perfect surface, at least equal to a sample which will be shown to intending contractors. The specimen stone will be shown by the porter at the door of the Speaker's house. The beds and joints are to be full and square for their whole depths (particular care being taken to preserve the outer arises), so that when set, the work may be close and solid throughout, without any packing, and no joint exceeding an eighth of an inch in thickness. The backs are to be scappled with a prick, square to the beds, and with a fair surface, to receive the brickwork.—The courses are to be of the heights figured, and to be laid with one header to every two stretchers. The heading stones are not to be less in length of face than the height of the courses of which they are to form part, nor less, in depth of top bed, than double the height of the said courses; the stretchers are not to be less, in length of face, than twice the height of the courses wherein they are to be inserted, nor less, in depth at top, than the height of the said courses, and the bond in the vertical joints is not to be in any case less than one-half of the height of the course immediately below them.—The stonework is to be laid throughout on a thick bed of mortar, proposed as hereafter directed, the front joints being pointed with cement, and then grouted full; and all the stones are to be worked on the ground, and set with lewises, and proper tackling.

BRICKWORK.—The back part of the river wall and returns, and the counterforts, the whole of the front wall of the building, including the octagonal turrets therein, and the returns of the wings and stair walls, and also the arch under the steps from the foundation upwards, and

other work shown on the drawings, are to be of brickwork, consisting of sound, hard, and well-burned square stocks, laid closely and well bonded, the joints being broken in a careful manner, and not exceeding a quarter of an inch in thickness, every course flushed up solid with thin mortar, and the filling-in bricks rubbed in so as to make each joint flush and full of mortar, and the whole is to be level at the top of every course of the facing ashlar. The arching for the support of the stairs is to be, as shown, springing from cut skew backs, and properly keyed in, the whole being flushed in solid after the arch is turned, and the bricks in the angles of the splayed work are to be neatly cut.

Backing and Filling-in.—The space between the river wall and the front wall of the building is to be brought up to the level of the top of the wall with concrete, composed of ten measures, of gravel and sand, to one of unslacked lime, washed in with water, and levelled in regular and thin courses as the work proceeds.—The remaining portion of the space shown on the general plan (in No. 1) and sections, the part under the stairs, and the hearting of the hollow octagonal turrets, are to be made up to the levels shown with concrete, same as has been described for the foundations of the walls, and used in like manner.—The space excavated in front of the river walls to get in the foundations thereof is to be made up to the level shown on the section, and cut to the brace piles of the dam, with pieces or burrs of the present embankment wall, laid at the foot of the proposed wall, and well grouted with concrete, same as the backing thereof.

Mortar and Concrete.—The mortar throughout is to be composed of one measure of the best fresh burned Merstram, Dorking, or other equal and approved lime, one measure of finely-ground genuine Italian pozzuoland, and two measures of sharp above-bridge river sand, all clean and free from rubbish, dirt, and other impurities. The proportions are to be correctly ascertained, after which the lime, which is to be brought from the kiln in small quantities as required, and kept dry under cover, is to be slaked and mixed with the pozzuoland and sand; they are then to be passed together in the dry state through screens, the water added, the mortar well tempered and worked to a tough and proper consistency, in horse or pug-mills for the work generally, but for the stonework, ground with edge stones, worked either by horses or by means of gear attached to the steam-engine for pumping the water out of the dam.—Fresh burned lime of the above description, and clean coarse river gravel, having mixed with it a proper quantity of sharp sand, are also to be used in the proportions stated in making the concrete that has been specified for the foundation of the walls and the backing.

REVIEWS.

Prolusiones Architectonicæ; or, Essays on Subjects connected with Grecian and Roman Architecture. By William Wilkins, A.M., R.A., F.R.S., Regius Professor of Architecture in the Royal Academy. 4to. Part 1. with 17 Plates. London, John Weale, 1837.

Although Mr. Gwilt has taken an opportunity in his "Elements" of sneering at the choice shown by the Royal Academy in electing Mr. Wilkins to the chair of architecture, as far as scholarship can be any qualification for that professorship, we know of no one in the profession who could have been opposed to him with equal pretensions. Even had he written nothing else, the present volume would fully make good his title to erudition, which, to say the truth, predominates in it to such a degree, that it will be quite a sealed book to the many, and must content itself with "audience fit, though few." Had its author wished for a motto to it, hardly could he have found a more appropriate one than the inscription over the entrance to the ante-room of the Academy's old apartments of Somerset House: Ουδεις Αμουσος Εισιτω. In the philology of the art it is *plus Arabe que l'Arabie même;* so much so, that it would have been more at home in the pages of the Classical Journal, than it can be in our columns; for the author seems to have written quite as much, if not more, for his brother scholars on the banks of Cam, than for his brother architects on those of Thames; especially in these degenerate days, when the folios of Stuart are stewed down, after portable soup fashion, and reduced to the tiny dimensions of a waistcoat pocket-volume. Still the volume is likely to be extensively purchased for the very reasons that will hinder it from being generally read.

Of the dissertations contained in it, we shall take the liberty of passing by those relative to the Erechtheum, the one on the Athenian inscription, with that upon the construction of roofs of temples; and confine ourselves to the last one, entitled "The Temple of Jerusalem, the Type of Grecian Architecture," as best suiting our purpose, and as likely to be most generally interesting. We may, however, remark *en passant*, that contrary to nearly all other writers, who call the tetrastyle portico of the triple temple on the Acropolis that of Minerva Polias, Mr. Wilkins gives that name to the hexastyle one at the East end, but, unless we have overlooked it, without assigning any reason for the change he has made.

We now proceed to consider the author's hypothesis on the subject of the Jewish, or as he terms it, Syrian temple; and hardly could he have selected one that admits of greater latitude of interpretation, or affords wider scope to fancy. It has accordingly been a favourite one with numerous writers who have exercised their ingenuity upon it, some of them till they have quite bewildered themselves and perplexed their readers. "Few things," observes Mr. Hosking, "have occasioned controversies more amusing, from the singularity of some assumptions, and the absolute futility of them all, than the style and manner in which Solomon's Temple was built." Thus the learned Spanish Jesuit Villalpanda insisted, among other things, that what we term the Corinthian order, had been employed in that edifice ages before the supposed invention of it. Mr. Wilkins now comes forward in his turn with a theory somewhat akin to that of the Spaniard, his object being to convince us that the Jewish edifice was the immediate prototype of the larger Doric temple at Pæstum, which agrees with it in all its admeasurements, as he shows by his plates of the two edifices. Still we cannot help thinking that he lays too much stress upon an agreement between them of that kind, which might be altogether accidental; while he treats as so unimportant as not to deserve notice, even those differences of plan which even his own drawings make manifest, and which, supposing him to be perfectly correct in all he assumes, must have produced a strongly marked difference of character. For instance, however exactly they might agree to size, there must surely have been considerable architectural disparity between an edifice enclosed on its sides and one end by a series of chambers, and having a porch in front *narrower* than the body of the building, and one that is peripteral, or entirely surrounded by columns. Were dissimilarity to stop short even here, there would be a sufficient degree of it to counterbalance that of the coincidence upon which, as it appears to us, Mr. Wilkins builds up the whole of his hypothesis; because as to the resemblance he is pleased to make out between the two structures, in the comparative elevation he gives of them, that is entirely conjectural, with nothing to corroborate it, should there be nothing positively to contradict it. So far, however, from this being the case, there is one circumstance overlooked by him, whether intentionally or not we pretend not to judge, that is fatally adverse to his argument and his elevations. In the First Book of Kings no mention is made of the height of the porch of the temple; but in the Second Book of Chronicles it is recorded to have been one hundred and twenty cubits, or six times its breadth; consequently it must have been a tower of lofty proportions, rising far above the rest of the edifice—a feature utterly irreconcilable with anything extant in Grecian architecture; while, as Stieglitz has observed, it reminds us at once of the tower-like *propyla*, erected before Egyptian temples. In front of such propyla it was usual to place obelisks, one on either side the entrance, and such we must suppose to have been the situation of the two mystic pillars Jachim and Boaz.

Now, how does Mr. Wilkins dispose of all this? Why, misled, at least so we cannot help thinking, both by his own ingenuity and his eagerness to establish his hypothesis, he cuts down this lofty part of the edifice into a mere distyle in antis porch, crowned by a pediment lower than that of the temple itself; which circumstance alone, of a double pediment, militates, we apprehend, not a little against that similarity between the Jewish and the Grecian temple, which it pleases him to take for granted. *Ce n'est que le premier pas qui coute*, therefore, after his taking such a stride towards his wished-for conclusion, we need not be at all surprised at his converting Jachim and Boaz into two ordinary Doric columns. This is perfectly a gratuitous assumption on his part, there being nothing whatever in the account we have of the building to show that they resembled those of the Doric or any other of the Grecian orders; on the contrary, as they were of "molten brass," the greater probability is that they were cylindrical, and that they were merely symbolic ornaments set up on each side of the entrance, and therefore obtained distinctive appellations, which we conceive they hardly would have in any other case. That they were so placed becomes all the more probable, because we read that the height of each was eighteen cubits, and that of its capital five, an exactness of information that might have been spared had they supported an entablature, since in that case their height must have necessarily been the same. Mr. Wilkins, indeed, contends, that our English translation is erroneous, and that by the term ἐπιθέματα, rendered "chapiters," should be understood the entablature; but then what occasion would there have been to remark that the dimensions were the same in regard to both columns, since difference would have been hardly possible; yet such difference alone would have required to be noticed. Whether Mr. Wilkins is at all borne out in his hypothesis by any one writer who has preceded him, is more than we can undertake to decide; but he certainly is quite at variance with all we have had the opportunity of referring to; among the rest John Wood, of Bath, who in his

"Origin of Building, or the Plagiarism of the Heathens Detected," treats at some length of Solomon's Temple. Most certainly Mr. Wilkins's hypothesis is not at all countenanced by Mr. Bardwell, who, in his chapter on Solomon's Temple, tells us that "it had not in proportions and details anything in common with the temples of Greece." In fact, although we have no means of judging from such partial, vague, and indefinite description as the Sacred Writings have handed down to us, how far the edifice resembled in details and style those of Egyptian architecture, there is enough to convince us, that in its interior ornaments and carvings it must have been utterly unlike anything we are acquainted with in Grecian architecture. The tall capitals assigned to the two columns of the porch warrant the supposition that they, and the columns themselves, partook largely of the Egyptian character; while, again, the extensive courts surrounding and enclosing the temple, and the loftiness of the porch, strikingly accord with the practice of the Egyptians. We leave it to those who have a taste for such fanciful speculations, to trace back the modern church tower or steeple to the porch of the Jewish temple, or the *propyla* of Egyptian ones.

How far it would be in Mr. Wilkins's power to continue and complete the parallel he has begun we know not, since he has not even touched upon this portion of it. After all, although we cannot bring ourselves to agree with his views of this particular subject, we readily bear our testimony to the value of his work, were it only on account of the light it throws upon much that is connected with the technical practice of the ancients, and the terms employed by them.

Le Keux's Memorials of Cambridge, &c., &c., with Historical and Descriptive Accounts of the Buildings. By Thomas Wright, M.A., *&c.* No. I.

The close similarity of plan between this work and the Memorials of Oxford renders it unnecessary for us to say anything in regard to the mode in which it is got up, or the execution of the views; for it may fairly be considered as another series of what will eventually form a single work, although either portion will be complete in itself. That the present series will be quite equal to the former one we make no doubt, and still more certain are we, that with a little attention it might be made to exhibit a decided improvement upon the "Oxford," without at all affecting uniformity of plan.

Instead, therefore, of flattering the parties engaged on the Memorials of "Cambridge," by assuring them they cannot do better than adhere in every respect to the system pursued in those of "Oxford," we prefer plainly telling them what we consider the defects of the latter; which we take this to be the more friendly mode of the two, because we shall be all in good time with our advice: it depends upon them to take it in good part, and avail themselves of it, though, after all, it is more likely that they will stick to their old course. Now, as concerns the illustrations of that university, it occasioned us no little dissatisfaction and disappointment to find that so large a proportion of the subjects are comparatively insignificant and devoid of interest, there being several views of churches which have not the slightest architectural value, and which can hardly be said to belong properly to the work. Had they been absolutely necessary in order to eke out another volume beyond the two to which the publication was originally limited, there might have been some excuse for resorting to them as a *pis aller*. So far, however, from this being the case, while they have been thus dragged in for the nonce, many very interesting parts, both of the colleges themselves, and of other public buildings, are not shown at all. With regard to their interiors matters stand even worse, since of such subjects there is but a very small sprinkling indeed, and that consists not so much of collegiate edifices as of churches. In fact, so very far is that or any other work of the kind we have yet met with from having gleaned the field quite bare, that an artist of any intelligence and taste would discover for his pencil as many, or even a greater number of perfectly fresh and untouched subjects than of those already handled. We are further of opinion that it would have been an essentially serviceable feature in the work, had there been a general ichnography or block plan of each college, showing the disposition of its buildings, courts, &c., which would have afforded a far clearer idea of its extent and locality than can be conveyed by a page of description. Such plans might have been given without incurring additional expense for woodcuts, because many of the present ones—those of seals and similar 'curiosities'—could very well have been spared in order to make room for what would have been so much more instructive.

As we have stated, we have not the slightest expectation that our advice will be taken, otherwise than in dudgeon. Nevertheless, although foreseeing that such is likely to be the event, we cannot help tacking to it another piece of admonition, which is, that fresher points of view should be selected than we perceive has been for the "Library" and "Great Court" of Trinity College, in the first number of the "Cambridge." For want of due attention to this, drawings "made expressly for the work" are apt to look too much like copies from other publications. Topographical collectors—and we presume the work looks to that class of purchasers for some patronage—feel the consequences of this very sensibly, for they get precisely the same subjects over and over again; the only difference between old acquaintances and the new-comers being that the latter may be better-looking. Let this be reformed. It would not, indeed, in every instance, be so easy to select a new point of view quite so good as those already made use of; but there are also many cases where it would not be difficult to make choice of one far better. Besides, even where there is hardly any alternative than taking a view of a building in the same *direction* as has been repeatedly done before, there is no necessity to take it likewise from the same *distance*, and make the subject the same composition. It would frequently be very much better to bring the building nearer than is usually done, so as to describe its architectural character more exactly, and to dwell upon the expression of its details more *con amore*. One other piece of advice and we have done for the present, though, as we shall keep our eye upon the work during its progress, we shall perhaps occasionally make our report to our readers. What we lastly recommend is, that as the letter-press is evidently got up to accompany the plates, and not *vice versa*, there should be much more of architectural description than we meet with in the "Oxford," which is in that respect exceedingly jejune and unsatisfactory.

Notes Abroad, and Rhapsodies at Home. By a Veteran Traveller. 2 Vols. London, 1837.

Most undoubtedly, this work is not exactly one of those which we profess to take cognizance of; still it contains so much upon the subject of architecture, that we are fully warranted in so far considering it as belonging to our jurisdiction. On the other hand, we hardly need regret that we are relieved from the duty of passing any formal opinion on the rest of its contents; because, to say the truth, there is a good deal in it likely to give offence to the thin-skinned, which may be one reason why the reviewers seem so very shy of touching it. All, therefore, that we shall say in regard to these two volumes generally is, that our "Veteran" seems to be of the same family as the "Old Traveller," whose "Vagaries" are in the course of being served up in "Fraser's Magazine." Both are furiously anti-Catholic,—the "Old Traveller," even more so, if possible, than the "Veteran" one. Both run quite counter to the ready-made cant of Guide-books, and Ciceroni; and both speak out their minds with a freedom that is absolutely startling. If the one execrates St. Peter's with an energy that leads us to suspect he is not quite so "Old" as he pretends, the other execrates Palladio hardly less vigorously.

As a slight specimen of the former, we quote his opinion of St. Peter's: "*As a kaleidoscope for children*, it is worth preserving; as a temple of God, it is a profanation, a mockery, an absurdity, and rebuke. It may fulfil the purposes of a superstition bent on imposition, and only to be maintained by fraud and deceit. It may dazzle the miserable slave crouching to its marble gods, and enforce a kind of veneration for the working of its priests; but as a specimen of art, and an emblem of mortal power, it presents the most lamentable failure in the history of mankind." This is pretty well; there are, however, two other touches which we cannot help quoting, and which we would recommend to the consideration of the "Dublin Review." "A few barrels of gunpowder, judiciously lighted under St. Peter's, would send to heaven all of the Pope that is likely ever to get there." And perhaps our readers will think so when informed that "the morals of the hierarchy may be best exemplified by simply stating, that his present *Holiness* finds, in the passable person of a barber's wife, a *chère amie* to console the dulness of celibacy"!!!—so much for Gregory XVI., the present successor of St. Peter, and Vicegerent of Christ.

That writer certainly does not mince the matter; neither does the "Veteran," except indeed it be by making mince-meat of some of those upon whom he pounces. And of this latter, the language is frequently *tranchant*; his irony keen, his satire bitter, though at times playful and humorous withal, with here and there some flashes of genuine wit. We have heard his work abused as grossly personal; and, indeed, he does make exceedingly free with a great many names, but then they are of such people alone as have courted notoriety, nor does he drag them before the public an inch further than they had previously thrust themselves, although in a somewhat different plight. Probably, therefore, those who are most angry, are irritated not at the injustice of what he says, but because it is so just that it comes doubly home to them and sticks by them.

However, our proem is growing rather too lengthy, at least for our columns; let us, therefore, set before our readers at once an extract from what he says of Palladio; and we select his remarks on the Villa Capra, near Vicenza, that being an edifice with which most of them must be familiar, if only from engravings.

"The celebrated Villa Capra, situated about a mile from Vicenza, and misnamed the Rotunda,—it having nothing of the rotund about it, except in the odd shaped dome rising from its centre,—enjoys a reputation for which it is difficult to account, otherwise than by attributing its continuance to that superstition and indolence on the part of criticism, which induce uninquiring acquiescence in opinions no one would now venture to bring forward for the first time. Of regularity there is no want, the four fronts being perfectly alike, except as to some slight details, and each having an advanced hexastyle Ionic portico, with a lofty flight of steps leading up to it; yet regularity here seems carried to excess, for not only does it occasion a rather monotonous repetition, where propriety would have admitted of some variation of design, but it occasions the house to look as if nearly all entrance, and, in fact, renders it much smaller as a residence than at first sight it promises. No space is left for rooms except at the angles, the internal plan being cut up by the four passages leading from the porticos to the central hall or *salone*. This last-mentioned, again, by no means answers to our English ideas of a saloon, since, instead of being the principal apartment, it is a mere vestibule, and one, moreover, that is necessarily a common thoroughfare; added to which, its space and loftiness causes the other rooms to appear small and insignificant; neither does it make that display of beauty which would reconcile us to so much of the internal space being thus applied; for with the exception of the doors, it is almost naked, unless we can fancy the ugly projecting balustrade, forming a gallery on the level of the upper floor, to be any decoration. This want of embellishment does not render itself particularly perceptible, thanks to the extreme scantiness of light admitted through the small lantern on the summit of the dome, which is no more than sufficient to give the place the air of a dismal cavern. For so much space being lost in detached passages, and for the mode in which the rooms are insulated, some allowance is, perhaps, to be made, tradition informing us that the house was originally a *picnic* residence built for four brothers, each of whom had his particular *sala* and adjoining ante-room, while the *salone* was in common for them all and their attendants: why they could not have made as good shift with a single portico as with a single vestibule it is difficult to conjecture. However, the architect does not seem to have put his ingenuity at all to the stretch, because, although he has been liberal enough to assign a separate portico to each of the four co-proprietors, every one of the porticos affords access to two distinct apartments, so that instead of having one exclusively to himself and his particular visitors, each may be said to have been the owner of only the halves of two separate porticos. This remark certainly partakes largely of trifling hypercriticism; yet, where so much stress is laid upon the ingenuity displayed by the architect, we are warranted in looking for some particular evidence of it; nor, in excuse for the absence of it, can it be urged that he has manifested any happiness of invention or novel effect.

"The exterior is not much more commendable for its design than the interior for its accommodation, for when a person is told that there are four porticos he has nearly all its merits and pretensions summed up in that piece of intelligence; and should he not care to have his imagination considerably chilled, he will do well to draw upon his own fancy, without examining or inquiring into particulars. It is true the porticos project considerably from the building, and so far contribute to variety, both of shadow and of outline; at the same time, owing to their ends being closed up, with the exception of an open arch, there is a heaviness of appearance in them, and much of the character of such a feature is lost. As to the order, it is merely by courtesy styled Ionic, it bearing just that kind of resemblance to what its name denotes it as to render us all the more sensible of its deformity; whereas, were it something altogether different, we could not compare it [judge of it] by such a standard. The resemblance it bears to the Grecian Ionic generally, or to any of its varieties, is precisely that which an emaciated, cadaverous body, bears to one full of vigour and health. The shafts of the columns are both lanky and gouty; and the capitals have a truly consumptive look, and are without volume, or flow in their volutes, which are indeed so truly insignificant, when compared with those of the Grecian Ionic, that they almost cease to be indicial features of the order. Now, although Roman architecture offers hardly a single tolerable example of that order, except it be in detached columns and capitals applied to other buildings, surely a man who possessed any genius or taste must have been sensible of the imperfection of his models, and ought to have detected in what they were deficient, and endeavoured to produce something better, which he might have done without having seen any of the Grecian prototypes of the deteriorated Ionic of Rome and Italy. Such new productions might have been more unlike the originals than even the spurious Roman specimens are, and yet far superior to the latter."

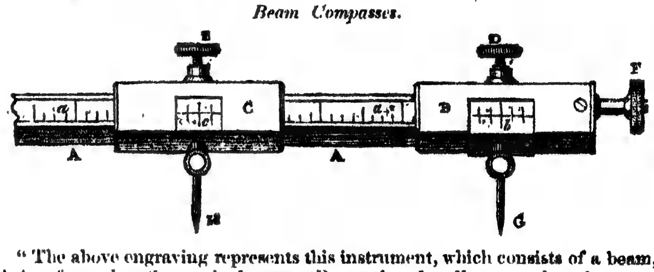
Herein we cordially agree with the writer, and consider it matter of regret that the *revivalists*, as they are termed, should almost at the very outset have imposed upon themselves and their followers such arbitrary and cramping rules as to columns and entablatures, which admit of equal, if not greater variety in their ornamental details than any other features, while they tolerated and even set the example of the utmost licentiousness, and of contrariety to classic feeling in almost every thing else. Notwithstanding the length of our extract, it does not contain the whole of the writer's remarks on that single edifice of Palladio's; hence it will be perceived that he is not one of those who give their opinion of a building in a brief sentence, or dispatch it with some epithet of unqualified admiration or reprehension. With equal minuteness does he discuss the merits of the *Teatro Olimpico*, which others have—it must be confessed rather childishly—extolled as a prodigy, both of conception and taste. "What," very reasonably asks our author, "can be more contrary to common sense than to dispose the seats in concentric curves, so that the greater part of the audience can see the performance only sideways, instead of placing them all in front, by making the rows of seats parallel to the stage?" He afterwards goes on to observe, that the stage or *scena*, and "the *practicable* alleys opening into it, are the most toyish, baby-house affair imaginable, and are so far from being calculated to enhance perspective illusion, as to be in utter contradiction to it," because "the actors must appear of the Brobdignagian size as they advance up those alleys. In fact, the centre one," he adds "becomes so narrow at its further extremity, that I question whether the starved apothecary in 'Romeo and Juliet' would not be fairly wedged in between the houses."

Among the other pieces of architectural criticism, that on Milan Cathedral is the longest, and comprises a very ingenious and plausible, if not entirely successful, defence of the intermixture of styles in the façade of that edifice. But for this we must refer our readers to the work itself, unless the specimens we have laid before them are so unsatisfactory, and the character we have given of it so unprepossessing, that they have no desire to become better acquainted with it. For our own part, we shall be most happy to meet with him again, and to listen to him whether discoursing on architecture, or exposing follies and knaveries, with more of piquancy and caustic pleasantry than of indulgent forbearance.

A Treatise on the Principal Mathematical Drawing Instruments employed by the Engineer, Architect, and Surveyor. By F. W. Simms, C. E. *With numerous wood-cuts.* London: John Weale, 1837.

This is a very useful little work for the pupil on entering the profession; it gives him an insight into the different instruments that are required in the office, and how they are to be applied. We make the following selection as an example of the work.

Beam Compasses.



"The above engraving represents this instrument, which consists of a beam, A A, of any length required, generally made of well-seasoned mahogany; upon its face is inlaid throughout its whole length a slip of holly or box-wood, *a a*, upon which are engraved the divisions or scale, either feet and decimals, or inches and decimals, or whatever particular scale may be required; those made for the use of the persons engaged on the Ordnance Survey of Ireland, were divided to a scale of chains, 80 of which being equal to six inches; which, therefore, represented one mile, that being the scale to which that important survey is being plotted. Two brass boxes, B and C, are adapted to the beam; the latter may be moved, by sliding, to any part of its length, and fixed in position by tightening the clamp-screw E. Connected with the brass boxes are the two points of the instrument, G and H, which may have any extent of opening by sliding the box C along the beam, the other box B being firmly fixed at one extremity. The object to be attained, in the use of this instrument, is the nice adjustment of the points G H to any definite distance apart; this is accomplished by two vernier or reading plates *b c*, each fixed at the side of an opening in the brass boxes to which they are attached, and afford the means of minutely subdividing the principal divisions *a a* on the beam, which appear through those openings. D is a clamp-screw for a similar purpose as the screw E, namely, to fix the box B, and prevent motion in the point it carries after adjustment to position. F is a slow motion screw, by which the point G may be moved any very minute quantity for perfecting the setting of the instrument, after it has been otherwise set as nearly as possible by the hand alone."

Railway Practice, with Plates. By S. E. Brees, C.E., &c. London: John Williams, 1837.

The value of such books as the one now before us cannot be too highly appreciated, particularly when they contain copies of the working drawings and specifications of Railways that are in progress, and being executed, under the directions of the most eminent engineers. The profession, and we may say also the public in general, cannot but admire the liberal feeling of those gentlemen who have so nobly lent their drawings for the purpose of publication; such a feeling we are sure will tend to raise their name, if possible, in the estimation of their professional brethren, and we trust that this degree of liberality will be supported by others with the same spirit, and not let it be said, as we have too often heard, and are sorry to say too true, that Englishmen are fond of letting foreigners have copies of their drawings which they refused to their own countrymen; but we do hope the bright example now before us will

reverse this order of things. We must here remark in good feeling, that the liberality of the contributors have not been met with the same degree of spirit by the publisher; we consider that more pains should have been taken, and the work better got up, and the plates engraved: no doubt we shall be answered that the work would not pay, and that the profession is not sufficiently numerous for an extensive sale, to repay the cost of such a publication; however, it is not our wish to depreciate the work, further than to say, that it cannot be considered as a work of art, but it must be strictly understood as a sound practical work, valuable not only to the student, but to every member of the profession. It is not now our intention to enter *seriatim* into a review of the several works contained in the book, but shall reserve our remarks to a future opportunity, when we shall enter into a minute review of the several designs; some of them we shall examine into critically, and state our opinion on the soundness of their construction, and the taste displayed;—we will for the present proceed to give a brief outline of the work, that the profession may be able to judge of its character and utility. It contains

40 plates and specifications of bridges, tunnels, turn-rails and retaining walls, on the London and Birmingham Railway; R. Stephenson, Esq., Engineer. The 14 first plates are details of the works on the extension line to Euston Square.

3 plates of bridges on the Great Western Railway; J. K. Brunel, Esq., Engineer.

3 plates of the skew bridge, over the Spa Road, on the Greenwich Railway; George Landman, Esq., Engineer.

2 plates and specifications of the viaduct over the valley of the Avon, and bridge over the River Trent, on the Midland Counties Railway; C. Vignoles, Esq., Engineer, and J. Woodhouse, Esq., Resident Engineer.

1 plate of the viaduct over the River Ribble, on the North Union Railway; C. Vignoles, Esq., Engineer.

7 plates of the sheds, turn-tables and cranes at the depôt on the Leeds and Selby Railway; J. Walker, Esq., Engineer, and George Smith, Esq., Resident Engineer.

5 plates of bridges on the Grand Junction Railway; Joseph Locke, Esq., Engineer.

2 plates and specifications of the cuttings and occupation bridge on the Slamannan Railway; John Macneil, Esq., Engineer.

2 plates of the aqueduct over the River Lune; Sir John Rennie, Engineer.

And 12 plates containing designs of viaducts, bridges, and tunnel fronts, by the Editor; all of which had better have been omitted, and the book confined entirely to works either executed or in progress.

We should advise that the plates be kept distinct from the letter-press, as, by folding and binding them in a Volume, they are not so convenient for reference.

The plates of a few copies of the work have been coloured, which better distinguishes the character of the construction.

A Practical Essay on the Construction and Management of Steam Engine Boilers, as now used in the Manufacturing Districts around Manchester No. 1. By R. Armstrong, C.E.

This work, professedly produced for the use of practical men, is written in a clear and intelligible style, which greatly enhances its value as a work of reference. Nothing very novel is elicited in the course of the first part of the second chapter, which has appeared; but the rules and data, based upon an extensive series of observations and experiments, are valuable, inasmuch as they are simple and of easy application, a recommendation of no mean value with the real mechanic, whose forte lies rather in mechanical combination, than in arithmetical analyses.

The mode by which the author conducted his preliminary experiments is well explained:—

"3. Amongst my earlier experiments, which were made on a smaller scale, was one with a common furnace, pot, or boiler, of cast iron, such as are usually set in kitchens; it was capable of holding eighteen to twenty gallons; the fire grate was six inches by eight, or one-third of a square foot in area, and the whole of the heating surface exposed was about three square feet. Into this boiler was measured two cubic feet of water, and after having caused it to boil, I then found, that by feeding the furnace with coal and the boiler with water, and at the same time managing the draught of the chimney so as to keep the water boiling nearly at a uniform rate, the consumption of good coal was at the rate of four and a half pounds per hour, and the quantity of water boiled away in that time was exactly two gallons, or very nearly one-third of a cubic foot.

"4. Now, as it is usual to reckon that the evaporation of one cubic foot of water per hour is sufficient to furnish steam for one horse power, we have only to multiply each of the foregoing results by three to obtain the following proportions:—

1 cubic foot of water evaporated per hour, requires
1 square yard, or 9 square feet, of heating surface,
1 square foot of fire-grate, and
[illegible] of good coal

We thus obtain what may be called a rough estimate of a boiler of one horse power, and with an expenditure of fuel approaching to the usual allowance of fourteen pounds of coal per horse per hour. This experiment, which was frequently repeated, was made with an open-topped boiler, which induced me to make several other experiments with a variety of small boilers, more nearly assimilated to the condition of an ordinary steam boiler attached to an engine at work; the results were, in all cases, whether under a pressure of four or five pounds per square inch, or open to the pressure of the atmosphere alone, so nearly agreeing with the above, that excepting increasing the quantity of water in the boiler, which seemed to increase the quantity of fuel used in getting up the steam, but at the same time lessened the other portion of the general consumption, by lessening the difficulty of regulating the fire, there was no other alteration that materially affected the results as given above."

The observations on the subject of burning smoke deserves attention.

"37. However, in the course of those experiments we always found that nothing tended so much to the accomplishment of both these objects as enlarging the furnace and flame bed, and where the draught of the chimney was good, also enlarging the fire grate. In adopting this last alteration, it was always found, that the maximum effect was produced when the area of the fire-grate was increased in a somewhat greater ratio than the effective heating surface was diminished;—that is, when a certain effect is to be produced, say for example, an evaporating power equal to the supply of a twenty-horse engine, which we have seen requires twenty square yards of effective heating surface, but from malconstruction of the boiler or other circumstances we have only eighteen yards, then the furnace will require to have a fire grate of *little more* than twenty-two square feet in area; or, if the heating surface be only sixteen yards, then the fire-grate will be required to be *more than twenty-four*, in fact about 25 square feet."

The formulæ and rules for finding the horse power, area of the fire-grates, and area of effective heating surface, will be found useful; but for information on this point, we refer the reader to the work itself, as the rules, with the examples, are too voluminous for extract into our pages.

We think the author has overlooked one of the greatest causes of priming, particularly in locomotives, viz., the foulness of the boiler; it is a fact well-known to all persons conversant with locomotives, that the engine primes in proportion as the water is dirty, and the remedy is to empty the boiler and clean it out, and when clean, the same boiler, under the same conditions of the valves, &c., will not prime at all; thus, it occurs to us, that the explanations given in the work are not satisfactory.

We recommend this work, notwithstanding, to every man connected with steam, whether he be a maker of boilers, or user of them.

The Churches of London. By George Goodwin, Jun., Architect, Associate of the Institute of British Architects; assisted by John Britton, Esq., F.S.A. London: C. Tilt, 1837.

This very useful and justly popular work has arrived at its eleventh number: each number contains two engravings of an interior and exterior view of one of our Metropolitan Churches, with critical notices, interspersed with well-executed wood engravings. The object of the author is to render typographical matter, by the aid of criticism, occasional reflections, disputations, and otherwise, interesting to the general reader, and which will ultimately draw his attention to the study of Church architecture. The author is entitled to the warmest encomium of the profession for his efforts in the endeavour to inculcate into the minds of the public a taste for this important branch of architecture. The work is intended to give accounts and illustrations of all the churches that are strictly within the limits of the city of London, and it is calculated not to exceed, when completed, 36 numbers which, when bound up in a volume, will not cost more than 2*l*. We shall notice the future numbers as they are published.

A Popular Treatise on the Warming and Ventilation of Buildings. By Charles John Richardson, Architect. *Illustrated with 18 Zinc Plates.* London: John Weale, 1837.

The system of warming buildings has often been written on by various authors, each advocating their own peculiar hobbies, and depreciating those systems which do not exactly suit their fancies, without attempting to enter into the subject philosophically or experimentally, but confine themselves to mere assertions. The work before us, we anticipated, was somewhat of a different cast; but we must say, that on perusing it we were much disappointed, and instead of it being a treatise on the warming of buildings generally, it is a treatise on warming buildings on Mr. Perkins' principle, so far as describing Mr. Perkins' apparatus; and showing how it may be applied to buildings of various descriptions, the author has done full justice to the inventor, not only in detailing the system, but also in his illustrations, which are particularly good. The work contains several plans and sections of public buildings, as the British Museum, Atlas Insurance Office, Strathfieldsaye House, Soane Museum, House of Commons, Registry Office, and New Justiciary Courts at Edinburgh, and several other buildings; showing how conveniently Mr. Perkins' system has been applied in

warming all these buildings by the circulation of warm water at high pressures through pipes of small dimensions (one inch tubes). The author thus describes the apparatus :

"The superiority of Mr. Perkins's apparatus, consists in his having availed himself to the utmost of the great advantages presented by water as a circulating medium for transmitting heat, and which, until his system appeared, had only been, as before seen, very insufficiently and imperfectly applied.

"The quantity of water necessary is reduced to a mere fractional part only of what has been before used. The apparatus is rendered smaller, the diameter of the tube is reduced from four inches to one inch only; and this is done with a proportionate degree of effect. The small quantity of water in immediate contact with the fire, receives the heat more rapidly; hence, a free and rapid circulation is caused.

"In its simplest form, the apparatus consists of a continuous or endless tube, closed in all parts and filled with water; about *one-sixth part* of which tube being coiled in any suitable form, is placed in the furnace, and the other five-sixths are heated by the circulation of the hot water which flows from the top of this coil, and cooling in its progress through the building, returns into the bottom of the coil to be re-heated.

"The procuring a circulation of water through such small tubes, is obtained by the extreme expansibility of water, which is much greater than any other fluid. We have only to consider the relative specific gravities which two columns of water must bear to each other, one column having been rendered lighter by the application of heat, which expands it, and fills it with minute bubbles of steam which rise rapidly to the upper part of the tube, and becoming there condensed into water again, and then forming another column of water, which, from having no bubbles of steam in it, must necessarily descend in proportion to the expansion of water in the ascending column. Knowing steam to be 1800 times lighter than water, it may easily be conceived how readily a small stream of water may be kept in constant circulating motion; and, when combined with its power of absorbing heat, it is not surprising that it should extend through a considerable length of pipe before it cools so as to be inefficient.

"A tube, called an expansion-tube, is placed above the highest level of the small tubes led through the various apartments of the building. The filling-tube of the apparatus is placed on a level with the bottom of this tube, so as to perfectly fill all the small tubes, and yet prevent the possibility of filling the expansion tube itself. This tube is generally of larger diameter than those which are used as heating surfaces, and its length is proportioned to the quantity of tube to which it is attached, and being thus left empty, allows the water, as it becomes heated, to expand without endangering the bursting of the smaller tubes.

"Water, when heated from forty degrees to two hundred and twelve degrees, expands about five per cent., and Mr. Perkins, senior, has proved, by means of his powerful compressing machine, that it requires 28,000lbs. to the square inch to compress water five per cent.; hence the necessity of allowing sufficient expansion for the water.

"Practice has proved, that fifteen to twenty per cent. of expansion space is ample for the greatest heat which can be attained by hot water.

"The natural tendency to ascend of the column of heated water, is aided as much as possible by so placing the furnace in the building, that the tube proceeding from the top of the coil can be carried straight up at once to the highest level where the water has to circulate, and where the expansion-tube is placed; from this point two or more descending columns can be formed, it being only necessary to connect them in one tube before entering the furnace.

"The heat is communicated to the atmosphere of the building from the external surface of the tubes, which are either coiled up and placed in pedestals, ranged round the room behind skirting boards, with open trellis work in front,—sunk in stone floors, or placed in any manner most convenient. * *

"The temperature of Mr. Perkins's tubes can be made to vary from 150 degrees to 300 degrees, in rooms where great heat is desired, such as drying-houses, &c., a temperature from 300 degrees to 400 degrees can easily be obtained."

Mr. Richardson has omitted to show the quantity of fuel consumed for heating a given length of pipe, or space of building, so very important to support the system he advocates. Throughout the work there is only one passage that in any way alludes to it: after giving a description of the plan adopted for warming Mr. Cadell's establishment at Edinburgh, which is done by a circulation of hot water through about 1000 feet of tubing, the author states, that

"The whole daily consumption of fuel in Mr. Cadell's establishment is three quarters of a cwt., of which one-third is coal and two-thirds coke, from the gas-works; this quantity lasts till night."

In the second part of the work, which treats on ventilation, the author has given several useful hints, and shows how easily a good system of ventilation might be obtained.

"In the ventilation and warming of a private dwelling, I would begin first with the staircase. This we ought to consider the principal artery of the house; and if this was well warmed by a current of warm fresh air flowing into it, and a constant change effected by a ventilating outlet warmed so as to ensure its effective operation, great part of the business would be effected, as the staircase would supply all rooms not in use with warm air in a sufficient degree, and would gradually ventilate the whole building, rendering it unnecessary to have further ventilation, except in the principal living and sleeping rooms of the family.

"Where the latter was desired, by placing two or more spare columns of tubing in flues concealed within the thickness of the wall, two flues, or even one flue, properly constructed for the purpose, might be made to ventilate every room of a London house."

In an Appendix to the work a brief description is given of warming and ventilating by gas, Mr. F. A. Beinhardt's system by heated air, Dr. Arnot's air stove, and the various plans that have been introduced at different times for warming and ventilating the Houses of Parliament.

A Practical Treatise on Warming Buildings by Hot Water. By Charles Hood, F.R.A.S. *Illustrated by numerous Wood-cuts.* London: Whittaker and Co., 1837.

We have not space or time to review this work minutely, and must defer our remarks for the next Number; we perceive that it fully confirms our prefatory remarks in the preceding review, what one author approves another condemns. In the work before us, the Author's remarks on Mr. Perkins's principle of Warming Buildings, or "the high pressure hot-water apparatus," are at variance with Mr. Richardson's description and notions.

A Treatise on the Strength of Timber, Cast Iron, Malleable Iron, and other Materials. By Peter Barlow, *F.R.S., &c.* London: John Weale.

[SECOND NOTICE.]

In our last Number we noticed this Book, and made several extracts, to show the value of the work;—and to render our extracts more complete, and to show that the author has considered the strength of Timber as applied in every variety of cases, and also to show the value of his rules, we give the following additional extracts *on the elasticity of Timber.*

"Problem IV.—*To determine the Dimensions of a Beam, capable of supporting a given Weight with a given degree of Deflection, when fixed at one end.*

"*Rule.*—Divide the weight in lbs. by the reduced tabular value of E,* multiplied by the breadth and deflection, both in inches; then the cube root of the quotient multiplied by the length in feet, will be the depth required in inches. †

"*Example* I.—A beam of Riga fir is intended to bear a load of 665 lbs. at its extremity, its length being 5 feet, its breadth 4 inches, and the deflection not to exceed $\frac{1}{4}$ of an inch.

"In this case the tabular value of E is 96; hence, $\frac{665}{96 \times 4 \times \frac{1}{4}} = 6{\cdot}88$; the cube root of which is 1·902; hence, $5 \times 1{\cdot}902 = 9{\cdot}51$ inches, the depth required.

"By reference to Example I. of Prob. II. it will be found, that a beam of 6 inches depth would be sufficient to bear the load; but when, from the nature of the construction, only a limited degree of flexure can be allowed, this mode of calculation becomes necessary.

"*Note* 1.—When the weight is uniformly distributed over the length of the beam, the deflection will be only $\frac{3}{8}$ths of the deflection from the same weight applied at the extremity, and in the rule consider the weight reduced in this proportion.

"*Note* 2.—If the beam be a cylinder, the deflection will be 1·7 times the deflection of a square beam, other circumstances being the same.

"*Note* 3.—In the above examples the reduction of results to the differences depending on the specific gravity is not shown, neither is it applicable in practice; but for theoretical comparison it is important, and may always be performed by stating, as the specific gravity of the tabular specimen is to the load supported in any example, so is the actual specific gravity of the specimen it would support under similar circumstances.

"Problem V.—*To find the Dimensions of a Beam, capable of sustaining a given Weight with a given degree of Deflection, when supported at both ends.*

"*Rule.*—Multiply the weight to be supported in lbs. by the cube of the length in feet. Divide this product by 32 times the reduced tabular value of E (see Note 1, Prob. IV.), multiplied into the given deflection in inches, and the quotient is the breadth multiplied by the cube of the depth in inches.

"*Note* 1.—If the beam be intended to be square, then the breadth is equal to the depth, and the fourth root of the quotient is the depth required.

"*Note* 2.—If the beam be a cylinder, multiply the quotient by 1·7, and then the fourth root will be the diameter of the cylinder.

"*Note* 3.—When the load producing the depression is greater than one-fourth of the greatest stress the beam would bear, it is too great to be trusted in construction; but in timber this limit is seldom exceeded on account of its flexibility.

* "The value of E in these rules is the tabular value divided by 1728, which renders it unnecessary to reduce the length in feet into inches.

For English Oak, E = 105
For Riga Fir, E = 96

† "This rule is applicable to the imperfect fixing which obtains in practice; but the more perfect the mode of fixing is, the nearer the deflection will be to half that determined by the rule, and ordinary cases will usually be a mean between these results."

"*Note* 4.—If the load be uniformly distributed over the length, the deflection will be $\frac{5}{8}$ths of the deflection from the same load collected in the middle. And in the rule, employ $\frac{5}{8}$ths of the weight of the load instead of the whole load.

"*Example* I.—The length of the fir shaft of a water-wheel being 20 feet, and the stress upon it 7 tons, it is required to determine its diameter so that its deflection may not exceed ·2 of an inch.

"The reduced tabular value of E=96, or more exactly 32 E = 3075, and 7 tons=15680 lbs.; hence (by the Rule and Note 2)

$\frac{1·7 \times 15680 \times 20^3}{3075 \times ·2} = 346730$ nearly. The fourth root of this sum is 24·3 inches, the diameter required.

"Shafts which are to be cut for inserting arms, &c., will require to be larger, in a degree equivalent to the quantity destroyed by cutting.

"The flexure of shafts ought not to exceed $\frac{1}{100}$ of an inch for each foot in length, this being considered the limit; and it will be always desirable to make shafts as short as possible, to avoid bending.

"*Example* II.—The greatest variable load on a floor being 120 lbs. per superficial foot, it is required to determine the depth of a square girder to support it, the area of the floor sustained by the girder being 160 feet, the length of the girder 20 feet, and the deflection not to exceed half an inch.

"The reduced value of E for Riga fir is 96 or 32 E = 3075, and the weight is 120 × 160 = 19200 lbs. uniformly distributed; hence (by Note 4) we have $\frac{\frac{5}{8} \times 19200 \times 20^3}{3075 \times \frac{1}{2}} = 62440$. The fourth root of this number is 15·8 inches, the depth required.

"The deflection of $\frac{1}{40}$th of an inch for each foot in length is not injurious to ceilings; indeed, the usual allowance for settlement is about twice that quantity. Ceilings have been found to settle about four times as much without causing cracks, and have been raised back again without injury.

"The variable load on a floor seldom can exceed half the quantity of 120 lbs. on a superficial foot, unless it be in public rooms; hence, the number may be taken from 60 to 120, according to circumstances.

"The same rule applies to joists of different kinds for floors; the area of the floor supported by the joists being multiplied by from 60 to 120 lbs. per superficial foot, according to the use the room is designed for.

"*Example* III.—To determine the size of a rafter for a roof to support the covering of slate, the distance between the supports being 6 feet, and the weight of a superficial foot, including the stress of the wind, being 56 lbs., and the deflection not to exceed $\frac{1}{40}$th of an inch for each foot in length.

"The tabular value gives

32 E = 3075, the weight = 56 × 6 = 336 lbs.; hence (by Note 4)

$$\frac{5 \times 336 \times 40 \times 6^3}{8 \times 3075 \times 6} = 98·34.$$

"If the breadth be made 2½ inches, then

$$\frac{98·34}{2·5} = 39·3;$$

and the cube root of 39·3 is 3·4 inches, the depth required.

"*Minutes of Proceedings of the Institution of Civil Engineers, containing Abstracts of Papers, and of Conversation for the Sessions of* 1837."

(Continued from Page 26.)

"February 14, 1837.—The President in the Chair.

"'*Description of Mr. Henry Guy's method of giving a true spherical figure to balls of Metal, Glass, Agate, or other hard substances.' Communicated by Bryan Donkin, Esq., V.P. Inst. C.E.*

"The method adopted by Mr. Guy consists simply in applying to practice the principle, that if a ball can be made to revolve rapidly in every possible direction, or, in other words, if during such revolution its axis of rotation be constantly changing its angular position within the ball itself, whilst a grinding tool is applied to the surface of the ball, the most prominent parts of that surface will be first acted on by the grinder, and by continuing the operation the whole of the higher parts of the surface will be progressively ground off, and the ball will ultimately be left of a perfect spherical shape. Mr. Guy effects this, by placing the ball betwixt the faces of two wooden chucks fixed to two lathe mandrils, such as are used in common turning lathes, with their axes exactly in a line with each other. A quick motion is given to the mandrils in the usual way by two bands, so applied that the mandrils are placed in opposite directions; the ball being compressed betwixt the chucks turns, notwithstanding the friction of the tool. The tool is a bar of brass or iron, with a conical hole near one end, the larger diameter of which is made a little larger than the diameter of the ball.

"'*On the Construction of Railways of continuous Bearing; by John Reynolds, A. Inst. C.E.'*

"The author states the conditions essential for a good railway to be as follows. 1. That it should be the closest practical approximation to a perfect plane of perfect stability. 2. That it should be adapted to prevent or to neutralize the vibrations from the impact of imperfect cylinders rolling on imperfect planes. 3. That it should possess the greatest durability and the greatest facility of being repaired, which are compatible with the above conditions. Mr. Reynolds proposes trough-shaped cast-iron bearers having rectangular bearing surfaces, the angular point being downwards. Thus a section of the bearing part of the rail across its length is a right angle, with its vertex downwards. By this peculiar shape the sustaining area is increased, a greater resistance to vertical pressure is consequently obtained, and the lateral stability of the rail is secured. The rails are to be laid in earth, ashes, or broken stone and gravel, and the sustaining surface of the earth may have any requisite density communicated to it by rolling or beating the earth at the sides, so as to give it sufficient density to resist the pressure to which the rail is to be subjected. The mass being composed of materials which will not readily yield or slip away, will be capable of farther condensation by any subsequent pressure not exceeding that to which it had been originally subjected by the beaters or rollers acting at the sides.

"The rails which Mr. Reynolds uses are of two kinds; rails wholly of cast-iron, cast in one piece, and rails either of wrought or cast-iron laid on a sill of wood, the wood being placed in a cast-iron bearer of the shape already described. The rails, sills, and bearers in this latter construction, break joint with each other, and are held together by bolts passing through all three. Thus one continuous structure is formed throughout the whole line, and the fracture of the three parts in the same place is highly improbable. The vibrations will be neutralized by the sill of wood acting as a partially elastic cushion in receiving the concussion to which the rails are subjected; and this latter mode of construction is considered preferable, as admitting of the use of either cast or wrought-iron rails."

"February 21, 1837.—Bryan Donkin, Esq., V.P., in the Chair.

"The construction of railways on the principle of continuous bearing, as adopted by Mr. Reynolds, and described in his paper, read at the last meeting, was discussed. Some of the rails and bearers cast in a single piece having been laid on Chatmoss, inquiries were made as to how they had answered. It was stated, that they were kept in order at less trouble than the others, and that they showed no tendency to sink. It was intended to use the commonest timber for the sills; the wood having been boiled in tar, and allowed to cool in the tar, becomes so saturated with tar that it will not imbibe moisture.

"'*A Steam Expansion Table; by George Edwards, M.Inst. C.E.'*

"In the paper explanatory of this table the author remarks, that it has become a matter of interesting inquiry, why the expansive property of steam is as yet so little used, when attention has been directed so much to the economizing fuel by improved boilers, and other similar means; and the more so as patents were taken out by Hornblower in 1781, by Watt in 1782, and by Woolf in 1804, for working steam expansively. The objections to the use of high pressure steam may perhaps be an obstacle, but there are many cases, as in the engines of tug-boats, to which these objections cannot apply.

"Very incorrect notions having existed of the expansive properties of steam, the author has, according to the admitted law, 'that (the temperature being constant) the bulk is inversely as the pressure,' constructed a table, showing at one view the resulting pressure on the expansion of a given volume of steam of given density, and *vice versa*.

"Mr. Edwards then describes the construction and method of using the table, so as to answer at once questions similar to the following: 'Required, the pressure of 60 lb. steam when expanded three times its volume.' 'In a high-pressure engine, working expansively, required the length of the stroke at which to cut off the steam, that the pressure may be 14 lbs. at the end of the stroke.' In a Woolf's engine, working 54 lb. steam, required the capacity of the larger cylinder, the smaller being unity, so that the pressure of the steam shall be 4 lbs. on the completion of the stroke of the large piston,' &c. &c.

"With respect to the principle on which this table is calculated, it was stated that the temperature does not remain constant, and that the pressure falls off most rapidly on the steam being cut off, and reference was made to some experiments made by Mr. John Taylor on this subject."*

"February 28, 1837.—The President in the Chair.

"'*On a peculiar form of Rail, and the Construction of Railways in America and Germany; by Herman Koehler, of Leipzig, M.Inst. C.E.'*

"The pattern, which the author describes, is by American engineers called the inverted T rail (⊥), and was introduced in order to avoid trouble and expense, which railways are liable to where the rails are placed in chairs and fastened with keys. The material used for this need not be of first quality, but in cases where it is expedient to support a general confidence in the quality of the iron, good and sound rails can be made of two-fifths of No. 2, Welsh iron, and three-fifths of No. 3, employing the better quality for the head and bottom, and No. 2 for the stem of the rail, rolled in such manner that the lamina of the iron lie horizontally throughout.

"The experience of all railways seems to confirm the opinion that chairs and keys to keep the rails firm to their places are a great and expensive inconvenience, and a dangerous construction, whether wood or iron be the material of the keys. The author then details the advantages of the rail, especially if laid on a continuous line of stone or wooden sleepers at a small distance apart.

"Wooden railways are at this time used in Germany, and the author has laid nine miles between Leipzig and Dresden. Wooden sleepers, 8 inches square, are placed upon trenches cut across the embankment at every yard, and filled up with a bed of broken stones, one foot deep. Notches 3½ inches deep are cut into these cross-ties to receive the wooden rails of 6 by 9 inches, which are shod with iron plates of one inch thickness and 2½ inches width. At their joints they put together, on iron plates one-eighth of an inch thick, to prevent their being pressed into the wood. The rails are wedged firmly to the sleepers by wooden wedges. The head of the spikes with which the iron rails are fastened to the wood are of a conical form, and fit into corresponding holes, these having an elliptical form to prevent the spike from being drawn or bent on the contraction and expansion of the iron rail. The ends of every iron plate rail are fastened with screw-bolts, passing through the whole height of the wooden rails, firmly to their places, which is a very important precaution, as the engines are apt to catch the points of the plate rails with their wheel flanches and to run off.

"'*A Drawing and Description of a new Lewis, by Henry Robertson, Glasgow.' Communicated by the Author.*

"The proposed Lewis consists of two pieces of iron, whereof each is a bent lever, connected at a joint by a strong bolt. When the upper or longer arms are drawn together by the power, the under or shorter arms inserted into the hole are forced against the sides, and, by properly increasing the proportion of the upper to the under arm, any necessary power may be given to the instrument.

"The advantages of this Lewis, as compared with the one of three pieces in general use are, that it can be inserted into and removed from the hole in far less time; it adapts itself to the form of the hole, all fitting and plugging with slips of iron being unnecessary, and exerting its pressure directly against the sides of the hole, is less apt to chip off the edges and endanger the falling of the stone.

"'*Experiments on the Strength of various kinds of American Woods exposed to a Transverse Strain; by Lieutenant Denison, of the Royal Engineers, A. Inst. C.E.'*

"These experiments were undertaken with the view of establishing, first, some common standard of comparison between the woods in general use in that country

---

* "See *Minutes of Conversation*, March 1, and 8, 1836."

and in our own; and secondly, to ascertain the change in strength caused by seasoning. The latter series of experiments, unfortunately, was not made."

"March 7, 1837.—The President in the Chair.

"'*On Experiments on the Strength of Materials. By Thomas Webster, M.A., Sec. Inst. C.E.*'

"The object of this paper was to point out the importance, in making experiments on the strength of materials, of beginning with weights sufficiently small. In the series of experiments on the strength of various timbers by Lieutenant Denison, laid before the last meeting of the Institution, the first weights are in some cases too large, for from the commencement the deflection increases more rapidly that the imposed weight.

"The points to be ascertained in all experiments of this kind are, first, the weight which a beam can bear, the elasticity being unimpaired, or the Elastic Weight; and, secondly, the Breaking Weight. So long as the deflection increases in exact proportion with the increase of the weight, we may consider that the elasticity is unimpaired; but if the deflection increases in a higher ratio, that is, if the deflection for one cwt. be *one* inch, and for two cwt. more than *two* inches, we may suspect that some violence is done to the elastic force of the material. Thus a guide is furnished us in our observations; the weight before which this ratio is observed to change must be considered as the Elastic Weight. When a beam is to be broken, the effect of time should be noticed, and the increased deflection after a given number of seconds recorded.

"The experiments of Lieutenant Denison bear out these remarks; for it will be seen, that the point at which he has noted the first permanent set is, in very many cases, immediately after the change which is here laid down as the condition for determining the elastic weight.

"With respect to the strength of materials, Mr. Cottam stated that it had often occurred to him, whether, if a beam be loaded by ever so small a quantity beyond the Elastic Weight, this beam would not in time be broken. This consideration might, he thought, explain some apparent difficulties, as when a beam breaks suddenly without any increase in the weight, but having been loaded to the same amount for many years.

"Mr. Hawkins mentioned a case, in which a beam that deflected too much had been sawn down its middle and bolted up, so that its depth was increased in the centre from 10 to 11 inches. The effect of this was, that the deflection, instead of being about 1¼ inch, was only one-eighth of an inch. Was this great increase of strength to be attributed to the increase of depth simply, or to the lower half having become a truss and the upper a strut?"

"March 14, 1837.—The President in the Chair.

"The decay of timber in contact with stone was discussed, and several instances were mentioned in which the only decayed part of timber was that in contact with stone. This decay is entirely obviated by inserting the wood in an iron shoe, or by placing a thin piece of iron betwixt the wood and the stone. Several cases were mentioned in which the iron shoe had been found a complete protection against dry rot and decay; a hard crust is formed on the timber in contact with the iron, which seems effectually to preserve it. It was suggested that the system of grouting must contribute to the early decay of timber; bond timber had consequently been replaced by bond iron. Bond timber is used very generally at Manchester, and answers exceedingly well, but the high temperature of the buildings may be a preventive against the decay of the timber, as the walls are very soon dried.

"The subject of the strength of materials was resumed from the last meeting, and especial reference was made to the experiments by Mr. Hodgkinson on the strength of iron girders, published in the Transactions of the Manchester Society. In this paper Mr. Hodgkinson supposes the forces of extension and compression to have a ratio ꞉ : u; and not that, within the elastic limit at least, this ratio is a ratio of equality.

"Also, these experiments are directed especially to determining the form of beam which will be strongest up to the instant of fracture; or, in other words, the beam which will have the greatest breaking weight without any reference to the elastic weight.

"These principles are contrary to those laid down by Tredgold, and to the opinions of many persons of great experience. Mr. Donkin and Mr. Francis Bramah maintained that within the elastic limit the forces of extension and compression are equal; that consequently within this limit the deflection will be the same, whether the beam is laid with a particular edge highest or lowest; that a beam, for instance, whose section is a triangle, will exhibit the same deflection within the elastic limit, whether the vertex or base of the triangle be laid uppermost; beyond this limit, however, the case is different.

"The strength of a beam, according to Mr. Hodgkinson's experiments, depends on the bottom flanche; by increasing this he had made beams for which the breaking weights were 4000 the square inch of surface of section, whereas Tredgold's strongest forms were about 2500 the square inch."

EXTRACTS FROM PAPERS READ BEFORE THE ROYAL SOCIETY, 1836.

"*On certain Parts of the Theory of Railways. By the Rev.* DIONYSIUS LARDNER, *LL.D., F.R.S.*

"THE author observes, in his prefatory remarks, that an extensive and interesting field of mathematical investigation has been recently opened in the mechanical circumstances relative to the motion of heavy bodies on railways; and having collected a body of experiments and observations sufficient to form the basis of a theory, he purposes, in the present paper, to lay before the Society a series of mathematical formulæ, embodying the most general expressions for the phenomena of the motion of carriages on these roads.

"The author begins by investigating the analytical formulæ for the traction of trains over a level line which is perfectly straight, and finds, first, the distance and time within which, with a given amount of tractive power, the requisite speed may be obtained at starting; and also the point where the tractive power must be suspended, previous to coming to rest. The excess of tractive power necessary to get up the requisite speed is shown to be equal to the saving of tractive power previous to a stoppage; and formulæ are given for the determination of the time lost under any given conditions at each stop.

"The motion of trains in ascending inclined planes which are straight, is next considered; and formulæ are given combining the effects of friction and gravity, in opposition to the tractive force. The circumstances which affect every change of speed, and the excess of tractive force necessary, in such cases, to maintain the requisite speed, are determined; as well as the other circumstances already stated with respect to level planes.

"The friction of trains upon descending planes is next investigated, and an important distinction is shown to exist between two classes of planes; viz., those whose acclivities are inferior to the angle of repose, and those of more steep acclivities. A remarkable relation is shown to exist between the tractive forces in ascending and descending the first class of planes. For descending planes of greater acclivity than the angle of repose, the use of breaks becomes essentially requisite. The effect of these contrivances is investigated, as well as the motion of trains on the accidental failure of breaks.

"In any attempts which have been hitherto made to obtain the actual velocities acquired by trains of carriages or waggons under these circumstances, an error has been committed which invalidates the precision of the results, the carriages having been treated as sledges moving down an inclined plane. The author has here given the analytical formulæ by which the effect of the rotatory motion of the wheels may be brought into computation; this effect, depending obviously on the amount of inertia of the wheels, and on the proportion which their weight bears to the weight of the waggon.

"The properties investigated in this first division of the paper, are strictly those which depend on the longitudinal section of the line, presumed to be straight in every part of its direction. There is, however, another class of important resistances which depend on the ground-plan of the road, and these the author next proceeds to determine.

"The author then gives the analytical formulæ which express the resistance arising,—*first*, from the inequality of the spaces over which the wheels, fixed on the same axle, simultaneously move; *secondly*, from the effort of the flanges of the wheels to change the direction of the train; and *thirdly*, from the centrifugal force pressing the flange against the side of the rail. He also gives the formulæ necessary to determine, in each case, the actual amount of pressure produced by a given velocity and a given load, and investigates the extent to which these resistances may be modified by laying the outer rail of the curve higher than the inner. He assigns a formula for the determination of the height which must be given to the outer rail, in order to remove as far as possible all retardation from these causes; which formula is a function of the speed of the train, the radius of the curve, and the distance between the rails.

"In the latter part of the paper, the author investigates the method of estimating the actual amount of mechanical power necessary to work a railway, the longitudinal section and ground-plan of which are given. In the course of this investigation he arrives at several conclusions, which, though unexpected, are such as necessarily arise out of the mechanical conditions of the inquiry. The first of these is, that all straight inclined planes of a less acclivity than the angle of repose, may be mechanically considered equivalent to a level, provided the tractive power is one which is capable of increasing and diminishing its energy, within given limits, without loss of effect. It appears, however, that this condition does not extend to planes of greater acclivities than the angle of repose; because the excess of power required in their ascent is greater than all the power that could be saved in their descent; unless the effect of accelerated motion in giving momentum to the train could properly be taken into account. In practice, however, this acceleration cannot be permitted; and the uniformity of the motion of the trains in descending such acclivities must be preserved by the operation of the break. Such planes are therefore, in practice, always attended with a direct loss of power.

"In the investigation of the formulæ expressive of the actual amount of mechanical power absorbed in passing round a curve, it is found that this amount of power is altogether independent of the radius of the curve, and depends only on the value of the angle by which the direction of the line on the ground-plan is changed. This result, which was likewise unexpected, is nevertheless a sufficiently obvious consequence of the mechanical conditions of the question. If a given change of direction in the road be made by a curve of large radius, the length of the curve will be proportionably great; and although the intensity of the resistance to the tractive power, at any point of the curve, will be small in the same proportion as the radius is great, yet the space through which that resistance acts will be great in proportion to the radius: these two effects counteract each other; and the result is, that the total absorption of power is the same. On the other hand, if the turn be made by a curve of short radius, the curve itself will be proportionately short; but the intensity of the resistance will be proportionately great. In this case, a great resistance acts through a short space, and produces an absorption of power to the same extent as before.

"In conclusion, the author arrives at one general and comprehensive formula for the actual amount of mechanical power necessary to work the line in both directions; involving terms expressive, *first*, of the ordinary friction of the road; *secondly*, of the effect of inclined planes, or *gradients* as they have been latterly called; and, *thirdly*, of the effect of curves involving changes of direction of the road, the velocity of the transit, and the distance between the rails; but, for the reason already stated, not comprising the radii of the curves.

"Although the radii of the curves do not form a constant element of the estimate of the mechanical power necessary to work the road, nevertheless they are of material consequence, as far as regards the safety of the transit. Although a short curve with a great resistance may be moved over with the same expenditure of mechanical power as a long curve with a long radius,

yet, owing to the intensity of the pressure of the flange against the rail, the danger of the trains running off the road is increased: hence, although sharp curves cannot be objected to on the score of loss of power, they are yet highly objectionable on the score of danger.

"In the present paper, the author has confined himself to the analytical formulæ, expressing various mechanical effects of the most general kind, the coefficients and constants being expressed merely by algebraical symbols: but he states that he has made an extensive series of experiments within the last few years, and has also procured the results of experiments made by others, with a view to determine the mean values of the various constants in the formulæ investigated in this paper. He has also, with the same view, made numerous observations in the ordinary course of transit on railways; and he announces his intention of soon laying before the Society, in another paper, the details of these experiments, and the determination of the mean values of these various constants, without which the present investigation would be attended with little practical knowledge.

"*On the Valuation of the mechanical effect of Gradients on a line of Railroad.*" *By* PETER BARLOW, *Esq., F.R.S.*

"The exact amount of the influence of ascents and descents occurring in the line of a railway on the motion of a load drawn by a locomotive engine having been differently estimated by different persons, the author was induced to investigate the subject. A few observations are premised on the erroneous assumptions which, he conceives, have in general vitiated the results hitherto deduced. The first of these is, that the expenditure of power requisite for motion is equal to the resistance to traction, whereas it must always greatly exceed it. No account, he remarks, has been taken of the *pressure* of the atmosphere on the piston, which the force of the steam has to overcome before it can be available as a moving power. Another source of error has been, that the statical and dynamical effects of friction have been confounded together; whereas they are the same in amount only when the body is put in motion by gravity, but not when it is urged down an inclined plane by an extraneous force. In the latter case these effects are no longer comparable, friction being a force which, in an infinitely small time, is proportional to the velocity, while that of gravity is constant at all velocities; or, in other words, the retardation from friction is proportional to the space described, while that from gravity has reference only to the time of acting, whatever space the body may pass over in that time. It is an error to assume, that the mechanical power of the plane is equivalent to a reduction of so much friction; for the friction down the inclined plane is the same as on a horizontal plane of the same length, rejecting the trifling difference of pressure; and the whole retardation in passing over the plane, or the whole force required to overcome it, is the same at all velocities, and by whatever force the motion is produced; but the assisting force from gravity is quite independent of the space or of the velocity.

In the investigations which the author has prosecuted in this paper, he assumes that equal quantities of steam are produced in the same time at all velocities; and he adopts for his other data, those given by Mr. Pambour in his Treatise of Locomotive Engines. He deduces a formula from which, the speed on a level being given, we may compute the relative and absolute times of a train ascending a plane, and consequently also the ratio of the forces expended in the two cases, or the length of an equivalent horizontal plane; that is, of one which will require the same time and power to be passed over by the locomotive engine as the ascending plane.

"The next objects of inquiry relate to the descent of trains on an inclined plane, and comprise two cases: the first, that when the power of the engine is continued without abatement; and the second, that when the steam is wholly excluded, and the train is urged in its descent by gravity alone. The author arrives at the conclusions, that in the first of these cases, when the declivity is one in 139, the velocity on becoming uniform will be double that in a horizontal plane; and that for a declivity of one in 695, the uniform velocity of descent will be one-fifth greater than on the horizontal plane; and this, he observes, is perhaps the greatest additional velocity which it would be prudent to admit. A plane of one in 695 is therefore the steepest declivity that ought to be descended with the steam-valve fully open; all planes with a declivity between this and that of one in 139 require to have the admission of steam regulated so as to modify the speed, and adjust it to considerations of safety; and lastly, all planes of a greater slope than this last require, in descending them, the application of the brake."

ORIGINAL PAPERS AND COMMUNICATIONS.

ON THE STANDING ORDERS, PRACTICE, AND FEES OF THE HOUSE OF COMMONS.

WE are happy to find that the Standing Orders of the House of Commons are yet under consideration, and that the Speaker is pledged to re-open the subject. No doubt, there is much to do, and with equal certainty we may add, there is much to *undo*. Last session the House, in trying to remedy one evil, created another and a greater. During the mania of speculation, it is certain that there were dishonest schemes as well as honest schemes, foolish ones, as well as wise ones impracticable as well as practical and useful. This evil no one affects to doubt; yet taking it to be the extent of accusation (which was immeasurably beyond the extent of proof), still we think it would not augur "absolute wisdom" to say there shall be *no schemes of public improvement at all.* It is like cutting off the head of a patient to cure a pimple on his nose, or a wart on his thumb; yet, to this extent the House of Commons has gone, by its Standing Orders of last session, as to Railways. We believe, there is not a solitary new railway projected, or rather propounded to Parliament this session. We have heard it argued, and that too successfully, in the very same House that has thus arrested the making of those internal communications which vastly augment the capabilities and wealth of the country—we have heard it argued in that same House, that it was good for the country to employ its capital and its people, by digging holes one day and then filling them up the next; but very, very different is the doctrine now held. The "surplus population" are not to be employed in even useful labour—the sacred right of private property is to be invaded, and men are not to be allowed to expend their capital as they please, because, forsooth, some projectors have been too sanguine, and some speculators too silly—men's money is to be kept in their pockets by Act of Parliament! You may throw away thousands on the bonds of other countries, if you please—you may gamble as much as you like in your own—you may visit aristocratic or democratic "hells," to your heart's content;—nay, you may meet with "grave and *legislative* seigniors—your much approved and very honoured masters," who, thus restraining you from ruining yourself in your own way, ruin you in theirs;—but your public ways you must not amend, railroads you must not make, branches, necessary and calculated upon to join the great trunks, must be suddenly and forcibly arrested, rendering these very trunks unprofitable, unpopular, and consequently unsuccessful, and all this must be done to punish the country for having acted upon the opinion which the Right Honourable Sir Robert Peel, amid the cheers of that very House, expressed in favour of the making and maintaining of railways throughout the country!

It really is at once lamentable and laughable to observe the glaring inconsistencies of the House of Commons. This year, railroads are all the rage, and the people are cheered on to their support—the next, they are worthless and senseless speculations, and the people must be debarred from engaging in them. *Now* we have honourable Members acting as Directors, or perhaps more often as shareholders, by wholesale, and *now* we see exactly the same men, after having sold out, the foremost to denounce the very system of which they had previously been the patrons! Nevertheless it must be confessed they were evils, and these evils required correction; but let us see what those evils were.

Now, the great, the *proved* evil of some of these schemes was the extent to which they had been made the subjects of gambling speculations. Men not worth a farthing had been put forth as subscribers to the parliamentary deeds, and holders of large interests, by others who obtained shares in their names, not choosing to risk their own names, and then sold the shares so obtained at a premium. This was a fraud upon the Standing Orders, which required that a certain and increasing proportion of capital should be subscribed before each House assented to the bill. Again, false representations were used as to the demand for shares, which made those shares, from the supply being considered inadequate to such demand, to rise to a premium. This was a fraud upon the public. Here were two frauds, one upon the Legislature, and the other upon the speculator, but both had a common origin, and could be defeated by a common blow. How easy would it have been to have enacted, that no shares should have been transferable, until acts of parliament were obtained, and that in the mean time, all transfers should be void or voidable at common law.

We have hinted at one remedy for acknowledged evils*; let us now look at remedies for other evils in the practice of parliament itself, not so much acknowledged, but nevertheless just as certain and injurious.

1st.—Why are the Standing Orders of the two Houses so inconsistent with each other, as to the deposit of plans, sections, &c., the Lords requiring such deposits to be made in November, and the Commons in the previous month of March?

2ndly.—Why do the Orders of the Lords require a deposit of only five per cent., those orders coming into operation in the later stages of a

* Every system of persecution, expense, and delay was resorted to, during the last session of Parliament, by the House of Commons, to prevent Railway Bills passing in the Standing Orders Committee, where the most trivial objections were allowed in rejecting bills for non-compliance of the new Standing Orders. In one instance, because a building (not included in the Schedule, nor intended to be included in the Act, nor required for the purposes of the Railway), coming within the range of 100 yards of the line of Railway laid down, was not shown at large, it was decided that it was a non-compliance of the Standing Orders; in another case, because a cow-shed was omitted to be shown at large, it was decided that the parties had not complied with the Standing Orders; in another instance, because there happened to be a border of shrubs surrounding a meadow, it was decided that it was a garden or pleasure-ground, and ought to be shown at large, consequently that bill was rejected; and several other instances of injustice could be pointed out throughout the different stages of the bill. And it is notorious, that the Parliamentary Agent who can muster the largest attendance of members, or count the *most noses* in his favour, in the Committee on the bill, procures the greatest share of business;—the practice from beginning to end is generally conducted in the most slovenly, unjust, and expensive manner possible.

bill, while those of the Commons require ten per cent. at much earlier stages?

3rdly.—Why is it necessary to repeat all the proofs before a Committee of the House of Lords, after they have been recorded by a Committee of the House of Commons, to the enormous cost of the suitors?

4thly.—Why are such enormous fees exacted as to be ruinous alike to suitors and opponents, and especially after the Courts of Law have reduced all their fees to a very moderate amount?

5thly.—What becomes of the money so exacted as fees? and why should private suitors be compelled to pay for the proportion of clerks and officers required for the public business of the country?

6thly.—Why should Members be allowed to vote on the preamble of a bill being proved, who have not heard a word of the evidence?

We shall add a few more queries in our next, and keep this important subject, as well as all the proceedings of Parliament on private bills, constantly before our readers.

OBSERVATIONS ON THE NEW HOUSES OF PARLIAMENT. BY MELA BRITANNICUS.

Sir,—Allow me, through the medium of your Journal, which bids fair to be of extensive utility, to raise one voice, however feeble, not only against the proposed plan of Mr. Barry for the New Houses of Parliament, but also against the site. Though not professedly an architect, the study of architectural works has occupied very many hours of my time during extensive travels through England, France, Italy, and Germany; and without vanity I may assert, that I have at least an experienced eye, and strengthened not a little my judgment. Without further preamble, I will state at once my reason for objecting to the site. Aware as I am of the great difficulties that invest all topics of this nature, I will couch my criticism chiefly in the interrogatory form. And in the first place, I ask with what view has the proposed site been chosen by the architect? Can any one be blind to its being one of the soottiest, lowest, and consequently dampest, that the metropolis affords? Is our veneration for the position of St. Stephen's, and the *infallible* wisdom of our ancestors, to supersede every other consideration? Why incur the heavy expense of a vast embankment, which the choice of a site remote from the Thames, consequently drier and healthier, would render unnecessary? Would it not be more plausible to leave the venerable Westminster Hall in the centre of three sides of a square, two of the sides presenting gable ends parallel with the end of the Hall, and in the first and simplest Gothic, devoting the Hall, and its environing appurtenances, to the gentlemen of the long robe *only?* Surely this will appear far preferable to the great majority of architects and amateurs to the plan proposed by Mr. Barry; for what a Babel of architecture must meet the eye from his huddling together the old Hall and new buildings, both of different styles!—Vitruvius ranks among the first qualifications of an architect the judicious choice of a site, in which, I fear, Mr. Barry, if his plan be adopted, will prove himself, or his employers (for architects have often this *salvo*) very deficient; for the fogs and smoke of London, the bane of architecture, brood in the site of the old Houses of Parliament as much as in the City itself. To diminish this disadvantage as much as possible; what position then would a happier *coup-d'œil* than that which the architect and his employers possess propose? Without pretending to declare it the best, I should select, as preferable, the site of old St. James's Palace,—a vile heterogeneous fabric, on the demolition of which no one, I guess, would write an elegy. The style should be Elizabethan, that being an order characteristically British; each of the Chambers to have two vast oriel windows looking towards the Park; the avenue to Buckingham House to be cut down; the whole building to be of stone; the interior of the House of Lords to be impannelled with Norway oak; the principal mouldings, with the roses and other ornaments in the ceiling, to be set off with the richest gilding. A similar plan might be adopted for the lower Chamber with less splendid ornament. The throne for our young and amiable Queen to be simply a chair of British oak, and of the richest Elizabethan form, with a simple velvet crimson cushion, and not presenting, as in the consumed House, a glittering and ridiculously expensive gew-gaw. The advantages of this site would be very great in reference to its contiguity to the New Palace, situated within two stones' throw; while the only disadvantage would be a five or six minutes' walk through Storey's Gate for the lawyers who might be summoned to attend either House. But this inconvenience would nearly be done away by having apartments annexed to the Houses for the reception of those lawyers who might be called to either House. Were this plan to be adopted, only consider the difference of the estimated expenditure. Two different estimates I have seen of Mr. Barry's project; one of £500,000, the other of no less a sum than 700,000 and odd pounds. With the fullest confidence I assert, that my three sides of the new square to enclose Westminster Hall, to be devoted only to legal affairs, would not cost more than £60,000, built of best brick, and faced, as would be sufficient both for effect and solidity, with four inches of best Portland stone, worked in the style of the earliest Gothic epoch.

I can, too, with equal confidence assert, that the sum of £440,000 would be sufficient, in the hands of an intelligent architect, to build in the first manner, and all of the best stone, the Elizabethan fabric, which he could arrange, with all its necessary appurtenances of library, record, committee, and waiting-rooms, for the above sum. Thus, if the estimate of 700,000 and more pounds be devoted to Mr. Barry's work, my St. James's Park and Westminster plans would be covered by the first estimate, viz. £500,000. But enough of objections relative to the site of the new florid Gothic Houses; proceed we to the reasons why I, and luckily for me, many hundreds of others, reprobate the style of Mr. Barry's plan. And first, I ask, did the architect and his controllers consider duly the nature of the English climate and atmosphere, before he or his employers favoured us with his florid specimen of Gothic? Did they turn their eyes to the condition of Henry the Seventh's Chapel, which, though thoroughly cleansed * some ten or fifteen years ago, has now nearly the same begrimmed complexion as its parental abbey? And what is the cause of this dingy hue, the bane of all delicate architecture for at least a six-mile radius from the centre of London? The neglect, I reply, of adopting the simplest style of Gothic, if it be to be adopted; though, I apprehend, that every wise architect would rather prefer, if not the Elizabethan, which has fewer mouldings, the Tuscan and Doric of Palladio, Scamozzi, or Vignola. But waiving further disputations on style, is it not extraordinary that the architect, having the example of the untoward effect of Henry the Seventh's Chapel before his eyes, should have persisted in giving us a plan of even richer Gothic, consequently presenting more nests for the deposit of the soot? Unfortunately, the London atmosphere is, of all others perhaps on our globe, the worst adapted for the exhibition of the delicacies of any florid style of architecture, and the last character of Gothic may be as plausibly reprehended for adoption, as might be the richer ornaments of the architecture of Asia Minor, or the Arabic of the Alhambra, or the yet more delicate chiselings of the Tâj-Mâl at Agra. It will be vain to refer, in answer to the authority of the wisdom of our ancestors, whose skill, though often to be praised, was as yet in its infancy, and who had much to say in vindication of their errors, seeing that London sent not forth in their time the ten-thousandth part of the volumes of smoke that it does now. I pretend not to criticise Mr. Barry's interior, not possessing the necessary data whereon to ground my judgment; but to return to the consideration of his exterior plan, I ask, what meaneth that centipedal tower, necessarily of exorbitant cost, with which he menaceth us? Towers, as authorized by Gothic architecture, are of two kinds, military and ecclesiastical. A tower attached to a castle we all feel to be in its element, as is a tower attached to a church, to serve as a belfry. Doth he mean that cannon should be pointed from it downwards to keep Radicals and Conservatives in proper order? If so, I object not, in an architectural sense, to his tower. Or doth he mean, that a belfry should be attached to it to summon our Queen and both Houses to their duty, a rope attached to a clapper above, and close to the Speaker's chair, to spare him the trouble of crying "Order!" If so, I know not that the tower is condemnable, unless it be in the triple view of its entailing a vast and useless expenditure, of being a very inconvenient receptacle for the records, and of its exterior presenting a mass of smoky blackness within ten years after its erection. I am aware that many may urge, in reply to my criticism, "Would, then, your Houses, built on the site of St. James's Palace, be free from smoke?" Not altogether, but in a much less degree, I answer, with the additional advantages of sparing the cost of the great embankment; of presenting a drier, healthier, and more cheerful place of rendezvous for both Chambers, and of being far more easy of access for our Sovereign, peers, and representatives.

Would not, I ask, a judicious architect renounce the site of St. Stephen's, not only for the above-mentioned reasons, but also from the consideration of the bad effect of so many vast edifices being cumbrously piled in the immediate neighbourhood? First, we have the old Hall, one of the largest in Europe; then comes, within a stone's throw, the old murky Abbey, from which the sweepers might collect at least one hundred bags of soot; within twenty paces of this stands St. Peter's Church, as untowardly situated as possible; a hundred yards behind rises the Westminster Hospital; and now we are to have the vastest Gothic pile ever conceived within a stone's throw of all these buildings!

Is it not extraordinary that the architect was unable to foresee that the sootty vapours must be accumulated in a tenfold degree more than heretofore, from the circumstance of such a multitudinous assemblage of piles being so closely huddled together, and necessarily diminishing the circulation of the air? that this confined contiguity must also reciprocally destroy the effect of each building? Have we not reason to wonder that the least experienced of the amateur commissioners should not have been struck by these conclusions? that they, as well as many members of either House, should have hesitated for a moment to open every battery of opposition to the adoption of the old site? "No, no," they cry, or in nearly tantamount words, "better be stoned like St. Stephen than abandon the site of his venerable chapel. Who cares whether a building be black or white? Destroy, indeed, the noble pile of St. James's, the favourite abode of our beloved eighth Henry; that fabric which attracts and fixes the eyes of all Europe, to make way for our new Houses of Parliament! As well might be proposed the pulling down of St. Paul's, or the new bridge of Waterloo."

But, Sir, it is useless to preach against the force of prejudice, more remarkable in this country, in many particulars, than in any other. Of this delectable element of mind John Bull has always quaffed his full measure; and had the wisdom of his ancestors decreed to fix the two Houses of his Parliament close to the foggy Whittlesea mere, and had a travelled person suggested sundry other spots more preferable, honest John would not fail to exclaim, "Whittlesea mere was ordained by my ancestors to be the eternal site of the Parliament Houses, so shall it remain." It is this same prejudice that blinds so many of us to the absurdity of the Thames Tunnel, a work which has been interrupted by three or four irruptions, which in a commercial view is comparatively useless, seeing the neighbourhood of the bridges; which impales with rheumatism for life, or subjects to drowning, so many clever workmen; which few will enter, if ever completed, but once or twice for curiosity; and

---

* It was re-cased with Bath stone.—*Editor.*

which, if by dint of vast labour it may be rendered at first tolerably free from dripping, cannot long remain so, from the percolating effect of the action and re-action of the tides; to a work, in short, which can confer no credit to the architect and his advisers, the primary error being the too inconsiderable descending curve. To return to the great question of the Houses of Parliament, wherein so many important considerations lie, perhaps something might be effected for furthering the adoption of a more advantageous site and plan, by those artists and amateurs who may side with me in opinion (and I know there are several), signing a powerful protest against the work in agitation, and submitting it through some Member to any future Committee. Let us hope, however, for the honour of sound taste and judgment, that the Commissioners have not irretrievably adopted this, in my opinion, highly objectionable plan of Mr. Barry. I know not the man, neither do I foster against him the least personal grudge. Let us hope, I repeat, that before final adoption, they have yet time to weigh most scrupulously every detail of a plan which involves so great an expenditure, and wherein our character as to discretion in a work destined for centuries, both in relation to our posterity and enlightened foreigners, is so eminently concerned.

MELA BRITANNICUS.

RAILWAY ACCIDENTS, BY AN OLD ENGINEER.

The extraordinary encouragement given to railway projects, upon the success attending that of the Liverpool and Manchester Company, of 32 miles in length, the confident anticipation that, to make the system one of universal adaptation, whether of locality or speed, was purely a matter of outlay and calculation, were the leading features of the speculative period of 1835. At that time it was expected, that as railway extension took place, railway science would improve with it, and that those new events, and new features which circumstances produced, would be met by corresponding mechanical expedients. Unfortunately, such is not the case; railways are now identically the same, with one exception, in construction and detail, with that of the Liverpool and Manchester. Is that perfect? If the accidents which are happening perpetually upon the various lines already open to the public be taken as the reply, it is one most decidedly negative.

Considering the costly nature of railway apparatus, it would seem the interest of railway directors to avail themselves of every contrivance by which their property would be secured. The destruction of a locomotive and train of five carriages would be a loss in value of upwards of 3000*l.* for the engine and carriages alone, without taking into account the loss of property for which the company may be liable, or the loss of life to the public; but it is a melancholy fact, within the personal experience of the writer of this article, that railway companies are decidedly opposed to any and every suggestion by which the system may be made safe, or generally improved, unless such suggestions emanate from their own engineer, a person who, in numberless instances, is noted rather for his influence than for his acquirements; and this observation particularly applies to the sub, or resident engineer, who, seven cases in ten, is the mere nominee of a powerful director, and if he be distinguished at all, it will only be in his profound ignorance of mechanical matters. A railway is essentially a mechanical enterprize, and no man ought to be entrusted with its management, unless he be well skilled as a practical mechanic. He ought to be a man of the most clear mind and profound judgment, a man capable of deciding at once whether a contemplated arrangement shall be attended with the desired result, not a man who can make a pretty report, or a neat drawing merely, or, perhaps, run down a level after a month's practice, but, in the case of a mechanical want, must run about to every forge and work-bench in the establishment before he is able to make up his mind, or select his measure. He ought to be, not a mere mechanic, but a man of invention, for so crude is the system at present, that to make it perfect and profitable, a man ought to be within call, ever ready with an expedient to supply wants as they arise. Men such as I have described are few, but they are to be found, and it would redound beyond calculation to the interest of railways, if the directors, in selecting their technical officers, were to cause them to pass a rigid technical examination before disinterested and skilful judges, with the same view as, in the medical and legal professions, a rigid examination is entered into before an applicant for honours is allowed to practise.

I have dwelt at some length upon this branch of the subject, because I have unfortunately observed, in some companies with which I am acquainted, the sad inaptitude of the parties in charge to conduct them, and it is the same thing to the public whether a railway is unsafe or irregular from a defect in the principle, or a defect in the management; and this want of confidence is beginning already to develope itself. I perceive by the public papers, that the lines of coaches which, upon the opening of the London and Birmingham and Grand Junction Railways, had discontinued running between London and Manchester, have resumed the road, so that the bitter fruits of their accidents will be severely felt by the Railway Companies mentioned.

The locomotive, a wonderful machine though it be, is still so complex and obnoxious to so many accidents, that it becomes matter of astonishment that it should have remained so long without improvement; but the same causes operate in this, as in the cases before stated, in the discouragement given by railway directors to railway improvements. A railway company, if a projector were to place upon their line a better locomotive than they already possess, would perhaps buy it; but they would go no lengths, in a pecuniary way, in assisting a poor but clever man in bringing forward any contrivance he may propose; neither would they protect him from the enmity which would be felt and manifested by their own mechanical agents, towards his contrivance when produced. Thus it is that corporations are, in their very constitution, inimical to scientific improvement; and although the enormous funds at their disposal provide them with the means of encouraging the art to an extent wholly beyond the power of individuals, nothing is to be hoped from them; and whilst they remain as at present constituted, the probability is, that the system will retrograde, or be perhaps at last abandoned by the public in disgust. In order, however, to avert such a state of things as far as my knowledge goes, I shall point out the causes and means of avoiding the accidents which occur so frequently.

It is an usual reply to any question raised as to the cause of an accident, that the fault is in the man in charge, or that some malicious person places stones, wood, or a bar of iron across the rails. The first cause is almost always the wrong one, for the engineer has so evident an interest in avoiding an accident, that he must be a madman to cause it; but an engine and train ought to be constructed in such a way, and provided with such apparatus, as either to forbid the possibility of accidents, or when they do occur, they may be, in their consequences, harmless, and easily set to rights. In the event of an engine running off the line, means ought to be at hand speedily to replace it, and the carriage or frame of the engine and carriage so formed, as to remove impediments placed accidentally or by design across the rails; in fact, the antennæ of insects point out the remedy. If a frame were hung in front of the engine to within a very short distance of the rails, say two inches, with an apparatus at the command of the engineer to lower it, at night, or when he perceives by day any thing likely to impede his progress, the stones and timber which cause so much mischief now, might be removed or swept off by the engine itself.

In the construction of the carriage, the principle to be adopted ought to be to bring down the centre of gravity to the lowest point possible, thus making the carriage safe under all circumstances. The load, by being hung low, produces less draught upon the engine, because it approaches nearer the line of traction, viz., the surface of the rails; and linking the trains below the axle produces a valuable mechanical advantage in favour of the engine, that the load tends to assist the adhesion of the driving wheels. The system of linking, adopted upon the London and Birmingham, and other railways, is most vicious. On those lines, the carriages are screwed up until the buffers touch hard, so that they have a tendency in all cases to keep straight. Thus in going round the curves, the rigidity produced from this arrangement will act in unison with the centrifugal force, and tend to throw the carriages off the line. The action is, in fact, that of a cane, that has always a tendency to return to its original position. It is true that this screw apparatus prevents the shock of the carriages, which is so annoying when they are yoked only by chains; but in order that one difficulty may be avoided, another much worse is fallen into. In order to accomplish this object in a scientific manner, a drag spring ought to be fixed to one end of the carriage, and a buffer spring to the other; thus, when the carriages are placed in line, a drag spring and buffer spring are opposite the one to the other. These two springs, united by a double joint, leaves all the flexibility required for the curves, and the elasticity, with the absence of jolting, required for the carriage.

The form of the chair is also an object deserving much attention. A chair ought to be as little wider than the rail as circumstances will admit, for in the case of the engine running off, if the wheel should strike against a chair, such as those of the London and Birmingham line, the concussion would be dreadful, and it would throw the engine round, as happened lately upon that line. The fact is, when there is no chair or other obstacle in the way, and the ballasting carried within an inch or two of the top of the rail, no harm would arise from the accident, because the velocity of the train would be arrested gradually, by the engine wheels being opposed to a medium, producing greater resistance to their progress than the rails themselves, unless crossing an embankment, where if the embankment be very narrow, or not provided with a parapet, it is probable the engine might run down the bank, and drag the train with it.

I have seen an engine after it has run off the line, the wheels of which were scrated all round by running over the feet of the chairs, and it must have gone a distance when off the line fully equal to three revolutions or fifteen yards. Had there been these chairs, such as those on the London and Birmingham line, and like those exposed, the engine would in all probability have been dashed to pieces, and the train too.

The switches are a most important appendage to a railway. The best switches which have been yet offered to the public, are those invented by Mr. W. S. Curtis, first introduced upon the Greenwich Railway. In these switches the angle is lost, so that a train passes through them with as much smoothness as along the line. This is effected by forming the switch for the outside line of the curve double, one bar straight for the line, and the other curved to correspond with the diagonal. The inner switch may be likewise double; but it is better to form it with a pointed switch, in the common way, and a fixed rail. This produces a lighter apparatus, and the inner or passive line, it is of no consequence whether formed with an angle or not. Care must be taken to make the lever and balance weight in such way that it may be always right for the line. In laying out a railway, provision should always be made so that at the various stopping places the engine and train may draw out of the line, and leave it unoccupied, so that the line be always open. Had this precaution been taken, the fatal accident which happened in the Grand Junction Railway, some time past, would have been avoided.

Such is the anxiety, certainly pardonable anxiety, for railway shareholders to commence business, that the works are frequently hurried, and operations begun before the various embankments have had time to consolidate. I would recommend, as a sincere well-wisher to railways, that a little forbearance should be exercised, and the embankments allowed to remain until they have been well saturated with rain, and thus frosted, before the line is opened to the public. This forbearance will be well repaid, by the satisfactory and regular operations of the line afterwards.

AN OLD ENGINEER.

THE SOANEAN MUSEUM.

"Nessuno l'obliga a far questa cosa, e se la fa, la dee fare grandiosamente, e non con sordidezze e spilorcerie."—Mota.

In defiance of the proverb which cautions us against looking a gift horse in the mouth, we cannot forbear looking at the Soane donation to the public, in doing which we can hardly be accused of prying into matters that do not at all concern either ourselves or our readers. Neither can we look at it long before discovering that, so far from being, as some have chosen to style it, a "munificent and patriotic bequest to the nation," it is the mere mockery of one, a most notable piece of show and delusion,—a gift wherein the donor evidently consulted his own vanity more than any thing else, and at last bestowed it so ungraciously and parsimoniously as to manifest the very reverse of a generous or even a loftily ambitious spirit.

As to the house itself, it is generally well known to have been Sir John's favourite hobby; and from first to last he probably expended upon it as much as would have sufficed to rear a mansion and galleries four or five times the extent of the present building. In fact, independently of the gallery which extends behind that and the adjoining dwelling, the house does not at all exceed a moderate-sized one, with two drawing-rooms on the first floor. In making this observation, however, we do not deny that it exhibits much ingenuity and many contrivances, very clever in themselves, as ideas and hints—but at the same time a great deal that borders upon meanness and insignificance—much that partakes of littleness no less than of whim, with much also that looks no better than a temporary experimental trial or model of what was intended to be executed on a larger scale; for at present, not a few effects partake far too much of the petty and the peep-show. Indeed we are much more frequently and more forcibly reminded of the latter than there was any occasion for, by the ridiculously pompous names bestowed on mere closets and other confined spaces; some of which, we could almost imagine, must have been given in derision and burlesque. In regard to the collection itself, there is very little indeed in it to entitle it to any kind of distinction, if we except the Belzoni sarcophagus, and the Hogarth paintings, since the rest consists chiefly of architectural casts and very mediocre pictures; the former so huddled together as to convey quite as much the idea of a dealer's show-room, as of a museum. Neither can it be said that the collection of books is either a very choice or an extensive one. As one of works of art, it sinks into absolute nullity compared with that of the late Count Cicognara, and is, we believe, in very many publications that are to be met with, not only in the libraries of the opulent, but in those of much humbler purchasers, who, we must henceforth suppose, deserve credit for partaking of that enthusiasm and liberality which was so bountifully attributed to Sir John Soane.

Still, let the collection be what it may, the public would have reason to be grateful for it, and to bid it welcome in spite of all its imperfections, had it not pleased the "munificent donor" himself to lay a 'touch not,' 'taste not' embargo upon it, placing those, who might be disposed to avail themselves of it, in the situation of Tantalus. How stands the case? Why, after the ostentatious parade of an Act of Parliament, securing the bequest to the public, but leaving him at liberty to impose such conditions and regulations as he might afterwards think fit, he, all but nominally, rescinds it; because, as it now appears, the public are to be admitted only a few hours on twenty-four days out of the three hundred and sixty-five; or, it may sometimes happen, not even half that number, fine weather being as indispensable a passport as a ticket! So that between the caprice of Jupiter Soane and that of Jupiter Pluvius, the public are not likely to wear out their eyesight in gazing on the treasures of art which are doomed to remain incarcerated at No. 13, Lincoln's Inn Fields!

So far, then, from there being any thing of liberality or graciousness in such a gift, although we admit it to have the merit of being admirably characteristic of the giver, it can hardly be described as any thing short of over-reaching the public, first getting ready payment from them in praise and puffery, and then putting them off by a species of paltering and juggling—or, if such reading be preferred, paltry juggling,

> That keeps the word of promise to our ear,
> And breaks it to our hope.

In prospectu the donation was liberal enough: in reality, it turns out to have been dictated solely by selfish vanity, and by an ambition truly mean-spirited. Why! the griping usurer who builds and endows an almshouse, acts princely in comparison with a begrudging stinginess, which is all the more disgusting because it cloaks itself up in the garb of pompous generosity. It is no apology for Sir John to say, that as the public had no claim upon him at all, they ought to sit down contented with the very miserable pittance they have got, notwithstanding it falls so far short of what they had at one time reason to expect. We think very differently; no one, indeed, is bound to invite another to an entertainment, but having done so, he is most certainly bound not to slam the door in his face when he arrives. And whether the door of the Soanean Museum may not very fairly be said to be, if not exactly slammed in our faces, kept padlocked and barricadoed against us, we leave our readers to decide, after what has been above stated in respect to admission.

None can be more ready than ourselves to admit that the house in Lincoln's-Inn-Fields is as ill-suited for a place of public rendezvous of any kind as can well be imagined; a score of people make quite a crowd in it, and even one, supposing him to be of portly dimensions, must work his way as gingerly through the gimcrackery and its defiles, as he would through a fashionable 'squeeze.' Yet this becomes only a *raison de plus* for its being opened every day (Sundays excepted) throughout the year; and if not all day long, at least as long as daylight lasts. Instead of which the grudgingly bestowed pittance of twenty-four days must always be more or less curtailed by wet, or, it would seem, even dirty ones; for we suppose Sir John died too poor to bequeath a fund for purchasing mats and scrubbing brushes. We grant, that in case of its being so opened, it could not very well be retained as a private residence. What then? If it was to be public property, it was the convenience of the public, and that alone, which ought to have been consulted; on the other hand, if it is to be in reality private, why was it not kept so, without any 'make believe' and child's-play nonsense of bestowing it upon John Bull?—though we grant that it may with some plausibility be argued that a fictitious gift is a very suitable one for a fictitious personage, which reflection, perhaps, quieted the conscience of John Soane when he thus choused the other John. His donation is, like Dame Quickly, neither fish nor flesh—a mere 'dog-in-the-manger' affair, which gives in good earnest to no one, neither the public nor any other party. Except in words alone it no more belongs to the former, than do the galleries and collections of private individuals, who set apart days for letting them be seen by tickets, which, after all, is not considered a very portentous stretch of generosity or public spirit on their part.

Had Sir John actually been the public-spirited character some exceedingly credulous people have imagined, and some very fawning ones represented him to be, he would have consulted his object more effectually by bequeathing his collection as the nucleus of a museum of architecture that should be constantly open to the public, professional men, and students. He might thus have laid the foundation for a national establishment of the kind on a most liberal footing, and extensive scale. Even this, though a welcome and *bonâ fide* donation, deserving our gratitude, would have been no prodigy nor unparalleled example of prodigal patriotic munificence, when we call to mind the magnificent church of Possagno, erected at his own sole cost by Canova; or the Fitzwilliam bequest; or the generous, though little spoken of, liberality of the Dublin architect, Francis Johnston, who with a more princely feeling, if not with so princely a fortune as the English one, did not wait for his departure from the world, but during his lifetime reared a handsome building for that purpose, and presented it to his brother artists! But *Dis aliter visum est*, the Soane donation is a mere farce, what would vulgarly be styled *a dead take in*; and it will go down to posterity as a monument of the knight's selfishness, his caprice, his paltry vanity, his sordid pomposity, and his double-dealing, unless it should please posterity to consider him more indulgently as a well-meaning dotard.

Pro Patria.

ENORMOUS STONE REMOVED FROM THE RIVER TAY, IN PERTHSHIRE.

The improvement of the navigation of the Tay is going on under the superintendence of the Messrs. Stevensons, of Edinburgh, who, before recommending the docks being made at Perth, advised, as a preparatory work, the removal of the different fords and sandbanks which have always obstructed the navigation, as well as the formation of certain junction dykes, which, by joining several islands with the main land, thereby contracted, straightened, and deepened the principal fairway of the river. Some hundred thousand tons of matter have already been removed, and part of the excavation for the Perth harbour is also completed. Some years ago a large stone, yclept *Craig Sharpie*, was removed from the bottom of the Tay, which had frequently caused damage to the shipping. Mr. Turnbull, the resident engineer, received much credit for the success of his undertaking at the time; but he has achieved a much greater feat lately. An immense stone, long supposed to be a rock, and embedded in the fairway of the channel, about 200 yards from the Friarton, the top of it being immersed to the depth of five feet at low water, has been removed from its situation by operations continued during only five tides. From the efficiency of the means adopted, it was raised and taken ashore on the Friarton Island with comparatively little trouble, although its weight is between forty and fifty tons, and its solid contents, 12 feet 3 inches long, $7\frac{1}{2}$ feet broad, and $6\frac{1}{2}$ feet thick=598 cubic feet.

The way in which the stone was raised was by means of two dredging lighters, capable of containing 25 tons each; these were brought to the spot at low water, and a hole of two inches diameter having been previously made in each side of the stone, and plug bats having been inserted, a chain was fastened to them, and when the tide rose the stone was floated off its bed and thus conveyed ashore. The specific gravity of a similar whinstone block was formerly ascertained, from which it was found that eleven and a half cubic feet equalled a ton. Eighteen cubic feet of the gravelly matter from the bottom of the river have been found on an average to weigh a ton.

CANAL LOCK, GATE, PADDLE, OR CLOUGH.

Sir,—I beg to forward for insertion in your excellent Journal, the following facts as to the effects of two new Paddles or Cloughs, constructed on a new plan, and applied to one of the locks (Bradley Lock Upper Gates) on our canal. The lock is 76 feet long, $17\frac{1}{2}$ feet wide, the recesses for the lower gates (each) 12 feet by 9 inches, and the fall 5 feet, making 6740 cubic feet, or $46,243\frac{3}{4}$ gallons of water to each lockful.

The lower gates being closed, and the new cloughs in the upper gates drawn, the gates will open in less than one minute (54 seconds) from the commencement of drawing the cloughs. The *handling balances the clough when up.*

The clough descends (after a slight push with the hand) by *its own gravity* without any perceptible *concussion upon the lower bar of the gate*, and it is raised with ease when the lock is empty by a man at the handling, which describes a radius of 18 inches.

I forbear making any remark upon this *very simple* and *effective contrivance* at present, but at some future time I may forward to you a sketch, a drawing of one gate, with the clough, &c., annexed. Yours, &c.

Engineer's Office, Winwick Quay, November 10, 1837.

John Lister, Engineer to the Sankey Canal Company.

[We shall be obliged by having the drawing forwarded to us for insertion in our next Number.—*Ed. C. E. and A.*]

BRICK AND CEMENT BEAM.

Sir,—Observing an account in your last Number of the brick and cement beams which have been lately constructed by Mr. Brunel, and by Col. Pasley, of the Royal Engineers, for ascertaining the strength of materials and their aptness for certain novel applications, I beg to mention an extraordinary example of the kind, which stands exposed by the way-side on the road leading from Vauxhall to Battersea Fields. Passing in that neighbourhood a few days since, to ascertain the London terminus of the Southampton Railway, I found an erection on a plot of ground, which that Company has selected for the purpose of a depôt, exactly opposite the Cement Manufactury, Nine Elms, which is described by a board affixed as an "Experimental Brick Beam."

This erection is a brick wall 24 feet 6 inches long, 4 feet 9 inches high, and 2 feet thick.—Between its second and third courses from the bottom, two parallel lengths of slight iron-hoops are inlaid, the ends of which are seen projecting; in the fourth course from the bottom, the hoop-irons are again visible at each end; and above that, between courses seven and eight, there appears only a single length of the iron, in the next course after which there is none. The wall is raised six feet from the ground, each end resting on a pier of brickwork, the *length of twenty-one feet four inches clear between the piers, being without support*, under which you may walk as under a wooden beam! This I consider a surprising proof of the strength of adhesion of Roman Cement: you will observe, that more than double the length of the brickwork in the experiments mentioned by Colonel Pasley is here unsupported. But this is not all; by a chain, or some other contrivance thrown over the wall at its centre, a cradle is suspended, loaded with pig-iron, and on which is inscribed the weight it contains, viz., 10 tons 14 cwt. 1 qr. 4 lbs.

If there had been the slightest elevation of the centre of this structure forming any segment of a circle, or were there now any depression from the prodigious weight appended to it, there would be an evidence of settlement in the joints of the brickwork, or more probably of fracture in the bricks themselves; but this is not to be discerned; it is a perfectly horizontal brick beam, stretched as it were, from pier to pier, over a space of twenty-one feet, supporting nearly eleven tons on its centre.

It is not for me to point out the practical advantage that may be derived from this curious experiment; I would recommend all scientific persons, to whom it is accessible, to see it, which they may do in riding past, and I should think the application of its principle, in a vast variety of instances, must suggest itself to them. Your's, &c. A. C. E.

Essex Street, November 17, 1837.

[This beam, loaded as described, has now been standing, to our knowledge, without any appearance of fracture, for nearly two years.—Editor.]

PARISH SURVEYS.

Sir,—The vast number of surveys which are now being commenced for the Poor Assessments and Tithe Commutations, would seem to be likely to call forth, ere long, the whole body of surveyors into the field. It would behove all those who are undertaking heavy contracts, to beware that they are not losers by the lowness of the prices at which they are agreeing to take them—and parish authorities should also be careful that they intrust their surveys to competent professional men—not, for instance, to London map-sellers.

All the surveys are, when completed, to be placed under the surveillance of the tithe commissioners, or their assistants, who require every parish to be triangulated. I would remark that this triangulation, which is entirely extra to the surveying, will alone cost about two-pence per acre; when the survey is completed, the acreage is calculated, the books of reference compiled (all, moreover, in a much less space of time than ought to be allowed), and when all assistants and labourers are paid, where will the professional man find the reward for the sweat of his brow? I am far from impugning the rules which are circulated by the Tithe Commissioners, but I do think that parties, undertaking and guaranteeing surveys by contract (like bricklayers), and in ignorance of what the Commissioners require, will find themselves, at the present prices, finally much out of pocket. The vastness of many of these surveys, and the accuracy required, would seem to call forth the talents of many who have hitherto thought surveying beneath their notice, I mean the younger members of the profession of civil engineering; but it would be painful to see members of a profession of high standing, undertake business at a price which would barely remunerate a country schoolmaster.—Your's, &c. W. R.

THE DUTIES WHICH PROPERLY DEVOLVE ON THE CIVIL ENGINEER, AND ON THE ARCHITECT RESPECTIVELY.

Mr. Editor,—The object of your Journal being the advancement of science, and the improvement of the public taste, I do not hesitate in calling your attention to the importance of a just discrimination between the duties which properly devolve on the Civil Engineer, and on the Architect respectively, from a neglect of which at the present time there is great danger of the public interest being often seriously compromised; the want of judgment in the selection of professional advisers frequently manifested by Directors and Committees, shows that they cannot be aware of the great difference between the education and course of practice which distinguishes the two professions.

I am persuaded that from this circumstance many of the architectural structures, connected with the numerous rail roads now forming, instead of being in accordance with the improved taste exhibited in the architecture of the metropolis, and in most of our provincial towns, will rather resemble the buildings of an union poor house, or those surrounding the press yard of a prison, than the public works of a great and wealthy nation. Perhaps it may be argued, in extenuation of this neglect of taste, that the *minor* stations of a rail road are too insignificant to be placed under the direction of a regularly educated architect, and that they may therefore be left to the taste of a clerk in the engineer's office; but surely if the park lodge, the turnpike house, or the village inn, are susceptible of an architectural character, a rail road station cannot be less so; and in proof of this position I would, amongst many other examples which might be cited, refer to the neighbourhood of Trentham, where no traveller can fail to be struck with the taste displayed under the directing hand of the late Duke of Sutherland, in all the road side buildings on his estate.

As much of the picturesque scenery of our country, and the numerous mansions of our nobility and gentry, with which it is so thickly studded, must in a great measure be lost to the rail road traveller, any suggestions for supplying objects of interest along the line of road, cannot be undeserving the attention of those who have the direction of these undertakings.

I would merely add, that on the score of expense, it is well known to those who are conversant with such matters, that a heavy unsightly structure is frequently more costly than one which would combine beauty with utility, or picturesque effect with every requisite accommodation, I am persuaded that no engineer of eminence will hesitate in admitting that the character of the works chiefly occupying his attention disqualify him for entering into those minute details, on which architectural beauty is so dependent, and he will therefore gladly transfer this department to one whose education and habits of thought qualify him for doing it justice.

With best wishes for the success of your valuable Journal, I remain, Mr. Editor, your obedient servant,

November 18, 1837. AN OBSERVER.

SUGGESTIONS FOR A MONUMENT TO WILLIAM CAXTON.

Sir,—As a survey is now being made for the purpose of building a new line of street from Pimlico to the new Houses of Parliament, permit me to suggest the propriety of erecting a suitable monument to the memory of Mr. William Caxton. The memory of the man who first introduced the art of printing into this country, ought not, surely, to be totally neglected; and as the Almonry, where his house still stands, in which he erected his first printing press, will, no doubt, be pulled down, a most favourable opportunity is thus offered—to neglect which would be most unpardonable.

On the site of the Almonry a square, bearing his name, might be erected, in the Tudor style, surrounded by a cloister, in the centre of which his statue might be placed, and on one side a Government printing-office might be built, with a tower and spire, conspicuous above the surrounding buildings.

The style of architecture that I have ventured to suggest, being that which was practised in the age in which he flourished, would, I conceive, be most appropriate.—Your's, &c. A. J.

November 16, 1837

MR. BARDWELL'S COMMENT ON REVIEWER OF "TEMPLES, ANCIENT AND MODERN."

Sir,—Luckily for me I possess a shield against which the bird-bolts of your Reviewer fall harmless. If he had read my prospectus attentively, he would have seen that the work therein described "will comprise a digested collection of upwards of 800 notes, made for the guidance of the author in his professional practice." Your Reviewer pretends to have seen this prospectus, but why did he overlook this paragraph, which renders his tirade of abuse both unnecessary and ridiculous? Moreover, his discourtesy prevents my giving the very easy explanation of the plate of St. Mary, Woolnoth, or the reasons why the lancet-arch-style of architecture accords best with the lofty spire. But, thank heaven, his venom is innocuous—resembling an over-dose of arsenic, instead of poisoning, it sickens.

That your Reviewer should see no connexion between the illustrations and the text, is not at all surprising in one who could see no connexion between the figure of the stone-mason and the

"Oppida Publico,
Sumptu Jubentes, et Deorum,
Templa novo decorare Saxo"

of Horace.

Satisfied with the good intentions with which I published my "Notes on Church Architecture"—satisfied with having produced a work containing more information upon one particular subject at a smaller price than any work of the kind ever known—satisfied with the great and unexpected circulation the work has obtained among architects, and the unanimous declaration of those gentlemen, "that there never was a work calculated to do so much good for the profession," I take leave of your Reviewer, knowing that it was such anonymous scribblers as he, that imbittered the life of a *Chambers*, and caused the premature retirement of a *Soane* from a beloved profession which he adorned.

And now, Mr. Editor, permit me, as a well-wisher to your Journal, to caution you against admitting into your pages, without due examination, the productions of these shrouded stabbers, however low the price may be at which their effusions are offered, particularly when their opinions are the reverse of your own, as witness the contrast presented in the first and second numbers of your periodical. A "Civil Engineer and Architect's Journal" could hardly be expected, at its outset, to heap ridicule upon its supporters, from the highest to the lowest, as the respected name of *Gwilt* among the former, and that of my humble self among the latter, fully evidence.—Your's, &c.

49, Pall Mall, 4th November, 1837. WM. BARDWELL.

In courtesy to Mr. Bardwell (whom we consider a highly respectable member of the profession) we give insertion to the above letter, but we must beg it to be strictly understood, as not forming a precedent. We must suppose it

is intended rather as a piece of admonition to us, than a justification of himself. That the article was far from being favourable towards him, we admit; that the censure was in any respect unjust or unmerited, his letter does not prove; on the contrary, the only thing wherein we were mistaken, was in imagining that the work professed to be an original one, instead of a mere compilation of notes selected from different sources, which, he says, the Prospectus would have given us to understand. We can only say, that it would not have been amiss had he distinctly stated in the book that such was its plan. In our opinion, too, it would have been no more than fair both towards us and those from whom he borrowed, had he given a list of the publications he had availed himself of, with reference to the pages where passages from them occur, unless pointed out in the body of the work itself. At present, it is impossible to know exactly what he has borrowed, and what is really his own; besides, by expressly quoting one or two works, the inference is that he wished all that was not so quoted to pass for his own. With the success of the work, the high character it has already obtained among the profession, and the opinions pronounced upon it by the rest of the press—does he include that of the *Atlas?*—he assures us he is perfectly satisfied. Unless, therefore, he attaches more importance to our review than all the others put together, we do not see what he has to complain of. Most assuredly we do not see wherefore he should remonstrate with us. *If the critique in question betrays ignorance*, coupled with injustice, if it has censured when it ought to have praised, it can hardly be so formidable as to shake the high reputation it had previously acquired, it seems, among those who ought to be competent judges of its worth. It is we, rather than Mr. Bardwell, who must lose in the estimation of the public.

We thank him for the solicitude he expresses on our account, and for the caution he recommends us to adopt for the future; the plain English of which is, that in our reviews of books we ought to say nothing likely to be at all unpalatable to their authors. How this is to be reconciled with our duty to our readers, he has not informed us. We have only one other brief remark to make, which is, that Mr. Bardwell has fallen into a most ludicrous mistake when he cites Sir John Soane as a victim to ill-natured, envious criticism, saying it caused him to retire *prematurely* from his professional career!!!—*Editor*.

COMPETITION ESTIMATES.

The following remarks upon the system of competition estimates, for works about to be performed, are rather hurriedly thrown out; but thinking the system is bad under any circumstances, I do not like to delay giving vent to my ideas, although having other engagements, than by committing those ideas to writing. I must be excused if I do not enter quite so fully into the subject as I know many would wish. There are several different modes of competition: the worst and most unfair is the common way of advertising, the plans and specifications to be seen generally at the Architect's or Surveyor's Office, when parties must be at great trouble, if not expense, to take out the quantities, &c. I have known nearly one hundred pounds expended in this way, and the job lost after all. Another most unfair method is advertising as before, and when parties apply to take out the quantities, &c., they are informed they will have them furnished on payment of a certain sum, thus taking perhaps fifty pounds from the tradesmen, when the sum charged to one would have been ample; this plan was adopted to some purpose (!) (report says to the tune of thousands) by an ingenious young Architect,* during the time workhouse building was at its height, a number of which he contrived to have a finger in. Another and certainly much less objectionable plan is, writing to several tradesmen, and then for them to appoint some person (generally a respectable Surveyor) to take out the quantities for the whole, the parties carrying out their own prices, and the winning party paying the person who took out the quantities, thus bearing the losers free of expense. Again, a still better method is for the Surveyor himself to furnish the quantities to all, of course the winner still paying for them; in the two last methods, the charge for quantities should be furnished with them. Another, and in my opinion the best method, is that in which different descriptions of work given, and a price per foot, yard, rod, or whatever it may be, is required, the work when done being measured and charged at those prices; but even this is objectionable, as I shall endeavour to prove. It is very common with many people to say, "give a good price, and you will get a good article;" with nothing does this saying hold good more than building; you may have cheap houses, as well as other things, but that is no reason why they should stand the test of cheapness—durability.

The system of having works competed for by various parties, can have in the end but one effect, namely, that the works, of whatever description, are not done in that "sound, workmanlike manner" that they would have been, had but one party been applied to for an estimate, or had the work been done by measure and value, which, in my humble opinion, is the only correct method. It is a well-known fact in the trade (I mean building), that contract work is never done any better than can be helped, if I may be allowed the expression, as all that the Contractor cares for, is to obtain the Surveyor's certificate of the work being completed. After gaining the contract, the whole object is to get the work done, no matter how, and as cheaply as possible: thus inferior workmen (so they can but get over a good deal) and materials are very often employed, notwithstanding the vigilance of a Clerk of the Works, Surveyor, or whoever may have the superintendence of the work. I am fully aware of the serious charge I am now making, and that the answer will, in all probability be, that no respectable builder will do such things. Those who say this, should think of the saying, "[illegible] is roguery in all trades but ours;" and let them inquire amongst working men, and the answer will be, that as long as the work is done, it is of no consequence how, so that it will but pass. I am aware, also, that in ninety-nine cases in every hundred, no directions to this effect are given by the Contractor; but why is this? simply because it is perfectly understood by working men, that contract work is not expected to be finished in that "sound, workmanlike manner," that other work is, at least not by the Contractor. If I were requested to prove these assertions, by reference to works already done, I fancy most who read this would be able to point to some public or other building, whose tottering state would fully bear me out. Indeed, while writing this, several seem to arise to my memory; but as it would be invidious to name them, and might lead to much discussion, I shall refrain. What is the general excuse made, when any one remarks that there is a great deal of settlement in such a building (naming one), or that the joints of the flooring or other wood work open very much, that the plastering blisters, and the enrichments are not well relieved; or, in fact, whatever fault you find with the work, what, I repeat, is the excuse made? *"Oh, it is only contract work."* Yes, "only contract work;" and yet, in the face of this, contract work is on the increase; indeed I may say that nothing is now done without competition. It is but about a month ago that three different parties were written to respecting a slight repair, that did not amount to a sovereign altogether: this was perfectly ridiculous, but not less true on that account. I shall not enlarge further upon this subject at present, for the reasons before stated, hoping what I have remarked will lead some one more able, though not more convinced of its evils, to endeavour to effect the disuse of the system. Much more might be said, something perhaps in its favour, but let many, very many insecure buildings and ruined tradesmen speak for themselves. Allow me to add, that it is a system that leads to much dissimulation and bad feeling, engenders envy, hatred, malice, and all uncharitableness.

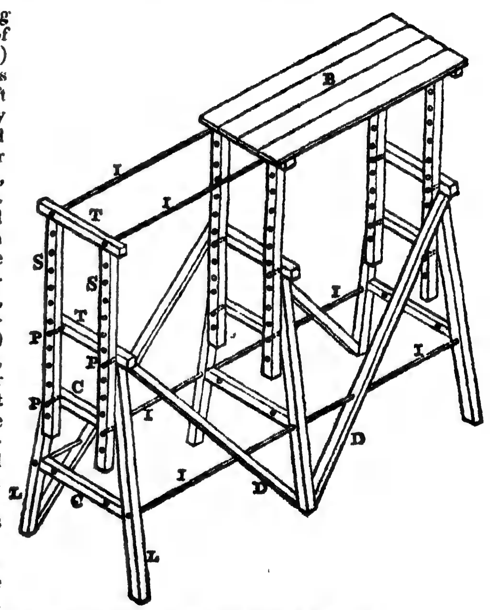
November 20, 1837. J. J.

* If such an occurrence did take place, it is one of the most disgraceful acts that any man could be guilty of. If true, we should be glad to receive the particulars, that the party may be held up to the scorn of the respectable portion of the Profession, who, we are sure, will join with us in condemning such a system of robbery —EDITOR.

BIELEFELD'S PORTABLE SCAFFOLD.

THIS Scaffolding consists of a series of frames or horses (L L) upon which others (S S) are made to shift up and down to any required height, and secured to the lower frames by iron pins, with nuts and screws.

The upper and lower frames are each 10 feet high, the scantlings of the timbers 3½ inches by 3, and connected together by iron rods (I I) one inch diameter, having a shoulder on one side, and nut and screw on the other, and kept upright by diagonal braces (D D), as shown in drawing.



The upper frames are 3 feet wide, with top-rails 4 feet long. The lower frames are 3 feet wide at the top, and spread to 6 feet wide at the bottom, with top-rails 4 feet long.

The posts of the upper frame (S S) are strengthened on each side by plates of iron, an eighth of an inch thick, and perforated with holes for the pins to pass through, about 9 inches apart. The other timbers have an iron plate on one side only (excepting the diagonal pieces).

The board (B) can be placed at any height, either on the top-rails (T T) or cross-rails (C C), so that two or three stages can be formed at one time upon the same scaffolding. The whole is made to take to pieces, the several posts and cross-rails being morticed together, and secured by nut and screw-bolts. It is evident that any number of these frames can be made to form a scaffolding of any extent, and where only a low scaffolding is required, the upper frames can be used, as well as the lower, for the same purpose. The whole can be put up or taken down with the greatest facility.

The above was invented by Mr. Bielefeld, for the purpose of fixing his *Papier Machée* ornaments upon the walls and ceilings of large rooms; and he is now preparing one, of some extent, for the works he is executing for the long galleries of the British Museum.

We recommend the use of this scaffolding, not only for its portability and facility of fixing, but for the greater security against those accidents that so frequently, and, lately, so fatally, occur to scaffolding of the common description. Among other advantages are its neatness of appearance, and economy of room in construction, which in finishing interiors is very desirable.

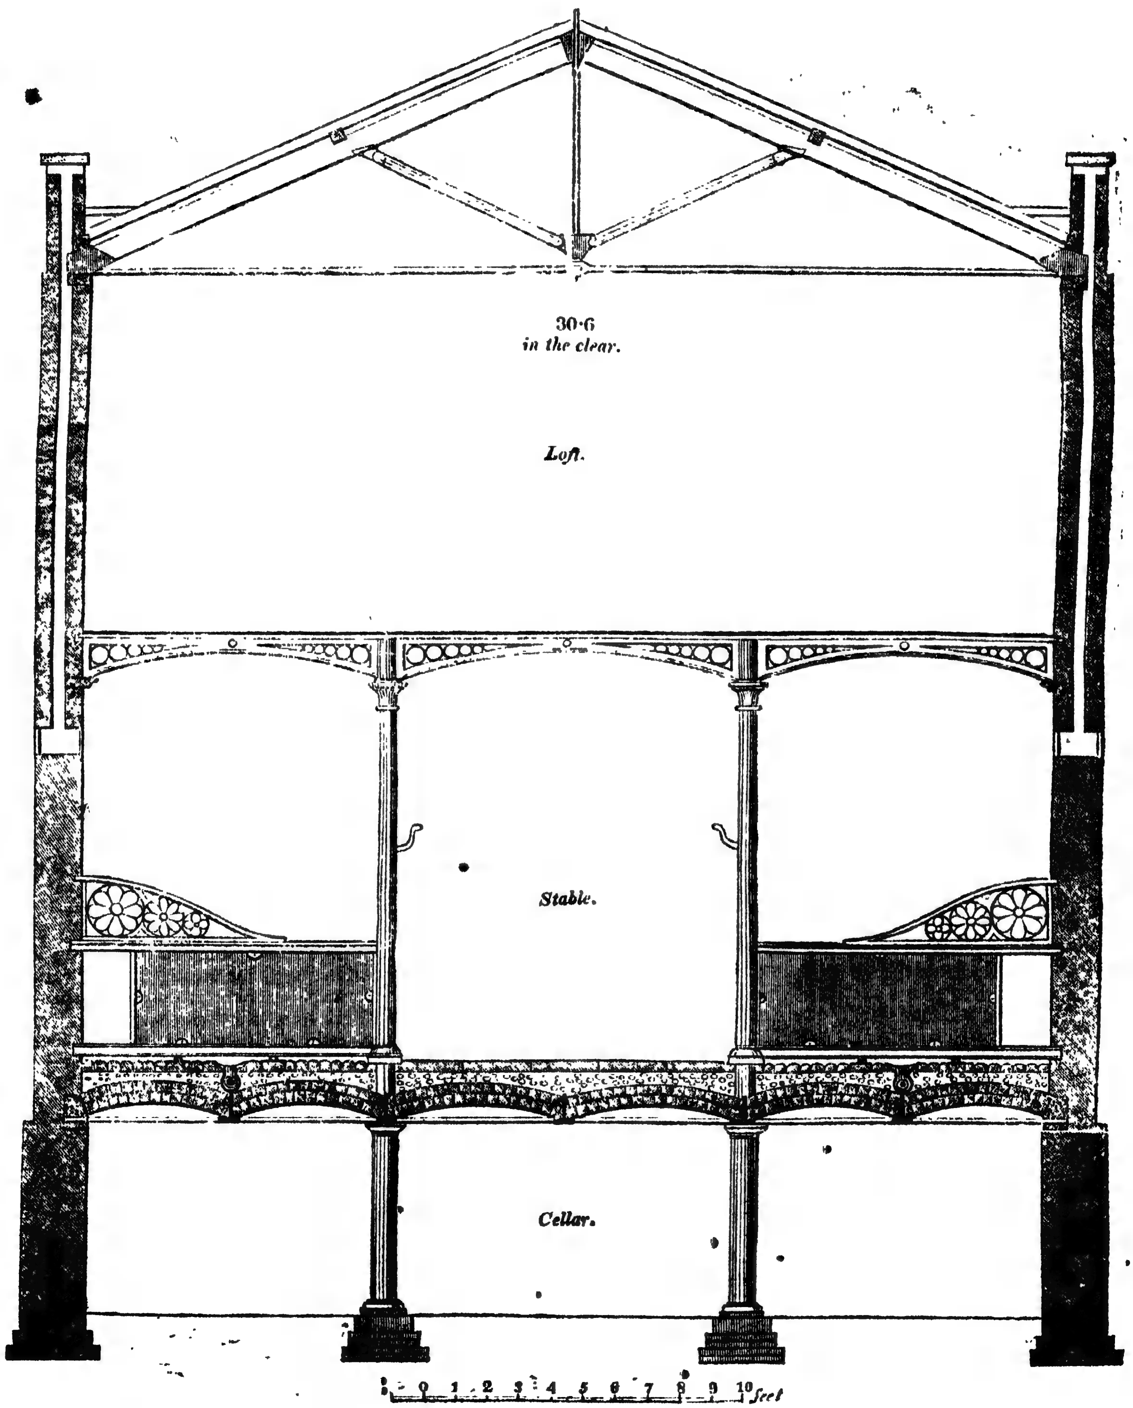
THE NEW STABLING

AT MESSRS. TRUMAN, HANBURY, BUXTON, AND CO'S BREWERY, BRICK LANE, SPITALFIELDS.

CONSTRUCTED AND ERECTED UNDER THE IMMEDIATE DIRECTION OF R. DAVISON, ASSOCIATE MEMBER OF THE INSTITUTION OF CIVIL ENGINEERS.

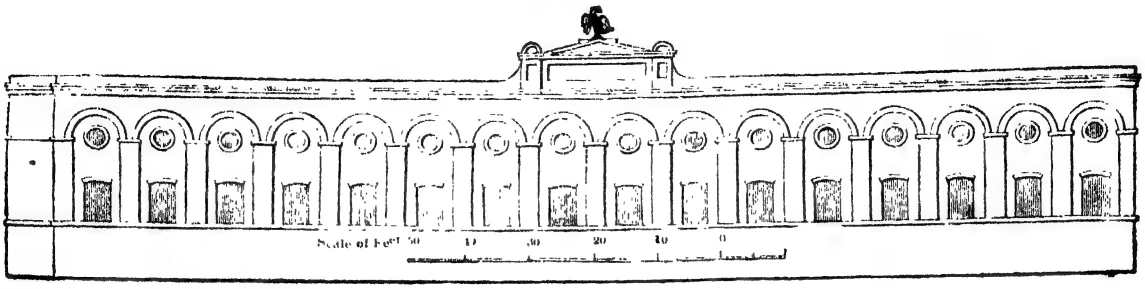
These stables are considered to be the most complete of any establishment in London, no expense being spared to render them both convenient and suitable for the purposes intended; considerable judgment and ingenuity has been displayed throughout the building, particularly in the construction. The architecture of the elevation is remarkably well designed for the purposes of the building; it is plain, well proportioned, and free from frivolity. The design presents a plain basement surmounted by pilasters, from which spring continuous archivolts; throughout the whole length is a bold cornice with a panelled attic over the centre, with a pediment and an eagle towering on the apex. The space between the pilaster or piers are occupied with windows; the upper ones are circular, with architraves, which gives the whole design a very neat finish.

SECTION OF ONE OF THE STABLES.

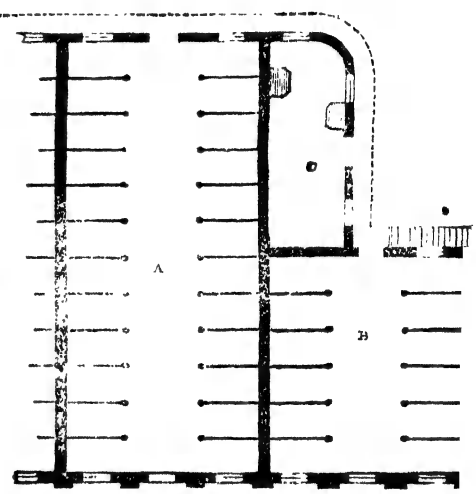


Scale of feet.

ELEVATION OF FRONT.



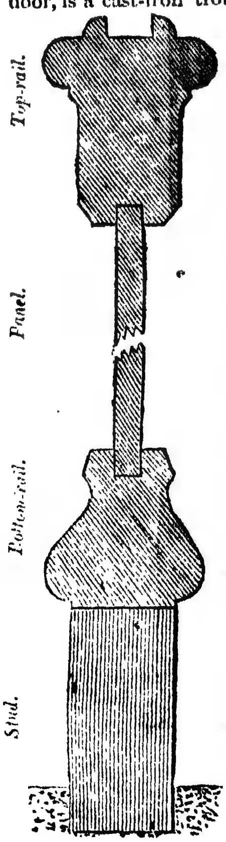
DESCRIPTION OF THE BUILDING.



The general arrangement comprises four stables, each 69ft. long and 30ft. wide; one of them is shown in the plan annexed, marked A. At one end is an additional stable (B), containing twelve stalls and a farrier's shop (C); at the other end is the infirmary, containing six boxes, making a total accommodation for 114 horses.

The general construction is shown in the section; each stable is fitted up with stalls 5 feet 9 inches wide from centre to ce e, and divided by iron partitions, as shown at large by the annexed drawing.

The frame is of cast-iron, with an ornamental head-piece, and the panel of wrought-iron a quarter of an inch thick, fitted in the groove cast in the frame, as shown in the annexed cut which is drawn one-fourth the full size; the heel-posts are of cast-iron, fluted, and have a very neat appearance; every other post is the whole height of the stabling, and carries the floor above: each post is furnished with two hooks to hang the harness on. At the head of the stall is a cast-iron manger, 3 feet 8 inches long, 14 inches wide on the top, and 12 inches deep, supported on a cast-iron bracket, which is secured through the wall as shown in the section. Above the manger the wall is lined with half-inch slate slabs as high as the top of the ornamental head-piece, and above is a cast-iron tablet, containing the horse's name; in the centre of each stall is a grating communicating with a cast-iron drain or pipe, as shown in the section, running the whole length of the stabling; through this pipe a stream of water is allowed to run for a few minutes every morning to thoroughly cleanse it. At the end of each stable, opposite the door, is a cast-iron trough, with pipes and cocks for supplying hot and cold water. The stables are ventilated both below and above by several air-bricks, as well as by eight flues in each stable, which ar carried up in the party walls, having moveable ventilators to regulate the egress of foul air; in addition to these, th windows (of which there are six in each stable) have the centre part to move with a lever, in the same way tha louvre boards used in breweries usually work, by which means a space equal to 40 square feet in each stable can b thrown open to the atmosphere, or closed as may be found necessary.



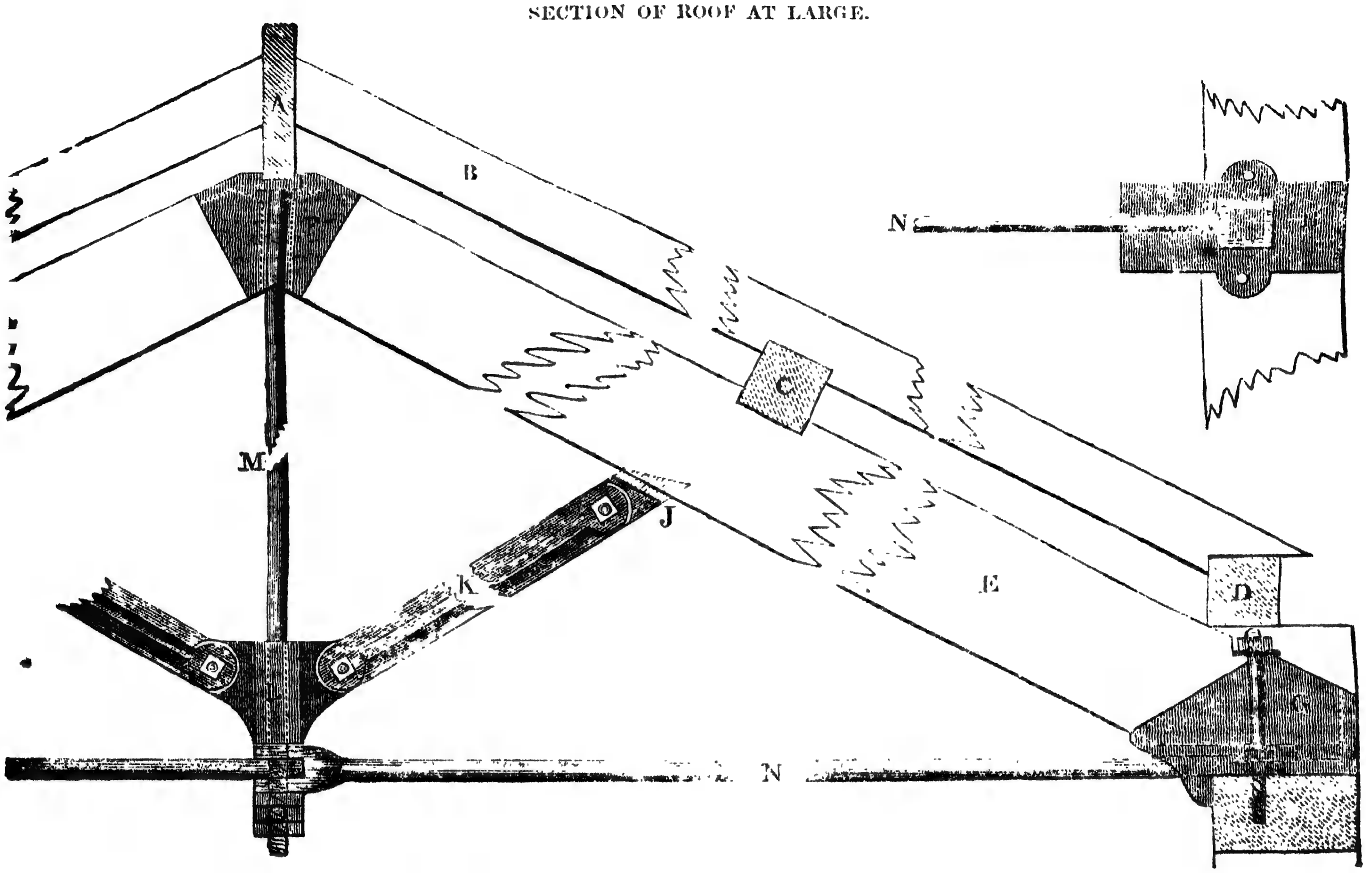
The middle part of each stable (that is to say, between the heel-posts) is paved with 5-inch Aberdeen granite, laid i regular courses, length-ways with stable, each course being 2 feet 2 inches wide, and having grooves or chases cut acros them 6 inches apart; when laid, the whole has the appearance of so ma. y parallel lines. Between the iron divisions paved with pebbles, averaging about 4 inches square at top.

The floor on which the paving is laid is constructed thus:—Upon iron columns, immediately below those which forn the intermediate heel-posts of stable-rest iron girders, with joists joggled into them, as will be seen by referring t drawing, skew-backs are formed on the flanges of the latter, and two rings of 4-inch brickwork, in cement, sprin from them; the spandrells are afterwards filled in with refuse bricks mixed up with grout, upon which is laid sufficier dry rubbish to bring the paving to the level required. The space below the entire range of stabling is occupied as al store-cellars, the casks being conveyed through an iron tunnel across the street, by an ingenious contrivance, which w intend to give a sketch of at some future opp rtunity. The floor of cellars is concrete, composed thus: dry lime, on part; Thames sand, one ditto; clay, burnt, 3 ditto; gravel, 5 ditto, mixed with boiling water.

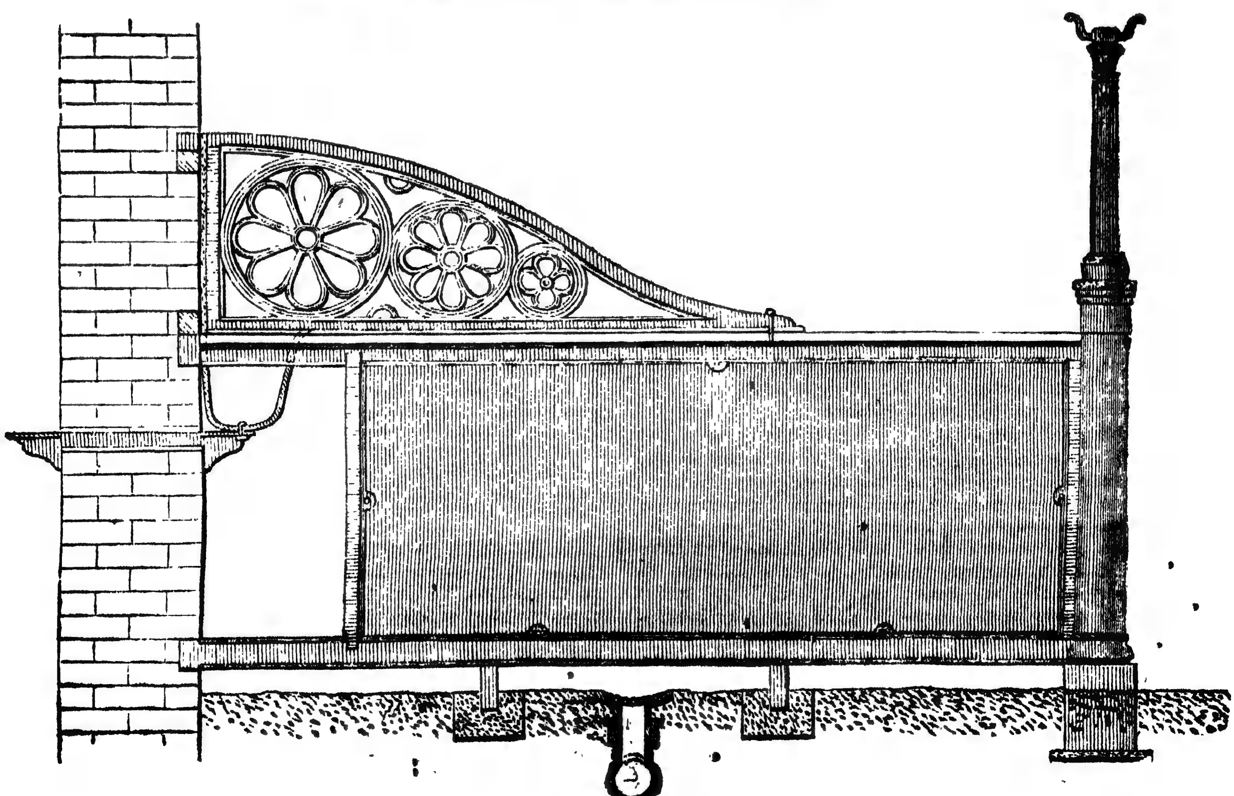
Over the stabling are the lofts. The floors are of cast-iron plates, half an inch thick and 33 inches square; th top is made rough by concentric grooves being cast on the face; these plates are laid on cast-iron joists, framed int longitudinal bearers or girders, resting on the top of the heel-posts, as shown in the section. The floor, both from th underside and over, has a very neat and light appearance, and renders each stable perfectly fire-proof. The roof over th lofts is deserving of notice; it is judiciously framed of cast-iron and timber, as shown in the section, and the parts mor at large in the annexed figures.

A ridge of fir, 10 × 1½ inches: B common rafter 4 × 3 inches, placed 13 inches apart: C purlin, 5 × 5 inches: D pol plate, resting on block, spiked on the foot of the principal: E principal rafter, 9 × 5 inches at bottom, and 8 × 5 inche at top, which abut against and let into the cast-iron king-head F; the foot of the principal is let into and abuts on a cast-iron shoe, G, and screwed by a screw-bolt, which passes through an eye made in the end of the tie-bar, and is thus secured and prevents the rafters spreading at the foot. This shoe is cast with cheeks, and a plate on the underside; it is fastened on to the wall plate, H, by two screw-bolts; the underside of the shoe is shown in the side figure, and the manner the iron tie is secured: J cast-iron abutment plate to the strut, upon which the principal rests: K cast-iron strut, with feathers on each side to strengthen it; each end is fixed in a circular joint by nut and screw-bolt: L cast-iron abutment, with a pipe or hole in the centre for the king-bolt to pass through: M king-bolt of wrought-iron, 1¼ incl diameter, with a large head, which rests on the top of the king-head; the bolt passes through the head and lower abutment joints and a shackle joint in the centre of the tie-bar; the lower part of the king-bolt is tapped with a screw and nut, which firmly screws up the whole of the roof: N is a round wrought-iron tie-bar, 1⅝ diameter, with a shackle joint in the centre, and square eyes at each end, which are secured to the wall-plates as before described.

SECTION OF ROOF AT LARGE.



ELEVATION OF PARTITION BETWEEN THE STALLS.



Scale half an inch to one foot.

WEIGHT OF IRON-WORK TO ROOF.

		lbs.
Cast-iron king-head F		45
Do.	Abutment joint L	23½
Do.	Shoe G, each 61*lbs.*, the two	122
Do.	Plate J, each 13*lbs.* the two	26
Do.	Strut K, each 103*lbs.*, the two	206
	Total weight of cast-iron	422½
Wrought iron King-bolt M		30
Do.	Tie bar N	160
Do.	Bolts, nuts, and screws	11
	Total weight of wrought iron	201

STABLE FITTING.

	lbs.	Cwt.	Qr.	lb.
Cast-iron top rail of partition	260			
Do. bottom rail	300			
Do. back rail	40			
Do. ornamental head piece	150			
Do. heel-post and standard	282			
Total weight of cast iron	1032	9	0	24
Wrought iron panel		2	1	5
Cast-iron manger	224			
Brackets to carry two mangers on each side of party wall, 39*lbs.* say half	19½			
	243½	2	0	19
Total weight of iron-work to each stall		13	2	28

The circular or bull's-eye lights to the lofts, as shown in the elevation are of cast-iron, including the architrave, and are 36 inches in diameter in clear of frame, and weigh 218*lbs.*; cost £1 each. The lower windows to stables are of cast-iron, 6 feet 9 inches by 4 feet 6 inches, and weigh about 2 cwt. each.

Along the whole length of the back front, on a level with the loft floor, and communicating with each loft, is a balcony or gallery; the bottom is of inch slate slabs, and projects before the wall 33 inches, supported on cast-iron cantilevers let into the wall 5 feet 6 inches apart.

At one end of the building is placed a four-horse condensing steam-engine, for the combined purposes of cutting chaff, raising fodder into the loft, and pumping water from a well in the cellar for the use of the stable and other purposes.

The total weight of iron (wrought and cast) used in the building, is about 300 tons, the cost of which did not exceed £10 per ton, including all labour, fitting, and fixing!

The entire cost of the whole range of building, including vaults, lofts, &c., amounted to nearly £10,000, and was built and finished within six months after the commencement.

The great advantage attending the construction of these stables are—less chance of disease among the horses—prevention of splinters of wood injuring the horses—more durable than any other material—first outlay very little more (if any) than fittings of oak—and security against fire.

We visited these stables when they were finished, and also within the last few days, and found all the iron fittings of the stabling, notwithstanding the rough usage they are subject to by the dray-horses, in as good state and condition as when they were first erected; they are an ornament to the Brewery, and are an example of good taste and judgment, clearly showing, however humble the intention of the building may be, there is room for the engineer or architect to devote his thoughts and talents.

Mr. Davison is justly entitled to the highest praise for the judicious arrangement, the ingenuity displayed in the construction, and the taste exhibited in the architectural character of the whole building.

LONDON AND BRIGHTON RAILWAY.

We make the following extracts from a report lately issued by Mr. Stephenson to the shareholders of "Stephenson's Brighton Railway, or the Western Line," which may be considered as a comment or reply to Captain Alderson's report to the House of Commons, on the several lines of Railway, between London and Brighton.—We have purposely abstained from making any remarks, as we wish, first, to see the promised report of the engineers of the "Direct Line," which we understand will be ready in the course of a few days; we hope it will be issued in time for us to notice it in our next number.

"Captain Alderson commences his report by stating, that having examined minutely the various plans, and carefully the evidence, and inspected the country generally, he has no hesitation in asserting, that, in an engineering point of view, the Western Line, that is, the line proposed by me, is preferable to any other.

"Having made this declaration, he observes, that as this is only one point of consideration in a main line of railway, he will proceed to consider the respective merits severally of all the lines, in reference to the second resolution of the House of Commons.

"It must be concluded from these remarks, that, in reference to the first or leading instruction of the House of Commons, touching that line of railway to Brighton which is preferable in an engineering point of view, the military engineer decides in my favour—and it remains with me to enquire on what ground he has subsequently been led to give a preference to another line, by reference to the second instruction of the House of Commons, which directed his attention to the other sea-ports on the south coast.

"Captain Alderson opens this subject by observing, 'that the towns in the intermediate district between London and Brighton, and those on the coast, are of minor importance compared with Brighton;' as far as relates to the minor importance of Shoreham and Newhaven, as compared with Brighton, I agree entirely with Captain Alderson; but in regard to those places which have not entered into his consideration, and which, in obedience to the second instruction of the House of Commons, should, I believe, have been prominent objects of comparison, I entertain a widely different opinion; Worthing, for instance, is a place of considerable importance. The towns of Arundel, Little Hampton, Bognor, Chichester, and Portsmouth, all ports on the southern coast, are surely worthy of some attention. Portsmouth especially, being a maritime station, in every point of view must vie in importance with, if it do not outweigh in national consideration, the leading town of Brighton itself; and though the better accommodation of these places might have formed some excuse for the abandonment of the best engineering line, it seems to me that there is no such excuse for it, upon the ground of better accommodating places, which he considers to be of such minor importance. The fact, however, is, that the Western Line will better accommodate all these important places, will better accommodate Shoreham; and will equally well accommodate Lewes and Newhaven.

"As to the assertion, that there are no intermediate towns of consequence to be accommodated by the several lines, I am again obliged to differ in opinion from Captain Alderson; Epsom, with its celebrated races—Dorking, with the beauty of its adjacent scenery—Horsham, with its considerable corn market, are all places worthy of attention. Epsom alone, in one week, attracts from 300,000 to 400,000 visitors, and to these the Western Line alone offers accommodation; and it is not to be lost sight of, that it is of advantage for a railway to lead through an interesting and picturesque country which is likely to fix the attention of new residents, and thus to create an increasing and profitable transit of passengers. This seems to have escaped the notice of the military engineer, although it is a point greatly in favour of the Western Line, that it does pass through a conspicuously beautiful district; whilst the Direct Line from Croydon to Brighton, does not touch a single town throughout its whole course, and the country through which it passes is generally sterile, uninviting, and little likely to be chosen as the site of new residences. The assertion of Captain Alderson, 'that there are no intermediate towns to be accommodated by the respective lines,' applies, indeed, in full force, to the Direct Line; but not to all the respective lines. Had he considered more at large the interests of the proprietors, whose capital was to form the line, these various considerations must have forced themselves upon his attention—they have always weighed with me; they did so when I came to a conclusion, that unless you could carry the Western Line, it would be scarcely prudent to attempt any other, and of this opinion I still remain." * * *

"According to Captain Alderson, the Western Line is fittest to be adopted, from the superior facilities of its execution, but the termini of the Direct Line are superior, and therefore, that it ought to be adopted.

"The report then proceeds to comment upon the London termini of the respective lines, and the engineer, for the purpose of comparing them, adopts the northern end of Blackfriars Bridge as the centre of population. I think Captain Alderson would find, upon more mature reflection, that his adopted centre would be rather eccentric. However, let us for a moment assume this centre, and see how he deals with it. He informs us that the Greenwich Railway terminus lies within a circle of a mile radius; this information is of little use to those who wish to know how they are to reach these places by the ordinary thoroughfares. To such it may be acceptable to know that the distance from the Greenwich Railway terminus to the centre, is 1½ mile through crowded streets, where an average speed of 4 miles an hour can seldom be exceeded; whereas the distance from the same point, to the Vauxhall terminus, is 2½ miles; which, as the intermediate thoroughfares are wide, and out of the great throng of business, might be easily traversed at a speed of 8 miles an hour, and therefore this latter terminus could be reached generally in considerably less time than the former.

"Captain Alderson, nevertheless, appears to think, that plans and estimates having been formed for the lateral enlargement of the Greenwich Railway, very little remains to be done to fit it for the prompt reception of the traffic of the main southern trunk-line of railway; and he proceeds to report accordingly, omitting all mention of the fact, that the Greenwich Railway Company possesses no area for an enlarged depot, and that the small space in the possession of the Croydon Railway Company is not at all adequate in area, nor adapted in position, for the purpose, being on the opposite side of the Greenwich Railway to that which the Brighton traffic must use.

"Now this is, in my opinion, of the last importance, for it is but of little avail to attain a central terminus, unless its possession be also adapted to the formation of a depot; all who are acquainted with the nature of the property in the vicinity of the Greenwich Railway, must be aware of the enormous outlay which will be required to purchase every acre of land requisite for this purpose. If this, I may say, almost vital question in the consideration of a main line of railway had occurred to Captain Alderson, my belief is, that he would have looked any where rather than to the Green-

wich Railway for a terminus to the main southern trunk-line of Railway; if the course of Captain Alderson's investigation had led him to enquire into the facilities of the Southampton Railway, he would have learned the fact, that no additional widening would be required for the five and a half miles of this Railway, which the Brighton traffic was intended to traverse, had the Western Line been adopted, as the trains would necessarily pass on this line, at longer intervals than on the Greenwich Railway; and further, that the Southampton Railway Company possesses an area of six or seven acres for the formation of depots, with access to the river, and that this space, if found insufficient for the Brighton traffic, could be extended at a reasonable cost, the neighbourhood being comparatively open and free from buildings. He might also have learned that plans and estimates were already framed for extending, if necessary, the Southampton Railway to the neighbourhood of Waterloo Bridge.

"Had Captain Alderson known these facts, or knowing them, had he considered them, he would perhaps have placed the question of the London termini in the following point of view:—The Greenwich Railway requires widening; the Southampton elongating; the Greenwich Railway cannot receive further traffic, without an immense outlay to obtain space for a suitable depot; the Southampton has already an area of six or seven acres, which will probably be sufficient, but if not, it can be enlarged at a trifling expense. After widening the Greenwich Railway, and expending a large sum for the purpose of obtaining a depot, it would be inconveniently situated in a crowded neighbourhood; whereas, by elongating the Southampton Railway, a station would be obtained at Waterloo Bridge, probably the best position in all London; such extension affording besides the additional advantage of a third depot at, or near to, Westminster Bridge." * *

"We come next to his observations on the Brighton termini of the several lines laid before him. He begins by informing us, that the terminus of the Western Line is inconvenient for passengers from London, and for goods coming from Shoreham, as not being central. He then goes on to say, that the Direct Line has two depots, one for passengers at Church-street, 35 feet above the ground, and communicating with Church-street by an inclined plane, and another for goods at Trafalgar-street; and he observes, that the Church-street depot is the most central. Here there is an inaccuracy, for if Captain Alderson had taken his information from the printed evidence, he would have ascertained that the inclined plane from the Church-street depôt communicates with North-street, and not with Church-street; and the report omits to inform us that this inclined plane is 200 yards long, rising 1 in 5¼, being, in fact, steeper than Holborn hill. Now it must be observed that the Church-street depot is intended only for passengers; the depot for the goods is not here, but in Trafalgar-square, 500 yards farther back, or altogether 700 yards from the foot of the incline in North-street; and the terminus of the Western Line is at a distance of 800 yards from the same place, the approach to which, for the purposes of ordinary travelling, *is on a level.*

In the second place, the distance by railway from Shoreham, to these respective depots is 6¼ miles, to that of the Direct Line; and 5¼ miles to that of the Western Line—the gradients being 20 feet per mile on the Direct Line, and 16 feet on the Western Line; consequently, by the Western Line, besides a better gradient, there is a saving of 1 mile in the distance from Shoreham. * *

"Captain Alderson states it as his opinion, that the slopes in the cuttings in chalk of one-sixth to one, are dangerous; and that slopes of one to one must be substituted for them; this alteration alone increases the excavation of the Direct Line by 4,500,000 cubic yards (a quantity nearly equal to the whole of the excavations on the Grand Junction Railway, *though* 77 miles in length); which, with the consequent extension of the bridges, and greater quantity of land to be purchased, would add at least 250,000*l.* to the estimate; an excess to be counterbalanced only in a small degree, and that by no other means, than by the very objectionable plan of lengthening the tunnels. * * *

"From the result of my inquiries, I have not a doubt that water exists in all the great works of the Direct Line, viz., at the Merstham, Clayton, and Balcombe summits, and at certain seasons of the year in great quantities. The presence of superabundant water has the effect of preventing, at intervals, the prosecution of the works; for where the natural drainage is insufficient to let it flow freely off, artificial means must be resorted to; the construction and working of which necessarily add enormously to the expense of the works. Moreover, as these excavations are mostly confined in narrow valleys, the difficulties attending any artificial means of freeing the works from water would be, consequently, much aggravated. The following table, containing the particulars of the three great works on the Direct Line, the greatest cutting on the Western Line, and the heaviest excavation on the London and Birmingham Railway, which is a chalk cutting at the Tring summit, will give some idea of the comparative nature of these works.

Name of Railway.	Name of Excavation.	Length.	Greatest Depth.	Contents.	Tunnelling.
		miles.	feet.	cubic yards.	yards.
Direct Line......	Clayton......	2¼	76	1,450,000	1700
	Balcombe	1¼	70	500,000	880
	Merstham	2¾	90	2,750,000	1320
Western Line......	Capel........	$1\frac{1}{10}$	57	700,000	none
London and Birmingham......	Tring........	2½	57	1,250,000	none

"We thus perceive, that the Clayton cutting exceeds the Tring both in contents and depths, with the addition of a tunnel of 1700 yards long; next, that the Balcombe cutting exceeds the Tring in depth, but is less in contents, there being however a tunnel of half a mile in length on a curve of a mile radius, which is a fact rather strangely omitted in the report; lastly, we find that the Merstham exceeds the Tring cutting both in depth and length, being more than double its contents, with the further addition of a tunnel of three-quarters of a mile in length, and is four times the extent of the largest cutting in the Western Line, besides the above tunnel.

"The three cuttings, the Clayton, Balcombe, and Merstham, are all of them situated at the bottom of narrow valleys, where water will beyond a doubt be found, there is consequently nothing to justify the opinion, that they are to be done in less time, and at a less cost, than the Tring cutting; which is, as I before said, in an open country, with lower levels to assist its drainage. To examine this further, the united length of these cuttings does not exceed 8¼ miles, yet in this small space there are 4,700,000 cubic yards of excavation, and 2¼ miles of tunnelling; comprising an amount of excavation exceeding one-third of the whole on the London and Birmingham Railway, and nearly equal to the total quantity executed on the Grand Junction Railway, between Birmingham and Liverpool; and lastly, being actually equal to three-quarters of the total estimated excavations on the Western Line, whilst the amount of tunnelling is one-half of the whole on the London and Birmingham Line, and nearly four times the amount of the Western Line.

"Having mentioned the stupendous projected works on the Direct Line, and compared them with one of the heaviest excavations executed in this country, I leave it to others to determine whether the Report conveys any idea of their real importance, magnitude, and difficulty of execution, and to judge of the probability of their ever being completed within a period, and at a cost consistent either with the evidence given in their favour, or with the selection which Captain Alderson has made. I also leave others to decide whether the opinion of Captain Alderson, of the advantages of approaching Brighton prior to Shoreham, justifies works of this unparalleled extent.

"Captain Alderson's brief description of the embankments on this line, conveys impressions which, to me, appear little consistent with their real character.

"It is stated, 'that the embankments, on the whole, are less than the excavations;' and, 'that there are many short deep valleys to be crossed by embankments.' Let us examine these statements.

"From the 9¼ to the 21st mile of the Parliamentary Section, that is, in a length of 11½ miles, there are 9½ miles of embankments. Surely the description of short valleys does not apply to this part of the line, although the epithet of deep is appropriate enough, for the embankments are in places 50 feet high. Between the Balcombe and Clayton summits, a distance of 12 miles, there are several very heavy embankments, varying from 1 to 1½ miles in length, and from 60 to 80 feet in depth. That these valleys are deep, is certainly quite true; but what can justify the designation of *short*, as applied to them! By Mr. Rastrick's estimate, the united amount of these embankments is 2,439,000 cubic yards; a quantity, in the space of 12 miles, never yet attempted on any railway, or even seriously proposed, except in the present instance.

"Captain Alderson is quite correct in saying 'the embankments are badly disposed, and would consequently require much side cutting;' and if he had consulted Mr. Rastrick's evidence, he would have found that none, or a very small quantity, at most, is provided for; and he would have found in this another proof of the insufficiency of the estimate.

"On the other hand, on the Western Line, the *gross amount of embankments* is more equally distributed over a longer line, and thus has many more facilities for execution: the total length of embankments, exceeding 40 feet in height, is 3,100 yards on the Direct Line; but on the Western Line it does not amount to 500 yards. These important facts are, however, all unnoticed in the Report." * * *

"I have now alluded to the several points in Captain Alderson's Report. I do not complain of any opinions which Captain Alderson has formed upon sufficient and accurate data, though they may be at variance with an extensive practice, but I will briefly recapitulate the principal inaccuracies and omissions by which he has supported his selection:—

"*First*.—By a perversion of the instruction of the House of Commons he sets aside the best engineering plan, and sacrifices the interests of Worthing, Portsmouth, and other places on the southern coast, for the mere purpose of preserving the monopoly of the town of Brighton, and with that view objects to Shoreham, the present port of Brighton, being accommodated on a main-line of railway to Brighton; substituting, however, an expensive branch to Shoreham, with the ruinous branches to Lewes and Newhaven, none of which are available for any other object.

"*Secondly*.—He supports his decision of the superiority of the termini of the Direct Line by an incorrect estimate of distance from the centres to the respective depots, and after recommending works of great cost on the Greenwich Railway to meet its admitted defects, he omits to add this additional cost to the estimate of the Direct Line, neglecting to state the important advantages which would accrue to the Western Line from a much smaller outlay; nor has he alluded to the nature of the property in the vicinity of London Bridge, offering as it does an all but insurmountable barrier to the obtaining any depôt on that spot.

"*Thirdly*.—To support his selection of the Direct Line, he has adapted tables which contain principles in direct variance to those adopted as the basis of a report to the Legislature in April last, and to test the facility of execu-

tion of the respective lines, has quoted estimates which he admits to be inadequate; and,

" *Lastly*—He has altogether omitted to notice the inclined plane of $2\frac{3}{10}$ miles on the Croydon Line, the objections to which are established alike by the concurrent opinions of all engineers, and by the result of all experience.

" I have very reluctantly revived this subject; but it has appeared to me to have been forced upon me by the circumstances of the case; and when it is considered that all these errors, omissions, and fallacies in Captain Alderson's Report, are invariably in favour of the Direct Line, and against the Western Line, I trust that it will be considered that I am doing nothing more than is necessary in vindication of my professional character."

AMERICA.

We have been favoured by Mr. Weale with the following extract of a letter he has just received from Ithal Town, Esq., Architect:—

New York, Nov. 3, 1837.

MY DEAR SIR,—After waiting some months, in hopes I might have something better to write to you, in regard to the business and situation of our country, I regret to state, that very little improvement has yet taken place, and our wisest men are doubtful whether a much better state of things can occur sooner than next spring or summer. We have had a fine *crop year*, and a season free from sickness, of a contagious kind, except New Orleans, and some smaller places near it. I have finished my house, and have been living in it since June: the room for my library is a very good one, 45 feet long and 23 feet wide, and of the same height as width, with two sky-lights. My books are in it, but not yet in the book-cases intended for them. My study, a room 17 by 16 feet, adjacent to the library, is fitted up very comfortably with all necessary cases, and for the accommodation of many of the best books, engravings, paintings, and other works of art. My great western bridge is still suspended in its progress, and cannot again progress until better times. It gives me great uneasiness to have such a work suspended, and the loss of time and money will be very severe upon all concerned; still it is fortunate that we had not proceeded farther in the expenditure than we *had* when it was stopped, viz., about 230,000 dollars. * * I shall soon have a wood-engraving of my house made, and will send you a view of it. I will also send you some of the publications of our country, *such* as will give you information suited to your wants for aiding in some of your numerous publications. Our new Custom-house is nearly up to the top of the columns, and will be finished in two years probably. The new Merchants' Exchange is in rapid progress, on a much enlarged plan, and will be a good fire-proof building, suited to the uses. The Girard College, at Philadelphia, by Thos. U. Walters, Esq., architect, is a fine building, and will be finished in about two years. The State Capitol at Raleigh, North Carolina, all of granite, is by far the finest building of the kind in our whole country—it will cost over half a million of dollars, and is nearly finished. This building was executed under my charge of the architectural department, and is, as I think, as good as any thing I have ever designed, *which has been executed* in as good material, and with equal workmanship. The Capitol of Indiana is a better design, but is executed in bricks, covered with cement, in imitation of *free-stone*.—Respectfully, dear Sir, your obedient servant,

ITHAL TOWN.

P.S.—I have (since the above was written) just had the honour of a visit at my house in New Haven, from Professor Dobeny, D.D., Professor of Chymistry and Botany at Oxford. I am indebted to Professor Silliman, my nearest neighbour, for this honour; he came with Professor S., and seemed pleased to perceive that we are a little *bitten* with the same disease, that so many of his countrymen are, viz., the book *mania*.

USE OF THE PATENT DIVING DRESSES IN EXAMINING AND REPAIRING SHIPS.

The following extracts describes the service performed by *Mr. Bethell's Patent Diving Dresses* to H.M. ship "The Thunder," at the Bahama Islands, in the West Indies:—

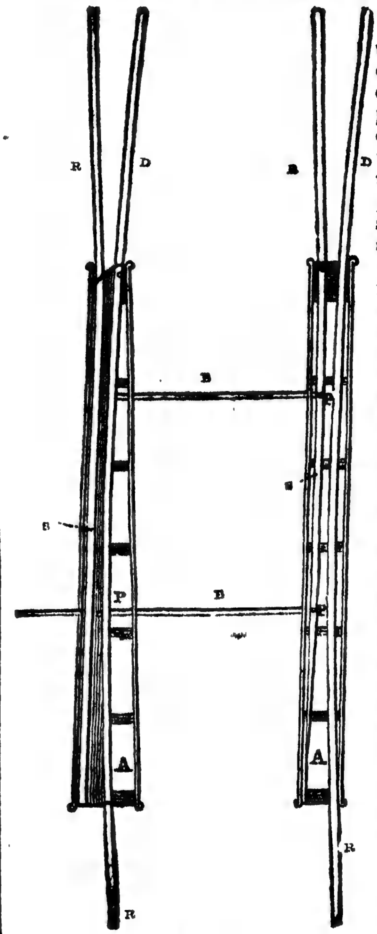
" *The Thunder Surveying Vessel.*—The extent of the injury was exactly ascertained by means of a diving apparatus, kindly lent by a private company at Nassau, who had imported it for the purpose of getting goods out of the holds of vessels sunk in deep water.

" Mr. Wilson, the master carpenter (with a zeal and perseverance that do him infinite credit), after several trials, became so skilful in the use of it, that he was enabled to remain down upwards of half an hour, in three fathoms water, with perfect ease, and nailed two pieces of copper over her worst holes, which gauged $2\frac{1}{2}$ inches deep, thus enabling the ship to make her voyage across the Atlantic, without the smallest increase of leakage. Such advantages should be secured to all our foreign dockyards, for by their being supplied with one of these useful machines, the exact amount of damage to any vessel may always be ascertained, and repaired without loss of time. The Thunder came into harbour on Monday, to be paid off."—*Hampshire Telegraph.*

Improved Diving Dress.—" A trial of Mr. Bethell's diving apparatus was made last week in one of the docks of Portsmouth Dockyard, in the presence of Admiral Sir P. Durham, Rear Admiral Sir F. Maitland, the Master Shipwright, Captains the Hon. R. Dundas, Searle, Maitland, and many other Officers of the Navy and Dockyard, which gave perfect satisfaction. The descent was made by the master carpenter of H.M.S. 'Wellesley,' preparatory to the machine being taken on board that ship, to be conveyed to the East Indies, for the purpose of examining and inspecting vessels which may have touched the ground, and thus, without expense, ascertain the extent of damage sustained, and the repair required. We hope such a useful article will continue to be supplied to all flag-ships, at least, to enable the Commander-in-Chief to hold a survey on vessels, before either the expensive operation of heaving down is resorted to, or the vessels are sent home."—*Naval and Military Gazette.*

With these dresses, a ship can be examined and repaired whilst at anchor, in any depth of water, the diver being seated on a small stage, which is moved about under her bottom.

CURTIS'S RAILWAY SWITCHES.

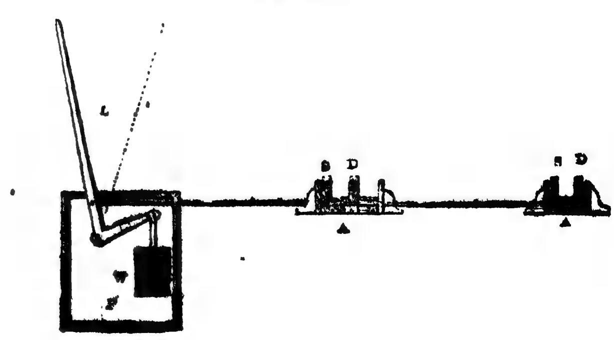


THESE switches, as contradistinguished from those of the ordinary construction, are formed double, one straight bar corresponding with the line, and the other curved, corresponding with the diagonal; by this arrangement the angle is last; thus, a train passes through them with the same smoothness as over the line, and those shocks which are so injurious to the engine and carriages are wholly avoided; besides which, if the curves are formed with the same radii as those upon the line, an engine and train may travel through with perfect safety at full speed. Fig. 1 is a plan of the switches, but in this instance, one of the improved switches are only employed; viz., upon the outside of the curve, which is the guiding rail in all cases, the inner or passive rail being provided with a single-pointed switch: this method is better in the general way than a double switch on both sides, because it is lighter and cheaper, and shuts against a solid rail, thus giving the switch greater solidity than by the other method, and it will, moreover, work more equally; the centre of the double switch is placed in the diagonal rail, thus the engine has always a tendency to keep the rail in its place as it goes over it, whether backwards or forwards.

Fig. 1 is the plan and Fig. 2 the section: the end line R R are the rails of the line, D the diagonals, S the switch-bars corresponding with the straight line, A the bed-frame for the switches to work in, B the connecting bars, one of which is connected with the lever L, P the studs or pivots by which the bars are united to the switches; W is the counterbalance weight, which always keeps the switches right for the line, an important arrangement, which ought never to be lost sight of; F the box for the weight and lever to work in; when the switches are right for the line, the lever occupies the place shown by the dotted line.

Fig. 3 is a plan of the switches so arranged, that an engine can never run off the line under any conditions of the switches being wrongly placed. (We are obliged to postpone the description of this last arrangement until our next Number, in consequence of the wood-cut not being finished.—*Editor.*)

SECTION.



SCIENTIFIC INSTITUTIONS.

ARCHITECTURAL SOCIETY, 35, LINCOLN'S-INN-FIELDS.

Opening Meeting, Tuesday Evening, Nov. 7th, 1837, W. B. Clarke, Esq. President, in the Chair, for the Session 1837 and 1838.

The Meeting was very numerously attended by the profession. We observed among them—Sir Richard Westmacott, R.A., Philip Hardwick, Charles Barry, T. Hopper, C. Fowler, T. Chawner, J. Newman, J. Kay, J. Britton, H. R. Abraham, and F. Wishaw, Esquires.

Numerous drawings were exhibited by Messrs. G. Moore, H. Dewsbury, G. Hawkins, Wm. Grellier, R. E. Philips, G. Alexander, &c., &c., members.

On the table were laid various interesting Works of Art and Portfolios of Drawings by Messrs. Moore, Finden, and Nash.

The Curator announced various donations to the Library and Museum, by J. Britton, Esq., T. L. Walker, H. Dewsbury, R. E. Philips, &c., members.

Mr. Owen Jones (member) contributed some casts taken from the Alhambra, which were elucidated by a view in outline of the interior, beautifully etched by Mr. T. T. Bury, member.

Mr. Cowell also exhibited a very interesting and useful model of his patent Sash Suspender. It is for the prevention of accidents in cleaning windows, and is so simple, that a servant can detach the Sash from the lines and rehang it in one minute. The price is a mere trifle; the fastening prevents the rattling of the Sashes. Also his Patent Sash Fastenings, which are extremely simple, and ought to be introduced by all architects in any new or old buildings, when they have an opportunity of doing so.

W. B. Clarke, Esq., the President, delivered the following address:—

"Gentlemen,—Having been elected for the eighth time your President, the duty of opening our present Session with a short address devolves upon me. I could have wished that the honour of the Presidentship of the Architectural Society had been bestowed upon some other individual better able, by his learning, talent, and genius, to fill this high and important office, rather than so humble and unknown a person as myself. I still hope, however, for the valuable interests of this Society, that the day may not be far distant when some one of the leading Architects of the present period will consider it an honour to direct and improve the architectural knowledge and taste of so large a portion of his fellow-labourers in the same honourable avocation.

"The Architectural Society has laboured for now seven years in those arduous and laudable endeavours, with which it commenced its career, to advance the science by a liberal intercourse amongst its members, and the natural interchange of ideas which must arise from such intercourse. We must all feel, who have participated in the benefits held out to architects by this Society, that our ideas have materially enlarged, that our liberality has been strengthened, and that we have already gathered much valuable information, which unassociated we should not have acquired. The want of this association was deeply felt by all of us previous to the foundation of this Society, and with these feelings we dearly cherish an institution which offers us advantages not to be obtained in any other similar Society, either in this Metropolis, or even in Great Britain. If, therefore, we esteem and value these benefits, how much more estimable must they be to the unpractised student. I consider his coming in contact with a numerous body of architects already in practice, many of whom have travelled, and all, with various and valuable architectural lore, to be an excellent and invaluable advantage conferred by the Architectural Society on him. The liberality of the Members of this Society, in affording every species of information with which they are acquainted, when required of them by the student of the Architectural Societies is such as naturally flows from the worthiest motives; the intention and desire to promote the advancement of architectural knowledge which, when thoroughly understood, and combined with correct taste, honours the country that gives birth to, and matures it. Greece, from her pre-eminence in the Fine Arts, and especially in Architecture, was honoured and respected long after her political power had become insignificant in the scale of nations. Italy, powerless as a divided nation, is still considered the nursery of the Fine Arts, and architects from all quarters of the Globe learn the best principles of architectural taste from the great architects of the *cinque cento* period; nor do we find less learning and combination of form in the earlier architecture of this Island; appropriately, though perhaps erroneously, called English, from the very high state of perfection to which it was brought. To the associated learning of the cloister we are indebted for the superb piles of Gothic building, so finely preserved in this country, and to such learned patrons of art and architecture as William of Wyckham and his predecessors do we chiefly owe the theory and practice in England of this beautiful style of architecture. And here I may reflect, how mainly instrumental in all times, but especially in our own island, have learned men been in fostering and giving a right direction to the Fine Arts. For the introduction and the inculcation of the correct principles of Roman architecture in Britain, we stand, I believe, more indebted than we are aware to the learned men of the fifteenth and sixteenth centuries, who, in the reign of Elizabeth, and still more, in James I., brought in with them from their travels a love for the modern Italian style of architecture, based on the principles and taste practised in the most palmy period of the Roman Empire.

"Considering that Architecture has been admired by, and is indebted to men of science, learning, and research, in all ages, it is, and should always be the endeavour of the Architectural Society, to cultivate the acquaintance of men of science and of letters, assured that, by such a course, they will acquire a more varied store of useful information, which may often be made to bear upon their peculiar art.

"But, however valuable to mankind may be the study of the arts and sciences, and however admirable and delectable may also be the study of Architecture, and useful the practice of it, still we must bear in mind, that in a period of profound peace only can they, and architecture especially, from its costly nature, flourish.

"During the period in which Europe has been afflicted with long and calamitous wars, the arts have been neglected, and have become degenerated and debased. But when peace has been restored, they have gradually risen from their inferiority and debasement, and with the increase of peaceful years nations attest, by their noble works of art, and the monuments of architecture raised throughout their lands, the blessings of peace, and make them, by comparison, detest the misery, waste, and destruction consequent on war and its train of horrors.

"Long has this country enjoyed the advantages of quiet and repose, and the beneficial results are being reaped hourly by its industrious and wise population.

"Animated by so powerful an example, and stored with the experience of history, may we not confidently hope that our youthful, pure, and virtuous-minded Sovereign will, through a long, a happy, and a prosperous reign, cultivate those blessings of peace, on which not merely the Fine Arts and Architecture depend, but the more important welfare and happiness of every class of her subjects.

"If then we shall be blessed with continued peace, abundant time and opportunities will be afforded to the student to acquire, and to the architect to practise, his difficult and arduous profession—a profession in which something new, something valuable, through the longest life, is always to be gained; and the aphorism of *Ars longa, vita brevis*, is one which architects should bear in mind."

The following subjects were announced for the Students' Prizes for the Session 1837 and 1838.

No. 1. Design.—A Public Building for the Exhibition of Painting and Sculpture—comprising

Three Picture Galleries—Sculpture Hall—Entrance Hall, with Check and Money-takers Loggias, and Apartments for the Housekeeper.

A Plan of each Story—One Elevation—Two Sections, and a Perspective View, tinted in Seppia.—To be drawn to a scale of one-eighth of an inch to a foot.

No. 2. Measured Drawing.—Sir Wm. Chambers' Gateway on each side of the Quadrangle of Somerset House, including the two Foot-Portals leading to King's College and Somerset Place.

Accurately measured and figured Drawings, consisting of Plans, Elevations, and Sections, drawn to a scale of half an inch to a foot. One Elevation to be in outline, and one Elevation to be tinted and shaded in Seppia;—also, accurately figured, detail Drawings of the various parts.

No. 3. Essay.—The History of the Arch, giving the date and locality of its Origin:—trace its immediate effect on Architecture, its first introduction into the Ecclesiastical Architecture of Europe, and its various gradations through that style down to the Tudor Arch of our history.

State the Authorities consulted and referred to.

SOCIETY OF ARTS.

Nov. 2, 1837.—The weekly meetings were resumed this evening, W. Pole, Esq. one of the vice-presidents, took the chair. The secretary read the proceedings of the last meeting; after which he read several reports from various committees, particularly of *accounts*. He likewise exhibited the balance-sheet, &c. Many valuable communications and presents, which had been received during the recess, were then announced.

A communication of a donation of 500*l.* was also made to the Society, to be applied in providing annually two handsome silver medals, to be given for drawings, and a model of a design in practical carpentering, as applicable to civil architecture, particularly roofing, centering, &c.; also for drawings of a model of a design in practical carpentering, as applicable to naval and military architecture. Several members were elected, and others proposed.

The following are the subjects chosen for the evening illustrations:—

Nov. 14. } Dec. 12. } On Calico Printing. By the Secretary.

1838. Jan. 9.—On Pigments. By J. Hemming, Esq.

Feb. 13.—On the Application of Machinery to Engraving in Relief. By W. Brockedon, Esq.

Mar. 13.—On Respiration. By M. Truman, M.D.

April 10.—On the Manufactures and Arts of Ancient Egypt. By J. Williams, Esq.

May 8.—On Plain Weaving. By Ed. Cowper, Esq.

June 12.—On Jacquard and other Figured Weaving. By Ed. Cowper, Esq.

Nov. 14.—Alderman Winchester, V.P., in the chair. The secretary delivered a lecture on calico-printing. Mr. Aikin gave an historical detail of the art, interspersing it with many interesting anecdotes, and occasionally adverting to the more recent improvements. He exhibited several ingenious experiments, setting forth the effects of the colouring ingredients, and the progress of applying the mordants. He explained the different stages, from the plain cotton to the most perfect print.

MEETING OF SCIENTIFIC SOCIETIES.

Institute of British Architects, Monday Evening, at 8 o'Clock, Dec. 4 and 18.
Architectural Society - - Tuesday Evening at 8 „ Dec. 5 and 19.
Society of Arts - - every Wednesday Evening at 8 o'Clock.

PARLIAMENTARY PROCEEDINGS.

Conveyance of the Mail by Railways.—Tuesday, Nov. 21.

Mr. Wallace rose to move for the appointment of a Select Committee to inquire into the causes of the irregularities and delays which have taken place in the transmission of the mails by the Railway from Birmingham to Liverpool. It was perfectly well known what great regularity existed under the old mail-coach system in the transmission of the mails, but some irregularities had crept into the new system, the causes of which he was anxious to have investigated by a Committee of the House. Instead of arguing the question, he would state a few facts. The first Railway which had been used on a large scale for the transmission of the mails was that between Birmingham and Liverpool. At first the mails arrived very nearly within their time, but since then they had been gradually losing more and more time, until at length there was a difference of two hours between the time they ought to arrive and the time they really arrived. This has been the cause of great inconvenience, and in Scotland particularly; in consequence of this irregularity, a day was lost in the return of the post. He did not throw blame on any one; he did not know on whom the blame, if there was any, rested. He had merely stated facts which he was prepared to prove before the Committee, if it were granted. Under these circumstances he would content himself with moving for the Committee in the terms of his notice.

Mr. F. Baring said he doubted whether the subject embraced by the motion of the Hon. Member was of sufficient importance to deserve investigation at the hands of the House. The House must recollect, that in the commencement of so great an undertaking they must naturally expect some accidents; and he thought that it was scarcely worth the attention of the House, under the circumstances, either to pass censure upon, or to take means to ascertain, the causes of these accidents. One sub-

ject connected with the conveyance of the mails by Railroads was under the consideration of the Government, and became, in his opinion, a very serious question, and one which ought to be brought before a Committee of that House, for the purpose of taking their opinion upon it. The House would observe, that the moment the mails were conveyed by the Railways, from that moment they put down the mail coaches, and they would be left in this situation, that the proprietors of the Railways would have an entire monopoly of the road. There would be no possible means of any thing like competition, and of thereby meeting the demands which they might choose to make. He did not wish to make any invidious observations, nor was he connecting this subject with the Railway in question; but cases might occur, and must occur before long, of the nature he had stated, and he thought it was a fair subject for the consideration of the Committee of that House to inquire what means should be taken, and what power given to the Government for the purpose of procuring for the public the use of those Railroads which by Act of Parliament were allowed to be constructed. With this view he would, on a future occasion, propose the appointment of a Committee on this subject, if the Hon. Member for Greenock would have no objection to withdraw his present motion.

Mr. Wallace said he was extremely gratified with the announcement of the Hon. Gentleman, and would gladly acquiesce in his suggestion.

The motion was then withdrawn.

Petitions on Private Bills.

On the motion of Lord J. Russell it was resolved, that no Petitions or Private Bills should be received after Monday, the 5th of February; and that no Private Bill should be read a first time after Monday, the 26th of March; and that the House should receive no Reports on Private Bills after Monday, the 11th of June.

Friday, Nov. 24.

Mr. Guest intimated, that on an early day he would call attention to the orders of the House regarding Railway Bills

LAW PROCEEDINGS.

The Queen v. the London and Birmingham Railway Company.—In this case a rule had been obtained to show cause why a *mandamus* should not be issued to the defendants, commanding them to set out a road according to the provisions of the Act under which the defendants were authorized to proceed with their works. The defendants had diverted a part of a road lying between Stanmore and Uxbridge, and it was stated that the road they had made was not so convenient as the old road. There were two clauses in the Act relating to this matter; one as to diverting a road for a temporary, the other as to diverting it for a permanent purpose. In the first of these cases the new road was expressly directed to be made as convenient as the old road. There was no such express direction with respect to the permanent road. In the present instance it was stated in the affidavits on which the rule was obtained, that the former road was forty feet wide, that the hard road itself occupied twenty-two feet, that there were three feet of footway, and fifteen feet of greensward, and that there was no greensward on the sides of the new road, though it was absolutely necessary that there should be some for the cattle which had to pass along and be upon the road. On the other hand, it appeared that the hard road was now wider than it had formerly been, and it was argued, that as there had been no express direction with respect to the permanent roads being exactly the same as the old roads, this rule could not be maintained.

Sir W. Follett and Mr. Channell were heard against the rule, and the Attorney-General appeared to support it.

The Court made the rule absolute.

LIST OF PATENTS GRANTED BETWEEN THE 2nd AND 28th NOVEMBER, 1837, BOTH INCLUSIVE.

Joseph Whitworth, of Manchester, in the county of Lancaster, Engineer, for his invention of "Certain Improvements in Locomotive and other Steam Engines."—2nd November; 6 months.

Richard Burch, of Heywood, in the county of Lancaster, Engineer, for his invention of "Certain Improvements in Manufacturing Gas from Coal."—2nd November; 6 months.

Joseph Lockett, of Manchester, in the county of Lancaster, Engraver, for "Certain Improvements in the Art of Printing Calicos and other Fabrics of Cotton, Silk, Wool, Paper, or Linen, separately or intermixed; being a communication from a foreigner residing abroad."—2nd November; 6 months.

James Gowland, of Leathersellers Buildings, in the parish of Allhallows in the Wall, within the city of London, Watch and Chronometer Maker, for his invention of "A certain Improvement, or certain Improvements in the Mechanism of Time-keepers."—2nd November; 6 months.

Richard Joshua Tremonger, of Wherwell, in the county of Hampshire, Esq., for his invention of "An Improved Spring, or Arrangement of Springs for Wheel Carriages."—4th November; 6 months.

John Upton, of New Street, Southwark Bridge, in the county of Surrey, Engineer, for his invention of "An improved Method or Methods of generating Steam Power, and applying the same to Ploughing, Harrowing, and other Agricultural Purposes, which Method or Methods is, or are also applicable to other Purposes to which the power of Steam is, or may be applied."—4th November; 6 months.

Ernest Adolph Ortman, of Stockholm, in the kingdom of Sweden, now of Ebenezer Place, Limehouse, in the county of Middlesex, for his invention of "A Method, or Methods of freeing, or wholly or partially, wooden or other porous vessels from certain foreign Matters or Substances which they are liable to absorb, and of turning to a useful account the foreign Matters or Substances so liberated or extracted."—4th November; 6 months.

George Deakin Midgley, of the Strand, in the county of Middlesex, Chemist, and John Howard Hyan, of Cheltenham, in the county of Gloucester, Esq., for their invention of "An improved mode of extracting or obtaining Ammoniacal Salts from liquor produced in the Manufacture of Coal Gas."—4th November; 6 months.

William Arthur, of Glasgow, North Britain, Machine-Maker, for his invention of "Improvements in Spinning Hemp, Flax, and other Fibrous Substances."—4th November; 6 months.

Tobias Michell, of Kingsland Green, in the county of Middlesex, Gentleman, for his invention of "Improvements in Washing or Purifying Smoke and Vapours evolved from Furnaces of various Descriptions."—7th November; 6 months.

Thomas Hughes, of High Holborn, in the county of Middlesex, Truss Maker, for his invention of "An Improvement in Stocks, Cravats, or Stiffners."—7th November; 6 months.

Charles Francais Edward Dulas, of 38, Grande Rue Verte, Paris, in the kingdom of France, but now of Cockspur Street, in the county of Middlesex, Gentleman, for "A New and Improved Method of Cutting and Working Wood by Machinery; being a communication from a foreigner residing abroad."—7th November; 6 months.

John Potter, of Amoats, near Manchester, in the county of Lancaster, Cotton-Spinner, for his invention of "An Improvement or Improvements in the Process of Preparing certain Descriptions of Warps for the Loom."—9th November; 6 months

James Slater, of Salford, in the county of Lancaster, Gentleman, for his invention of "Certain Improvements in Steam-Engines, and also in Boilers and in Furnaces used for the Generation of Steam, or other useful Purposes."—9th November; 6 months.

Charles Royr Williams, of Liverpool, in the county of Lancaster, Gentleman, for his invention of "Certain Improvements in the Manner of Preparing the Vegetable Material of Peat Moss, or Bog, so as to render it applicable to several useful Purposes, and particularly for Fuel."—11th November; 6 months.

Henry Crosley, of Hooper Square, in the county of Middlesex, Civil Engineer, for "Improved Means to be employed in Manufacturing Beet-Root and other Vegetable Substances, for the purpose of obtaining Saccharine Matter therefrom; being a communication from a foreigner residing abroad."—11th November; 6 months.

Hamer Stansfeld, of Leeds, in the county of York, Merchant, for "Certain Machinery of a Tappet and Lever Action, to produce a Vertical or Horizontal Movement, through the medium of Ropes or Bands working over, under, or round Pulleys; being a communication from a foreigner residing abroad."—14th November; 6 months.

William Coles, of Charing Cross, in the county of Middlesex, Esq., for his invention of "Improvements in Gunnery and in Gun and other Carriages, and in the means of connecting the same."—14th November; 4 months.

Robert White, of Nottingham, Lacemaker, for his invention of "Improvements in the Manufacture of Ornamental Lace."—14th November; 6 months.

Robert Whitfield, of Hercules Buildings, Westminster Road, in the county of Surrey, Gentleman, for his invention of "A Composition which he denominates an Indelible Safety and Durable Black Fluid Writing Ink."—14th November; 6 months.

John Jeremiah Rubeni, of Birmingham, in the county of Warwick, Umbrella Manufacturer, for "Certain Improvements in the Manufacture of Part of the Furniture of an Umbrella; being a communication from a foreigner residing abroad."—14th November; 6 months.

Joseph Birch Mather, of Nottingham, Mechanic and Setter-up of Hosiery Frames, for his invention of "Certain Improvements in Machinery employed in Manufacturing Hosiery Goods, or what is commonly called Frame-work Knitting."—14th November; 6 months.

William Male Clay, of West Brunswick, in the county of Stafford, Manufacturing Chemist, and Joseph Denham Smith, of St. Thomas's Hospital, in the borough of Southwark, Student in Chemistry, for their invention of "Certain Improvements in the Manufacture of Glass."—16th November; 6 months.

William Herepath, of the city of Bristol, in the county of Somerset, Philosophical Chemist, and James Fitchew Cox, of the same place, Tanner, for their invention of "Certain Improvement or Improvements in the Process of Tanning."—16th November.

William Fourness, of Leeds, in the county of York, Painter, for his invention of "A certain Improvement or Improvements in Ventilating Pits, Shafts, Mines, Wells, Ships' Holds, or other confined Places."—16th November; 6 months.

James Buckingham, of Miners' Hall, Strand, in the county of Middlesex, Civil Engineer, for his invention of "Certain Improvements in the Means of Ventilating Mines, Ships, and other Places, and an Apparatus for effecting the same."—16th November; 6 months.

Thomas Birch, of Manchester, in the county of Lancaster, Machine-maker, for his invention of "Certain Improvements in Carding Engines, to be used for Carding Cotton and other Fibrous Substances."—18th November; 6 months.

Elisha Haydon Collier, of Globe Dock Factory, Rotherhithe, formerly of Boston, North America, for his invention of "Certain Improvements in Machinery, applicable to the raising Fluids and other Bodies."—21st November; 6 months.

Christopher Nickels, of Guildford Street, Lambeth, in the county of Surrey, for his invention of "Improvements in Embossing or Impressing the Surfaces of Leather and other Substances, applicable to various Purposes."—21st November; 6 months.

Elisha Wykde, of Birmingham, in the county of Warwick, Engineer, for his invention of "Certain Improvements in Locomotive and other Engines."—21st November; 6 months.

James Matley, of the city of Paris, in the kingdom of France, and of Manchester, in the county of Lancaster, Gentleman, for his invention of "Certain Improvements in Machinery for the Operation of Tiering used in Printing Cotton, Linen, and Woollen Cloths, Silks, Papers, and other articles and substances to which Block Printing is or can be applied."—23rd November; 6 months.

James Jamieson Cardes, of Idol-lane, in the city of London, Merchant, for his invention of "An Improved Mortar for Dressing Rough or Paddy, or Redressing."—25th November; 6 months.

Henry Purser Vaile, of Oxford-street, in the county of Middlesex, Civil Engineer, for his invention of "Improvements in Rails for Rail-roads."—25th November; 6 months.

Richard Tappin Claridge, of Salisbury Street, Strand, in the county of Middlesex, Gentleman, for "A Mastic Cement or Composition applicable to Paving and Road-making, covering Buildings, and the various Purposes to which Cement, Mastic, Lead, Zinc, or Composition are employed; being a communication from a foreigner residing abroad."—25th November; 6 months.

Samuel Cocker, of Porter Works, Sheffield, in the county of York, Manufacturer, for his invention of "Improvements in Making Needles."—25th November; 6 months.

Thomas Moore, of Ison Green, in the county of Nottingham, Lace Manufacturer, for his invention of "Improvements in Machinery for Frame-work Knitting."—27th November; 6 months.

Samuel Draper, of Basford, in the city of Nottingham, Lace Manufacturer, for his invention of "Certain Improvements for producing Ornamental Lace or Wearings."—27th November; 6 months.

John Dover, of Thames-street, Merchant, and William Jones, of Bartholomew Close, Chemist, both in the city of London, for their invention of "Improvements in Filtering Fluids."—28th November; 6 months.

STEAM NAVIGATION.

Iron Vessels.—We noticed, a short time ago, the arrival at Alexandria (after a passage of eighteen days steaming from Liverpool) of the iron steam yacht, *l'Egyptien*, constructed at the Birkenhead iron-works. Letters have, we understand, been received respecting her by the last Malta packet stating, that she had made two voyages from Alexandria to Candia with government despatches, and was afterwards tried on the Nile, under the direction of one of the Pacha's admirals, attended by a number of officers, whose report of her qualities were so satisfactory, that, on the 17th September, the Pacha and his suite embarked on board her, and proceeded up the Nile to Cairo. The voyage of this vessel out to Alexandria, and the fact of her having been twice subsequently employed to convey government despatches on a passage of considerable length and difficulty, prove that the compass on board her acts with perfect accuracy, and that iron vessels can be constructed of sufficiently light draft of water to render them suitable for the navigation of shallow rivers with the model and strength of sea-going steamers.—*Albion.*

The Great Western Steam Ship is now in the East India Dock having her engines put on board, which are manufactured by Messrs. Maudsley and Co. The four immense boilers are already fixed, also several portions of the engine. The weight of each paddle-shaft, after being turned, weighs 6½ tons, and the intermediate shaft 4½ tons: their respective diameters are 18¾ and 17½ inches; they were forged at Messrs. Accerman's Bristol Iron-works. The state cabin is to be fitted up in the very first style of elegance; no expense is to be spared to render the vessel commodious and suitable for passengers.

The Semiramis War Steamer has been fitted out for immediate service for the East India Company.

New South Wales.—Steamers are much wanted at this colony: there is one only, which makes more than 200*l.* per week.

Practice v. *Theory.*—The Aire and Calder Navigation have lately suffered an immense loss, from the failure of two powerful boats, the *Vanguard* and *Jason*, built to navigate the shallows of the Humber, in the trade between Goole and Hamburgh. The two vessels were built under the direction of the Company's land-surveyor, from a *model;* but when afloat, to the consternation of all parties, were found to draw as much water, without their lading, as rendered them useless. They were built at Glasgow, and have powerful engines: they lie in the East India Docks—*as models!*

Practice v. *Theory: Incrustation of Boilers.*—When Dr. Lardner was lecturing in Hull last autumn, he remarked largely upon the loss of steam from incrustation, by saline deposit in the boilers of marine engines, and proposed, as an effectual remedy, the substitution of copper for iron; the copper, as he alleged, having a detergent power, and not being a recipient of deposit. An operative, who listened, begged the learned Doctor to accompany him to the Hull Docks, where he produced a copper pipe so fully incrusted, and so closely adhered to the saline incrustation, that it withstood the blows of a chisel and sledge hammer used to separate it. Dr. Lardner has subsequently made the discovery public in some official reports; but we have not seen it in any other form. As the former opinion was frequently propagated by lectures on Steam Navigation to India, and others given by Dr. Lardner, we think that the mistake should be published, and the lovers of science be practically informed without delay.

Steam Communication in Austria.—The Emperor of Austria is giving every possible encouragement to railroads and steam-navigation in his part of Germany. He has lately directed the bridge of Vienna over the Danube, which, from the lowness of the arches, has been hitherto an obstruction to the navigation of that river, to be so altered as to allow the steam-boats to pass under it, and this at the public expense. This bridge was the chief obstacle in the way of communication between Vienna and Lentz hitherto.—*Morning Herald.*

ENGINEERING WORKS.

RAILWAYS.

South Eastern Railway.—The contractors have commenced the works at Shakspeare's Cliff, near Dover, where the cliff is very high and exceedingly rugged. A double tunnel is to be cut through the cliff, and formed out of the solid chalk with Gothic pointed arches. There are to be shafts for ventilating, and side galleries cut from the Tunnel to the side of the cliff on a level, to facilitate the removal of the excavations, which are to be shot over on to the sea beach below. W. Cubitt, Esq., is the engineer under whose directions the works are to be executed.

Greenwich Railway.—We are happy to find there is more activity now shown for the finishing of the remainder of the railway than there has been for some time since. We trust that the Directors will proceed with vigour, and will put their *railway in order.* We suggest, that if the roadway was levelled on the side of the arches for a mile from Tooley Street, and the arches made impervealble to wet, which can be easily done, a rental might be very soon raised, and the arches converted to some useful purposes; if not for houses, they might be adapted for manufactories, warehouses, &c.; we are convinced that the street would soon become a very great and leading thoroughfare to Rotherhithe, Deptford, and Greenwich, and greatly improve the neighbourhood.

London Grand Junction Railway.—We understand the Directors of this Company issued 150 writs in one day for the enforcement of the calls. What use is it for the Directors making any further calls, or attempting to proceed with the works, until they obtain a new Act of Parliament for an extension of the time for purchasing the property and making the railway? It appears to us morally impossible that the property can be purchased within the time allowed by their present Act.

Leith and Edinburgh Railway.—This railway is begun, and some progress made in the cutting and embanking.—*Edinburgh Courant.*

North Union Railway.—The works on this line are at present making rapid progress at the Wigan end. The erection of two iron bridges, one over Walgate, and the other over Chapel, are now in progress, and they are expected to be an ornament to that town.—*Preston Chronicle.*

Railway over Morecambe Bay.—Great interest has been excited by Mr. Stephenson's survey of the country between Lancaster and Whitehaven, with the view to he formation of a line of railway. We understand the project of the embankment of Morecombe Bay is viewed with much interest by a great many influential gentlemen in the metropolis.—*Preston Pilot.*

Brighton Railway.—The public will soon be able to form a more decided judgment on this undertaking than they have been able to do. The united Committee, after having encountered much difficulty, have at length put things in a favourable train; they have been joined by the shareholders of the whole of the different lines, and although five places are vacant in the direction, by the retirement of Stephenson's portion of it, these will, in due course, be filled up by most influential and respectable gentlemen. A report on the direct line will be presented at the end of this month by Sir J. Rennie and Mr. Rastrick, and which, we are assured, will fully clear up whatever doubts may at present exist as to this being the only line of rail and which can be carried into effect consistently with the interests of Brighton.—*Brighton Herald.*

Manchester and Birmingham Railway.—We are authorized to state, that, in the event of the Manchester and Sheffield Railway being abandoned, it is the intention of the directors of this company to consider carefully the best means of connecting, by a desirable branch, Ashton-under-Lyne and Stalybridge with their intended main line, so as to give to that important and extending district the benefit of a railway communication with Manchester.—*Manchester Guardian.*

Midland Counties' Railway.—At a full meeting of the directors of the Midland Counties' Railway, held at Loughborough, on Tuesday, the contracts for the whole of the line from Leicester to Rugby were let to that eminent contractor, Mr. Mackintosh, of London, who has engaged to have the works completed in two years and a half, from the 1st of November. As the heaviest portions of the work are in this line, it is supposed that the entire line will be open in three years at the most from the present time. The works between Nottingham and Derby are in a course of rapid progress, and it is expected that that part of the line will be opened in little more than a year.—*Mining Journal.*

Railway from London to Glasgow, via Carlisle, Dumfries, &c.—Spirited meetings have been held, and resolutions come to, on this subject, along the Glasgow line, from Dumfries to Kilmarnock. The course adopted is just what is required; and, no doubt, if the members of the Committee act with spirit, the survey will not be long in being got. The Town Council of Kilmarnock have moved in the matter, and appointed a Committee to procure the necessary subscriptions. A public meeting is also about to be held in Annan on the subject; so that little fear need now be entertained that the proposed survey will not be obtained. We regret that, in some parts of our own town, considerable dilatoriness has been shown in pushing the subscriptions; and, in looking over the subscriptions, we observe a number of respectable names—some of them public men, too—who have not yet subscribed. We trust the subscription-list will not long remain in that state. And there are several enterprising and influential proprietors interested in the district and line whose names are not in the list. We fear there is not a little neglect in several quarters. Now is the time for all parties to remedy the evil. We again say to the inhabitants in the whole line, be up and doing.—*Dumfries Times.*

Pincock Bridge—The Railway.—The bridge at Pincock, over which passes the high road hence to Wigan, and which, as we stated in our last publication, had suffered materially from the eruption of the waters from the railway embankment above, has given way on the south arch and abutment. It is considered in so dangerous a state, that our townsman, Mr. Woods, stone-mason, who yesterday inspected it (on behalf of Mr. Dewhurst, the bridge-master, who is ill), immediately railed it across to prevent carts or other carriages from passing. Should it fall, a temporary bridge of balks will be constructed to serve during the winter. We understand that it is in contemplation to build a bridge in lieu of this, a little higher up the valley, and we would suggest that, whether it be rebuilt on its present site, or elsewhere in the valley, it should be of greater elevation, and mounded up so as to reduce the acclivity on either side. We learn that about 140 men are employed, at the fallen railway bridge above, in removing the materials so as to come at the foundation for a new bridge. The bridge will, we are further informed, be, in the first instance, constructed of wood, so that the embankment may be carried over without loss of time; and a stone bridge will be thrown over, within the frame-work of the temporary structure, after the superincumbent materials of the embankment have become settled and compacted. —*Preston Observer.*

Bristol and Exeter Railway.—The Bristol and Exeter Railway contract, No. 1, commencing at Pile-hill, near Bristol Iron Bridge, has been begun. In a few months that part of the line from Bristol to Weston-super-Mare and Bridgewater will be finished, as several miles of contracts, Nos. 2 and 3, are completed. This line of road is a continuation of the Great Western, by the union of the two lines in Temple Meads; and the inhabitants of Bath will, by next summer, be conveyed to Weston-super-Mare in one hour, being a distance of 30 miles.—*Western Luminary.*

London and Greenwich Railway.—The number of passengers conveyed on this line, without the slightest accident, from November 12th to the 16th, is 17,940, and the amount received 454*l.* 5*s.* 0*d.*, which, with 8*l.* 5*s.* 0*d.* from the footpath, makes a revenue, in five days, of 462*l.* 10*s.* 0*d.*

Lancaster and Preston Railway.—Mr. Locke, the engineer, paid us a visit last week, and at his instance the whole line of railway has been re-measured, and some slight variations and improvements have been determined on. We understand the plans for the owners of property on the line are now mostly made out, and that the directors are engaged in negotiations for the purchase of land with the various owners through whose property the railway is intended to pass.—*Lancaster Guardian.*

Longridge Railway.—The Annual Meeting of the shareholders of the Longridge Railway was held on Saturday last at the Town Hall. The business transacted was brief but gratifying. A short report was read, by which it appeared that such progress had been made in the formation of the line as gave assurance of its completion at no distant period. The utility of this railway, and its increasing prospects of success, may be learned from the fact, that not only is the demand for stone from the Longridge Quarries in great requisition for this town and neighbourhood, but for Liverpool and other remote places. The difficulty of conveying it, owing to the state of the common roads, has latterly been great. Some blocks of stone, of six yards in length, and ten tons in weight, have recently been sent to Liverpool, for, we believe, columns for a large public building; and for these, carriages have been sent from that town, there being none here of sufficient size to convey them. By the railway, stones of any required dimensions may be brought down.—*Preston Observer.*

Railway from Glasgow to Carlisle.—It is said that Mr. Locke is at present engaged in a survey to discover a line of railway from Glasgow to Carlisle, as well as between the latter city and Edinburgh. Mr. L. is reported to be perfectly satisfied of the practicability of the Shap Fell Line, and that he prefers it to the line through West Cumberland. Mr. Locke may have traversed the route of the Western line, but, judging from his report, we should have no hesitation in saying, that he had never either passed through the district, or dreamt of an opening in that direction previous to the publication of that document. Report says, that the gentlemen of Penrith intended shortly to call a public meeting in support of a line of the railway over Shap Fells.—*Cumberland Pacquet.*

Glasgow, Paisley, and Greenock Railway.—We perform a very gratifying duty in again directing public attention to the progress which is now making towards the execution of the railway between this town and Glasgow. The name of Mr. Joseph Locke as engineer, gives the best assurance of the speedy and masterly execution of the work, which, we understand, will be commenced with vigour, at various parts of the line, so soon as the weather will permit. We may thus hope to see part of it open within a short time, and the whole line completed in little more than two years. This we hold to be a subject of sincere congratulation to the west of Scotland generally, and to the dwellers on the Clyde in particular. Our railroad is the first link in the connecting chain of rapid communication throughout Scotland from west to east, and we cannot conceive any work better calculated to insure great and certain advantages to all concerned. A railroad, 22 miles in length, without one engineering difficulty, with one terminus in the centre of Glasgow, and the other at the Harbours of Greenock, passing through the very midst of Paisley and Port Glasgow, and bringing all these important and populous towns into immediate connexion with each other; such is the "Glasgow, Paisley, and Greenock Railway," and we doubt if, there is another district so favourable for such a purpose in the whole world of business and of bustle.—*Greenock Advertiser.*

West Cumberland.—The proposed line of railway bearing this title, is intended to be a line of connexion between Lancaster and Carlisle *via* the western coast of Cumberland. Mr. Stephenson, who was employed to survey the country along which it is proposed to run, has reported favourably of it, giving his opinion that it affords every facility for railway communication. Lord Lonsdale has written to the projectors, stating his concurrence in their views with respect to that portion of the line connecting Whitehaven with Maryport, and expressing his willingness to forward them; and with respect to the more extended line to Lancaster, his lordship says, he is not prepared at present to give any opinion. The Whitehaven Committee have addressed the Lords of the Treasury, requesting them to employ government engineers to survey the proposed Grand Junction line in order to ensure a good and safe railway and test the practicability of an embankment across Morecambe Bay.—*Globe.*

Great North of England Railway.—A contract for the formation of a considerable portion of this line of railway, south of Darlington, was let on Tuesday, the 31st October, and will be forthwith commenced.—*Sunderland Herald.*

Edinburgh and Glasgow Railway.—A meeting of the shareholders of this undertaking was held on Wednesday, 9th November, at Edinburgh, the Lord Provost in the chair, to lay before them an account of the proceedings of the directors, and to consider what measures should be now adopted. The chairman said, he hoped that there was but one opinion among the subscribers, as to the propriety of persevering in the endeavour to procure the sanction of parliament to their project, as he knew of no public measure that would be of more utility to Scotland. The secretary then read the report, which detailed the steps taken last session with a view to procure the act. The report stated, that the bill, after it had passed the Commons, and the standing orders of the House of Lords, had been stopped further progress by the dissolution of parliament, consequent upon the demise of the crown. The shareholders were recommended to contribute one pound a share further, to enable the directors to proceed with the bill in the ensuing session, as the funds were exhausted. A large number of the shareholders, it was mentioned, had already agreed to the proposal for another call. A series of resolutions were agreed to unanimously, in furtherance of the object of the company: several of the movers impressed upon the meeting the propriety of the shareholders keeping together and acting in a united and determined manner in all their proceedings. Mr. Sandford thought that the bill would be allowed to proceed under the old standing orders, by which means it would be passed *pro forma* through the House of Commons, and be taken up at the stage at which it was stopped on the dissolution of parliament. In reply to a question on the subject, it was stated to be the intention of the directors to proceed with a renewed application for the bill, should they not succeed in their attempt in November to get the bill forwarded as they expected.—*Railway Times.*

Aylesbury Railroad.—Active preparations are about to be commenced for laying down a line of railway from the town of Aylesbury, to join the London and Birmingham line at Cheddington, near Marsworth. The distance is computed at about seven miles, and from the very level state of the ground it is thought that the expense will be trifling compared with the enormous outlay of money which some branch railways require.—*Railway Times.*

North Midland.—This line of railway, betwixt Chesterfield and South Wingfield, is in a very forward state; and preparations are making to commence the contracts between Stalforth-lane, through Chesterfield to Staveley. Clay Cross Tunnel is now progressing with spirit. Six steam-engines for the purpose of pumping water and drawing earth are in constant work. The whole of the tunnel being in coal measures, is considered to be favourable to the undertaking; and although the influx of water is considerable, yet it is certainly not greater than was anticipated. From fifty to sixty yards of the tunnel has already been bricked in. The work, which progresses night and day without intermission (Sundays only excepted), is carried on by what is called "lengths" of four yards each at a time. When the miners have cleared away the earth, the required space (four yards), they remove to another part, and bricklayers take their places. The inverted part of the arch, and the side walls, are about eighteen inches in thickness; the top arch is twenty-seven inches thick generally, but it is a little varied according to the nature of the ground. The whole of the bricks are laid in Roman cement. The make of bricks last summer was about four-and-a-half millions; next summer it is intended to make seven millions; and the summer following four or five millions. The tunnelling can be proceeded with at ten different places at the same time, viz., by five sets of miners and five sets of bricklayers, alternately changing places. There are about ten or a dozen miners in a set, and if the work is tolerably dry overhead, they continue at work twelve hours, when a fresh relay of men take their places; but if much water drains on the men from the roof of the tunnel, they work only [illegible] hours at a time. The [illegible] miners are at the rate of about 8d. per hour. A set of miners (meaning here the double or treble set, to bring round the twenty-four hours) can excavate a four-yards length in about nine days, under ordinary circumstances, and this can be done, as has been before observed, at five places at the same time, which is at the rate of about fifteen yards per week, or about 780 yards per year; and as the tunnel is to be 1800 yards in length, it will, of course, take about two years and a half from the present time to complete it. We are aware that the contractors have engaged to finish it by the 1st of May, 1839; but this is considered to be impossible. A great many hands are employed on the deep cuttings of each end of the tunnel, and so large a congregation of course renders cottages and lodgings very scarce and dear at Clay Cross and the neighbourhood. This scarcity of cottages and lodgings has caused about thirty houses, or rather cabins, to be built with sods in the neighbourhood; and notwithstanding this great mart for human labour, troops of men are daily applying for work, who cannot obtain any.—*North Derbyshire Chronicle.*

Durham Junction.—The magnificent viaduct, which is now being erected over the valley of the river Wear by the Durham Junction Railway Company, is almost finished. When completed, taking the span of the different arches and the immense height into consideration, it will eclipse in grandeur any bridge hitherto erected in the United Kingdom. It consists of four large arches, and six smaller ones, and is 810 feet 9 inches in length. The principal arch, which is thrown over the bed of the river, is of 160 feet span, and forms almost a semi-circle; there is another arch of 144 foot span, and two of 100 feet span each. The height, from the foundation of the centre pier to the top of the parapet, is 158 feet. The three smaller arches, and the 100 feet arch, on the south side of the river, are completed, and the centering entirely removed.—*Globe.*

FOREIGN RAILWAYS.

Railroads in Belgium.—The line by which the Belgians propose to connect their western boundary, looking on the sea, with their eastern, bordering on Germany, is already so far advanced as to be opened from Tirlemont to Ghent on the 29th of September. When the whole line is completed, the journey by steam-packet and railway, between London and Brussels, will be effected in sixteen hours. Mr. Simons lately visited all the works preparatory for laying down a railroad from Ghent to Bruges; the operation of levelling is finished as far as Beerren, two leagues from Bruges. Mr. S. seems to be sure that the section from Ghent to Bruges may be opened in the month of May, next year, and that from Bruges to Ostend in the month of June following. The railroads now laid down in Belgium cover a length of ground equal to 143,720 metres, or about thirty-six post leagues. A few days ago, the English workmen employed in directing the locomotive engines on the railroad mutinied, in consequence of an order from the administration, that Belgian workmen should be taught how to direct the machines. The arrest of one or two of them, who refused to direct the trains, speedily restored order amongst the rest; and to do away with their apprehension of losing their situations, as soon as a sufficient number of Belgian workmen were able to supply their places, the administration has since entered into an engagement with them, which can be broken only under circumstances of gravity, and which have been previously specified.

Prussian Railroad.—The cost of the railroad to be constructed from Strasburg to Basle is estimated at twenty-five millions of francs. The subscription in the two cities already amount to nearly sixty millions of francs.—*Mining Journal.*

Berlin.—The manufactories of Berlin have greatly increased within these few years. At present a very extensive cotton-manufactory is erecting by one of the richest citizens of Berlin; a powerful steam-engine is to be used also to work a steam-mill. The quantity of Prussian manufactures sold at the great fairs is constantly increasing, and the manufacturers of Berlin are now so flourishing, that several of the larger ones employ 1000 workmen.—*Suabian Mercury.*

Foreign Patronage of Railways.—General Scheff'king, aide-de-camp to the Emperor of Russia, accompanied by a young Russian *savan*, has just made a tour in the north of England, by order of his sovereign, to make himself acquainted with the construction of the railroads and the locomotive-machines. We are assured that immense railroads are about to be laid down in Russia, for which machines are to be purchased from the manufactories on the Tyne and the Wear. A similarly great work in the north of Germany is on the eve of being commenced.—*From No. 1 of a New French Journal, published in London, under the title of "Le Miroir de Paris."*

Foreign Railways.—The head-quarters of the Belgian railway engineers are now transferred to Liege, where a building of some consequence has been purchased by the Government for their accommodation, to enable them to superintend more conveniently the continuation of the great national line of railway to the frontiers of Prussia. The meeting of the Prussian and Belgian lines will take place in a tunnel on the frontier, and the line is already marked out by signal posts from this place of meeting to Cologne. Great activity prevails in the preparations for the Austrian line from Vienna to Gallicia through Moravia, which will avoid the mountains of Auspitz and Austerlitz, but will have to encounter some difficulties in passing through the defiles near Neu-Titschin. The success of the railroads already opened abroad, appears to be quite satisfactory. On the first day of the opening of the first railway direct from St. Petersburgh, the number of passengers was only 1668, and only ten journeys were made, but the numbers rapidly increased. On the fifth day there were twelve journeys, and 4081 passengers, and the receipts for the first five days were 21,155 rubles 40 kopeks, or nearly £900 sterling. In Belgium, the Government have given orders to double the number of locomotives now on the rail.—*Railway Times.*

Naples, Oct. 29.—The railroad from this city to Castellamare will be commenced in the month of November. M. Bayard, of Paris, the contractor, arrived here several weeks ago.—*Morning Chronicle.*

American Railroads.—A singular and wonderful feature of America is her vast and increasing extent of railroads—while the English have almost stood still, contemplating with great complacency the two or three which they have made—the Americans have laid down 2000 miles of railroads, many of them as good, for all practical purposes, as the Liverpool and Manchester. Many circumstances conspire to assist the Americans in the construction of these roads; the alluvial plains, which often present a dead level for a hundred miles together; the great plenty of timber, and, more than all, the non-appropriation of the ground, which enables the projectors to buy it for a trifle, and in the majority of cases to get it for nothing. They have pushed these roads into the very bosom of the wilderness. Like the military roads of the Romans, they hold steadily and straight on through plain and morass, [illegible]

that skirt the banks of the Mohawk; and where a few years since an Indian hunter could scarcely force his way, you now dash along at the fearful velocity of twenty miles an hour. Many of these roads have been finished for less than 5000 dollars a mile; the very best of them, made of English iron, and laid down on stone sleepers, have been completed for 29,000 dollars a mile, or about £6000, which is only one-seventh the cost of the Liverpool and Manchester. The same method and dexterity which marks their steam-boat travelling is also seen here: the engines are nearly all of American construction, having superseded those imported from England, and the engineers seem to have them under better control. There is certainly no unnecessary expense about these railroads. The sleepers are often not filled up, and frequently in passing a deep chasm, or rushing torrent, the bridge is only just wide enough for the rails. Most of these railroads are at present single tracks, which occasion delay when trains meet. The carriages are larger than ours, they are sometimes fifty feet long, and have a dock with verandas. I have often remarked, that American engineers seem more dexterous than English. I have seen a train going seventeen miles an hour stopped in forty yards. The engine carries a large shovel in front, which removes any obstacle lying on the rail. Riding on the engines of a Washington train at night, I saw a cow lying on the rails; before I could exclaim, we were upon her, and I expected a shock, instead of which, the shovel picked her up, carried her a few yards, and then threw her to the road-side, out of the way. I took many opportunities of riding on the engines; wood is burned in most of them, anthracite coal in few. The cylinders are mostly horizontal, like our own; but I saw several where the cylinders were vertical. There is a fine road from Albany, on the Hudson, to Utica, ninety miles. This road, in a few months, will reach to Buffalo, on the lake Erie, and then a traveller may pass from New York to Niagara in twenty-four hours. There are railroads throughout all the New England States to every town of importance, and some thousand miles in progress in the South and west. There is the least improvement in the slave states. There is no country where you can cross such vast tracts in so short a time as in America, and the facilities are every day increasing. The Ohio already joins the Delaware by a railroad 350 miles long; and in a few years a traveller may be able to pass from the Gulf of Newfoundland to the Gulf of Mexico; from icebergs to orange-groves, in six days.—*Leicester Mercury.*

Leeds Water Works.—The supply of water afforded by the present works is from the River Aire, which drains, and stains rather than washes, the feet of the bold eminences upon which Leeds is built. At Leeds Bridge, where the outpourings of dye-houses, fellmongers, and chemical-works, discharge their refuse, stands the present water engine, a lazy old water-wheel, which lifts into elevated reservoirs the mucid quantum of supply, equal to about one gallon per day for each inhabitant, and with this have the population been hitherto content. A bill is now before us which passed during the last session for an adequate supply, and we congratulate the town upon the approaching improvement in its condition. A Leeds correspondent has furnished us with some curious particulars concerning the project, and the Minutes of Evidence before the House of Commons, which are very entertaining. We shall in our next give particulars, and describe the scheme.

Great Viaduct now Erecting over the River Wear, near Sunderland.—This magnificent work, which is for the purpose of connecting the great coal field situated on the right bank of the river Wear, with a harbour to be constructed on the river Tyne by means of the Durham Junction, and the Stanhope and Tyne railways, is advancing rapidly under the excellent management of the enterprising and eminent contractors, Messrs. Gibb and Son, of Aberdeen, and is now attracting much notice in the north of England. This viaduct consists of four large and six small arches. The span of the principal arch measures no less than 160 feet, another 144 feet, and the remaining two 100 feet each. The roadway is about 130 feet above the bed of the river, exceeding by several feet the Cartland Craigs Bridge, near Lanark, and the bridge over the water of Leith, near Edinburgh, erected by the same contractors. Besides the height above the level of the river, the foundation of one of the piers is said to be 40 feet below the level of the water, so that the masonry, from the foundations to the top of the parapet, extends to about 170 feet. This viaduct, whether considered with reference to its great altitude, or the span of its principal arches, is well deserving the inspection of those who take an interest in such matters. The arch over the river has been turned without giving the least obstruction to the navigation. The timber required for centering has been very great; in the great arch alone the quantity is said to be 30,000 feet. The best point from which to view this great structure is on the river about 200 yards either up or down the stream.—*Glasgow Herald.*

Southampton Dock Company.—The Directors have entered into a contract with Mr. Burge for the formation of their Western Dock.

Monck-Wearmouth Docks.—The new Wet Dock, on the north side of the Wear, has been opened in due form. The works consist of an inner and outer dock or basin; the one six and the other one acre and a half in extent; but it can be considerably extended at a comparatively trifling expense, and will accommodate about one hundred sail of large ships.

A Lighthouse is about to be built on Ardglass Pier, in the county of Down.

NEW CHURCHES.

[*We shall feel particularly obliged to Architects in the Country, to forward us the particulars of any New Churches that are building, the Number of Sittings, Dimensions on the Plan; if with Galleries, Vaults, Tower, Turret, or Spire; Brick or Stone Building; Architect's Name, and the Cost or Estimate; also similar information of any Public Buildings that are progressing.*]

A new Church is now erecting at Tunbridge Wells, Kent, from designs by T. Brown, Esq., of Greenwich; the style is Saxon-Gothic, and one of the most beautiful specimens of that unique species of architecture. The walls are faced with brick, with stone dressings; the porch and tower of stone. The Church is intended to accommodate 2,000 persons. The expense is estimated at about £8,000.—*C. L. O.*

A new Church is now erecting at Trowbridge, Wiltshire, under the superintendence of A. F. Livesey, Esq., Architect, of Portsmouth. The style is simple Gothic; the plan is a cross, with a tower at the end of the transcept; the building is to be erected of stone, and to accommodate about 1,200 persons. The cost is estimated at £8,200.—*C. L. O.*

Chesterfield.—A new Church is building in Newbold Lane: the first stone was laid early in the spring, by his Grace the Duke of Devonshire; it is of stone, the extreme length being 103 feet, with galleries on each side, and a square tower: the total height is 84 feet; the style is pointed Gothic; it is to contain sittings for 1,000 persons, and it is estimated to cost, including salary to the Clerk, the sum of £3,361. T. Johnson, Esq., is the architect.—*C. Kinder.*

Trinity Church, Ettingshall, Staffordshire, was consecrated August 23, 1837. The church, schools, and parsonage, were erected from designs by Robert Ebbels, Esq., Architect, of Trysull, Wolverhampton. The buildings are so placed as to form three sides of a quadrangle, and have a peculiar and picturesque effect, forming as it were a little colony of itself; and being built over the mines, they are constructed in half timber, braced and framed together as firm as a ship, and painted black and white in the style of the buildings of Henry VIII. and Elizabeth—a rare occurrence, and we believe the only entire church of that construction in the kingdom. The church is entirely free, except four pews, and contains 920 sittings, including children. There are two tier of galleries at the west end, and the timbers of the roof are shewn and made ornamental, and the whole has a most pleasing effect. The contract for this church alone was £1230.

St. John's Church, Reading, Berks, was consecrated April 28, 1837. It is a Gothic building, the west end of Bath stone, and similar in design to King's College Chapel, Cambridge, with a splendid west window, open battlements, &c. This church contains 897 sittings, 459 of which are free. It was built at the sole expense of the Rev. N. Trench, and the church *alone* cost about £2600. Robert Ebbels, Esq., Architect.

St. Catharine's Church, Ventnor, Isle of Wight, was consecrated July 20, 1837. It is a Gothic building, entirely of stone, and has a most elegant tower and spire, and the interior is extremely chaste. It contains 505 sittings, 179 of which are free. It was built and endowed at the sole expense of John Hambrough, Esq., of Steephill Castle, Ventnor, at a cost of about £3371, *all* expences included. Robert Ebbels, Esq., Architect.

J. Hambrough, Esq. is also having built at his own cost, about £1500, a parsonage-house, in character with the style of the church, from designs by Robert Ebbels, Esq.

July 28, 1837, the corner-stone for a new church at Hawley-Yately, Hants, was laid by Mrs. Dumbleton. This is a small Gothic church, will contain about 320, and one-third of which will be free. It will be ready for consecration *early* this month, December. Robert Ebbels, Esq., Architect.

St. Nicholas Church, Guildford, Surrey. This church was consecrated August 31, 1837. It is a Gothic building, with tower, crocketed pinnacles, &c., the interior shows the timbers of the roof, which are filled in with rich tracery. The church will contain about 1100 sittings, one half free. Cost of church alone about £2500. Robert Ebbels, Esq., Architect.

The church of Enhurst, Surrey, is rebuilding from designs by Robert Ebbels, Esq., Architect.

A new church, Gothic style, tower, &c. is to be commenced immediately at Handsworth, Birmingham, which will contain about 1100 persons, one half to be free. Robert Ebbels, Esq., Architect.

A new Church, Gothic, with tower, &c. is to be commenced immediately (under her Majesty's commissioners), at Tipton, Staffordshire, will contain 1820 sittings. Robert Ebbels, Esq., Architect.

New Church, Lower Rotherhithe.—Holy Trinity. The foundation stone for this Church (being the second of the three churches intended in this extensive parish) was laid October 12. Sampson Kempthorne, Esq., Architect.

Dacre Church, County York.—A new Church has been erected from a plan modelled and designed by a young lady of the neighbourhood.

Barrowfield, Lancashire.—A new Church is about to be erected by subscription.

Clevedon, Somersetshire.—A new Church is to be erected by subscription.

The New Roman Catholic Church in Kendal was opened on the 16th Sept., 1837; it is dedicated to the Holy Trinity. The church is erected in the New Road, and is from the design of Mr. Webster, Architect, of Kendal. It is a fine specimen of the good taste of that talented artist, built in the early Gothic style of architecture. The east front, facing the river, which, to suit the locality of the situation, is the principal entrance, consists of a projecting centre and two receding sides. In the centre is a beautiful doorway, with Gothic columns, and deep moulded arch. Above is an elegant three-light Gothic window, having a neat label and string mouldings, with shields, &c. In the embattled gable there is a handsome niche, canopied, and containing a sculptured limestone group of St. George slaying the Dragon, carved by Mr. Thos. Duckett of this town, a young man rising rapidly into eminence in his profession. The top of the gable finishes with a stone cross. At the extreme angles are projecting octagon buttresses, finished with pinnacles. The receding sides finish at the angles with double square buttresses and handsome moulded caps, and, like the centre ones, surmounted with pinnacles and finials. The ends of all the windows and door labels are finished with carved heads and bosses. The whole of this front is of limestone ashlar. The edifice is a beautiful object from all parts on the east and south sides of the town. The other fronts of the chapel, which are, in a great measure, concealed by other buildings, are of a coarser description, but at the same time neat and substantial.—*The Interior.* The principal entrance leads into a vestibule which connects this entrance with both the body of the chapel and the gallery. On leaving the vestibule, the eye is immediately attracted by the altarpiece at the further end of the chapel, which is a beautiful piece of workmanship. The altar is situated upon a flight of steps, under an archway or alcove. This archway is composed of thirteen columns and rib-mouldings, whilst the intermediate spaces are filled with rich tracery, niches, &c. &c. The archway, in front, is finished with crocketed label and finials, flanked with columns, niches, pediments, and crocketed pinnacle finials. At the back of the alcove rises a handsome and well-executed stained-glass window with three lights, which throws a sombre, but yet suitable light upon the altar, tabernacle, and screen. On each side of the tabernacle there are six niches canopied, in which are placed figures of angels with hands joined in the attitude of prayer. The ceiling is in perfect keeping with what we have described. It displays tasteful work, and is covered at the intersections of the mouldings with bosses, &c. Large pendants hang from the centre, and the effect is magnificent. The walls are stuccoed in imitation of stone, with ornamental label to the windows. At the west end there is an

organ of very large dimensions, built by Mr. John Davis, of Liverpool. As a whole, the interior of this edifice may be considered as a first-rate work of art, and will no doubt secure the admiration of all who have an opportunity of examining it. It is calculated to accommodate from 600 to 700 people, and will cost about £2,500.

———

BUILDINGS AND PUBLIC IMPROVEMENTS.

Malibran.—M. Beriot's Monument to Malibran in the cemetery at Laken, as designed by Geef, is described to be a rectangular chapel, surmounted by a cupola and cross. A single door is to admit the light of day to penetrate the interior. A fountain is also mentioned; and the vision of the spectator will only catch an indistinct and mysterious view of a pure marble statue of Malibran, as she appeared in the 5th act of "Norma,' after she had cast off the Royal mantle, and stood with a poetic expression of exaltation and grief, in garments of white.—*Literary Gazette.*

Oxford.—New Courts of Justice are about to be built under the direction of —— Ploughman, Esq., Architect, the successful competitor.

Derby.—A spacious Literary and Scientific Institution, to be called the Athenæum, together with an extensive Hotel, is about to be built under the direction of —— Wallace, Esq., Architect, the successful competitor.

New Street from Holborn-bridge, opposite Farringdon-street, to Clerkenwell-green.—Notices have been given, that an application will be made to Parliament in the present session, for an act to authorise the City authorities to form the above street.

New Street from the New Houses of Parliament to Pimlico.—Notices have been given by order of the Commissioners of Her Majesty's Woods, &c., that an application will be made in the present session for an act to form the above street.

Carriage Paving.—A new method is being adopted on the ascent from Tooley-street to London-bridge; the granite paving is laid in parallel courses with an interstice of two inches between, which is filled up within two inches of the top with two-inch slates, thereby leaving parallel grooves two inches wide and two inches deep, which it is supposed will give the horses a firmer foot hold

THE ELECTRIC TELEGRAPH

A MODEL to illustrate the nature and powers of this machine was exhibited on Wednesday evening, 15th November, at a very full meeting of the Society of Arts (Edinburgh), Sir John Graham Dalyell in the chair. Accidental circumstances prevented us from being present, but we have since had an opportunity of examining it, and seeing it in operation The model consists of a wooden chest about five feet long, three feet wide, three feet deep at the one end, and one foot at the other. The width and depth in this model are those which would probably be found suitable in a working machine, but it will be understood that the length in the machine may be a hundred or a thousand miles, and is limited to five feet in the model merely for convenience. Thirty copper wires extend from end to end of the chest, and are kept apart from each other. At one end (which, for distinction's sake, we shall call the *south* end) they are fastened to a horizontal line of wooden keys, precisely similar to those of a piano-forte; at the other, or *north* end, they terminate close to thirty small apertures equally distributed in six rows of five each, over a screen of three feet square which forms the end of the chest. Under these apertures on the outside, are painted in black paint upon a white ground, the 26 letters of the alphabet, with the necessary points, the colon, semicolon, and full point, and an asterisk to denote the termination of a word. The letters occupy spaces about an inch square The wooden keys at the other end have also the letters of the alphabet painted on them in the usual order. The wires serve merely for communication, and we shall now describe the apparatus by which they work.

This consists at the south end of a pair of plates, zinc and copper, forming a galvanic trough, placed under the keys, and at the *north* end of 30 steel magnets, about four inches long, placed close behind the letters painted on the screen The magnets move horizontally on axes, and are poised within a flat ring of copper wire, formed of the ends of the communicating wires. On their north ends they carry small square bits of black paper, which project in front of the screen, and serve as *opercula or covers* to conceal the letters. When any wire is put in communication with the trough at the south end, the galvanic influence is instantly transmitted to the north end; and in accordance with a well-known law discovered by Oersted, the magnet at the end of that wire instantly turns round to the right or left, bearing with it the *operculum* of black paper, and unveiling a letter. When the key A, for instance, is pressed down with the finger at the south end, the wire attached to it is immediately put in communication with the trough; and at the same instant the letter A at the north end is unveiled, by the magnet turning to the right, and with drawing the *operculum.* When the finger is removed from the key, it springs back to its place; the communication with the trough ceases; the magnet resumes its position, and the letter is again covered.

Thus by pressing down with the finger, in succession, the keys corresponding to any word or name, we have the letters forming that word or name exhibited at the other end—the name VICTORIA for instance, which was the maiden effort of the Telegraph on Wednesday evening. In the same way, we may transmit a communication of any length, using an asterisk or cross, to mark the division of one word from another, and the comma, semicolon, or full point, to mark breaks in a sentence, or its close. No proper experiment was made while we were present, to determine the time necessary for this species of communication; but we have reason to believe, that the letters might be exhibited almost as rapidly as a compositor could set them up in types. Even one-half or one-third of this speed, however, would answer perfectly well.

Galvanism, it is well known, requires a complete circuit for its operation. You must not only carry a wire to the place you mean to communicate with, but you must bring it back again to the trough. Aware of this, our first impression was that each letter and mark would require two wires, and the machine in these circumstances having 60 wires instead of 30, its bulk and the complication of its parts would have been much increased. This difficulty has been obviated, however, by a simple and happy contrivance. Instead of the *return* wires extending from the magnet back to the keys, they are cut short at the distance of three inches from the magnet, and all join a transverse copper rod, from which a single wire passes back to the trough, and serves for the whole letters. The Telegraph, in this way, requires only 31 wires We may also mention, that the communication between the keys and the trough is made by a long narrow basin filled with mercury, into which the end of the wire is plunged when the key is pressed down with the finger.

The Telegraph, thus constructed, operates with ease and accuracy, as many gentlemen can witness. The term *model*, which we have employed, is in some respects a misnomer. It is the actual machine, with all its essential parts, and merely circumscribed as to *length* by the necessity of keeping it in a room of limited dimensions. While many are laying claim to the invention, to Mr. Alexander belongs the honour of first following out the principle into all its details, meeting every difficulty, completing a definite plan, and showing it in operation. About twenty gentlemen, including some of the most eminent men of science in Edinburgh, have subscribed a memorial stating their high opinion of the merits of the invention, and expressing their readiness to act as a committee for conducting experiments upon a greater scale, in order fully to test its practicability This ought to be a public concern. A machine which would repeat in Edinburgh words spoken in London, three or four minutes after they were uttered, and continue the communication for any length of time, by night or by day, and with the rapidity which has been described—such a machine reveals a new power, whose stupendous effects upon society no effort of the most vigorous imagination can anticipate.—*Scotsman.*

MISCELLANEA.

Antiquities of the Crimea.—During the last year the workmen employed in making excavations in the environs of Kertch, made some important discoveries Near the village [illegible]limsche two monuments were found, one of which appears to be seven centuries older than the other. The tomb, which is comparatively modern, contained a sarcophagus in marble, which was surrounded by valuable objects. Among them is a sort of altarpiece in marble, of a square form, and ornamented with a beautiful relief, representing a disciple of Bacchus, a silver sceptre, a gilt wooden bobbin-needle, the remains of a bridle, the bit of which is silver, and a woman's mask in gold, of the usual size, which was placed upon the body of the buried person. There were also several vases in bronze, silver, and gold; and to judge by the Greek letters inscribed upon one of the silver vases, it would appear that this sarcophagus was the sepulchre of the wife of a king Reskoreporis Several sovereigns of that name reigned at Panticapée. The other monument, which is of a much more ancient date, contained a sort of brick enclosure, in which was found a vase of clay, containing ashes and burnt bones. The vase is of a very elegant form, and is likely to excite attention from the beautiful drawings upon it. There are—an Amazon on horseback attacking, lance in hand, two warriors on foot, one of which has a helmet, and the other a Phrygian cap. On no other vase previously found in Taurida has there been seen any representation of a similar subject, and this circumstance adds to its value. The horse of the Amazon is white, although the rest of the drawing is red upon a black ground, and this variety of colours is very rare upon Greek vases. The Amazon is not dressed in the costume usually given to female warriors by the artists who lived in the time of Pericles. The style of the drawing altogether gives rise to the supposition, that it dates from the time of Panticapée, that is to say, the fourth or fifth century before Jesus Christ.—*Hague Journal.*

Dr. Clanney's Improved Telegraph —No machine for making signals or numerical symbols can, with propriety, be called a Telegraph, unless it be adapted to express a sufficient number of letters, so as to form words, not only in one, but also in every written language, and by which words and sentences may be formed expeditiously. We have much pleasure in stating to our readers, that Dr. Clanney, of Sunderland, has so improved his Telegraph, that the advantages hinted at above are now completed, and at the trifling expense of fifty shillings for each station, if the station be ten or even twenty miles. This Telegraph is not to be patented.—*Newcastle Journal.*

OFFICE FOR SCIENTIFIC MODELS, PLANS, SECTIONS, &C., LIKELY TO COME BEFORE PARLIAMENT.—There has never yet been a common centre where plans and models might be seen and examined before each is deposited in the Private Bill Office, to be brought formally before Parliament. This has been felt to be a serious inconvenience. Improvements which might be made in the first instance, and alterations to meet the views of the members who take charge of the several matters in the house of the legislature (both of which have afterwards to be effected often at an enormous cost of money and time), have been prevented from the want of a common centre In order to supply this *desideratum*, Mr Northhouse, Parliamentary Agent, at the request of several scientific men, has permitted a room in his offices in Parliament-street to be devoted to the purpose of exhibiting plans, sections, models, &c, connected with public improvements, likely to come before Parliament.

TO CORRESPONDENTS, AND NOTICES.

We have to express our thanks for the numerous Communications which we have received, some of which we are compelled to postpone until our next Number.

To "Fair Play," and the other Brighton Railway correspondents, we beg to inform them, that it is not our wish to act as partisans: the few remarks we made in our last Number, regarding the Brighton Railway, we scarcely thought could be construed into partiality. We cannot comply with "Fair Play's" request, "to give our own views on the subject;" we wish to see the promised Report of the Engineers of the Direct Line, before we give any decided opinion on any of the contending Lines

We shall be happy to hear from our correspondent *———*.

In our next Number will be reviewed—Reply to Contrasts, by an Architect—Hopper *v.* Cust—Sectio-Planography, by P. W. Simms, C.E.—Treatise on the Construction of Oblique Arches, by John Hart Mason.

We have made arrangements for a series of papers on Architectural Criticism, by *Ralph Redivivus.* The first paper will appear in our next Number.

The former Numbers, 1 and 2, may be had separately, or stitched together, forming the First Quarterly Part, price 3*s.*; and the next Number will be published as heretofore.

Received a Medal, in bronze, published by Griffin and Hyams, in commemoration of the Queen's visit to the citizens of London. The likeness is good, but the figures on the obverse are bad; we should like to see them obliterated.

We received as we were going to Press, the "Regulations for Students in Civil Engineering, in the University of Durham, passed by the Senate and Convocation, Nov 22, 1837," which we will notice in our next Number.

PLANS OF THE UNIVERSITY CLUB HOUSE.

X	Lobby and water-closets.			

In a former Journal (No. 2, page 15) we gave a drawing of the elevation, and description of the exterior; we now, agreeable to our promise, give the plans of the two principal floors, which are drawn to one half the scale of the elevation.

The hall A is entered through a Corinthian portico of four columns and a small lobby (with Spanish mahogany doors); it is lofty, but rather limited on plan. The principal floor is approached by a wide flight of stone steps, through mahogany folding doors, and on each side are square detached antæ, which, with the walls, are painted and shaded in imitation of stone. On the right is the spacious coffee-room, on each side are two square antæ of scagliola, in imitation of red granite, with enriched bronzed caps, and statuary marble bases, supporting enriched consoles and entablature or cornice, which returns round and divides the ceiling into three large compartments, the middle one being largest; in the centre of each is a very chaste water-leaf flower, of *papier maché*, concealing a ventilator, and surrounded by an enriched rim and honeysuckle border. The walls are divided into panels by an enriched moulding, over a moulded dado. The two chimney-pieces are of black and gold marble, with square panelled antæ, placed on the angle, with entablatures. The wood finishings are grained wainscot, and the walls tinted. The committee-room E is finished somewhat similar to the coffee-room. The waiters' room K is fitted up with hot and other closets, with a shaft communicating with the basement, with apparatus for raising and lowering the dishes, &c. Adjoining is the house dining-room, approached from the grand staircase by a lofty corridor F, which also leads to the secretary's M and clerk's room N, the water-closets G, and back staircase L.

The grand staircase E is ascended by two wide flights of steps, with rail or capping, and turned ballusters, all of stone. The ceiling is divided into compartments, and ornamented with enriched mouldings and pateræ. The walls are painted in imitation of granite.

The evening or drawing-room R is divided into two compartments by Sienna scagliola antæ, with marbled caps and bases, supporting an enriched entablature. The ceiling is divided into panels by a guilloche ornament, the centre of each having a coffer and flower, and the walls are divided into large panels by an enriched moulding. There are two chimney-pieces of statuary marble, having square antæ, with enriched caps, over which are carved the arms of the two Universities. At the east end is a frontispiece, with architrave and consoles for a large plate of silvered glass. The wood-work is excellently painted, in imitation of Russian birch. Communicating with the evening-room is the writing-room and library; the latter contains three ranges of bookcases, occupying the whole of the three sides of the room, the centres having pediments, supported by pilasters; over the two Sienna marble chimney-pieces are large looking-glasses. The door of the writing-room and the bookcases are made of beautiful Russian birch, and the other fittings painted in imitation.

The ceilings of these two rooms are coved, and have an enriched frame and cornice, and a handsome flower in the centre; the walls of the writing-room are panelled.

The windows of the corridor S are of glass, frosted by flouric acid, having a chaste lotus border, and the arms of the two Universities left transparent. At the back is a committee-room, with waiters' room adjoining. On the upper floor there are two billiard-rooms, smoking room, three rooms fitted up with copper-lined baths (supplied with hot and cold water), servants' dormitories, &c. The domestic offices are admirably arranged in the basement and mezzanine stories. The kitchen is 28 feet long and 22 feet wide, with large recesses, containing

an oven, stewing-stoves, &c., which are ventilated above by louvre boards. The range is 6 feet 6 inches long, and has a boiler at the back, containing 100 gallons of water, from which the baths, &c., are supplied. The hot closet is heated by steam from a large boiler behind. A massive elm table, 12 feet by 4 feet 6 inches, and 5 inches thick, with a hot plate in the middle, 6 feet by 1 foot 6 inches (also heated by steam), stands in the centre.

The scullery and housemaids' rooms contain lead-lined troughs, each supplied by hot and cold water (heated in a boiler placed at the back of the stove in the servants' hall). On the mezzanine story are dressing-rooms, butler's pantry, buttery, dispense for wine, steward's, store, housekeeper's, and still rooms; also several marble stands, supplied with hot and cold water for washing.

The ventilation of the large rooms is effected by means of hopper-heads placed over each of the perforated flowers in the ceilings, and conveyed by zinc trunks, 8 feet by 8 inches, through the floors, to flues built in the walls between the smoke flues, by which arrangement the air becomes rarefied and immediately ascends.

The supply of water, for which there are various tanks and cisterns, will be between 4 and 5,000 gallons.

The several works are generally well executed; the rooms are capacious and well arranged; and the whole has more the appearance of convenience than splendour.

ASPHALTIC MASTIC, OR CEMENT OF SEYSSEL.

In the list of Patents in our last Number, will be found one that was granted to "Richard Tappin Claridge, of Salisbury Street, Strand, for a Mastic Cement or Composition, applicable to Paving and Road-making, covering Buildings, and the various purposes to which Cement, Mastic, Lead, Zinc, or Composition are employed." We have, through the kindness of Mr. F. W. Simms, been able to obtain the following particulars:—He was engaged professionally to visit Paris, in October last, to examine the Mastic, try experiments, see the various purposes it had been applied to in Paris, and to report whether it was suitable for the same purposes in this country. After having made a rigid inquiry, and seen several Engineering and Architectural works, where it had been applied, and obtained certificates from several of the most eminent Engineers and Architects in Paris, who highly approved of it, he did not hesitate to recommend its introduction into this country.

In various parts of the eastern chain of the Jura mountains, there are bituminous veins of greater or less extent, but the only place at present known where the asphaltic rock is to be found is at Pyrimont, in the Department de l'Ain. In this immediate vicinity is also obtained a peculiar kind of mineral pitch, there called bitumen, which, upon being mixed in certain proportions with the asphalte, forms the mastic or cement, which in France, after years of struggling with prejudices, and the opposition of parties interested in its failure, is obtaining so large a share of patronage, as to be extensively employed both in the public and private works of that kingdom.

For many years after the discovery of the valuable properties of the asphalte, the mine at Pyrimont was the property of a company of Swiss merchants; but, from their defects of management, and from the limited extent of their finances, their operations were confined within very narrow bounds, and at length languishing, the properties of the mastic was likely to have become lost to society.

The business has now fallen into the hands of a private company at Paris, who, with a capital of thirty thousand pounds, purchased the mine at Pyrimont, and are carrying on an extensive trade in its manufacture.

The asphaltic mastic of Seyssel, when prepared for use, is a compound of two mineral substances, one is the native asphalte, the other is bitumen; the proportion of the former in the amalgam is ninety-three centimes, and of the latter seven centimes. The asphalte is extracted from the mine in blocks, and reduced to an almost impalpable powder before it is mixed with the bitumen. The latter, as extracted from the mine, is first broken into pieces of about the size of an egg, these are put into boiling water, and the particles which rise to the surface are purified by boiling for twenty-four hours; the result is, the bitumen to be mixed with the pulverized asphalte. The combination of these two substances form the mastic or cement, which being reduced to a fluid state by the application of caloric, is poured into moulds of any shape required; or in this state used as cement in hydraulic works, &c. The use of the bitumen appears to be the giving of ductility to the mastic; and if a very minute quantity of sulphur be added, the mastic will become hard and partially brittle.

The genuine mastic possesses the hardness of stone, and yet preserves a certain elasticity. When used as pavement for terraces or footpaths, it appears to resist the wear equally well with granite, and when prepared in the manner now adopted in Paris, it is difficult to distinguish it in such situations from that stone. One of the finest specimens of paving, and which at first sight has the appearance of granite, is that on the north side of the palace and gardens of the Tuilleries; it is about eleven hundred yards in length, and ten feet wide; it is composed of the asphaltic mastic, and the joints which traversely cross it the whole breadth, and which at present appear to divide the pavement into a number of large equally-sized slabs, are disappearing by the mastic becoming more dense from the tramping of feet, so that this extensive piece of pavement will soon appear from end to end, like one immense sheet of stone.

A few minutes after the mastic has been spread in a fluid state, it again takes its natural density, which is such, that at the heat of 30° Reaumer (equal to 100° of Fahrenheit), it resists all impressions from an ordinary force. Its extensive application to the *covering of buildings instead of tiles, slate, or lead* have induced the trial of experiments in France, by which it was ascertained that it is anti-electric, a property which it is desirable that all bodies should possess that are employed in roofing. Its application also for the flooring of halls, passages, and apartments, is in no way dangerous on account of fire, as it is not inflammable, the quantity of pitch which it contains being so very small. For the floors of underground kitchens, &c., it is particularly applicable, it being warm, and keeps out all damp, as well as vermin and insects which are frequently so abundant in such places. When employed in the construction of water-tanks or reservoirs, it imparts neither taste, smell, nor colour to the water it contains.

The following are the retail prices of this material, both in its native and manufactured states, as charged by the company in Paris:—

	£	s.	d.
Asphalte in its native state, per 100 killograms (220 pounds English)	1	0	10
Foot pavements, &c. &c. per metre superficial (1,196 square yards English)	0	5	10
Covering of roofs, per metre superficial	0	7	6

Which gives for foot-pavements ABOUT $6\frac{1}{4}d.$ per square foot, and for roof $8\frac{1}{4}d.$ per square foot.

Preparations are now making for applying the asphaltic mastic of Seyssel on a part of the Greenwich Railway, with a view to preserve the arches of that extensive viaduct free from damp. Also as foot-pavement in several of the metropolitan parishes; and in one of the principal streets of Liverpool, &c. The British public will therefore soon have an opportunity of judging for themselves, of the utility of a material which is held in such high estimation by their continental neighbours.

The introduction of this substance into this country is due to R. T. Claridge, Esq., a gentleman who has spent much time on the Continent, and who has obtained from the company at Paris a contract, whereby they agree to supply this country with the produce of their mine at Pyrimont, through *him only*.

We shall conclude our subject with extracts from the "*Bulletin de la Société Géologique de France*," vol. viii. p. 138. *Communicated by* M. ROZET, *March 7th*, 1836.

"The mastic of asphalte is employed for covering terraces, roofs of buildings, footpaths of bridges and streets, arches, cellars, and interior areas, &c. Also in the construction of aqueducts, basins, and of all kind of hydraulic works. It has been used to cement stones, bricks, and even metals.

"Many works have been executed in Paris and its environs with the mastic of Seyssel; for instance, the footpath on the Pont Royal, and that of the Louvre; trials which have so well succeeded, that the authorities of the city have decided to adopt the same material for the footpaths of the streets, also of the Place de la Concorde, (formerly called Place Louis XV.) which is about to be laid out on an extensive and grand scale. . .

"The magazine of provision at Bercy has been covered for upwards of a year with this mastic, and succeeds perfectly.

"In the years 1832, 33, 34, this mastic was with equal success employed in the construction of the military works at Vincennes.

"It has also been successfully employed in the military constructions at Douai, Besançon, Bourbonne-les-Bains, Grenoble, and Lyons. In the last city, all the covering of roofs and the interior areas of the new forts have been constructed with it. . .

"More than forty years ago, at Fort l'Ecluse, a small building was covered with this mastic, which has ever since continued in a perfect state of repair.

"The asphaltic mastic, the nature of which now begins to be generally understood, will render peculiar advantages in architectural constructions."

REVIEWS.

WELBY PUGIN AND HIS CRITICS.

A Reply to Observations which appeared in Fraser's Magazine, for March, 1837, *on a Work entitled "Contrasts."* By the Author of that Publication. London, 1837.

Reply to "Contrasts," by A. Welby Pugin. By an Architect. London, 1837.

An Apology for a Work entitled "Contrasts," being a Defence of the Assertions advanced in that Publication, against the various Attacks lately made upon it. By A. WELBY PUGIN. Birmingham, 1837.

IN evil hour for himself, and with ill-advised pen, did Mr. Welby Pugin betake himself to the task of writing his "Contrasts;" though, if, as we cannot help suspecting, he was prompted to it by the desire of distinguishing himself, it has certainly answered his views, by having secured for him a marked degree of notoriety. Those who know any thing whatever of that work, require not to be told that it manifests excessive bitterness, both towards his brother Architects, and the Protestant Church; and that so far from partaking of the *suaviter in modo*, the offensiveness of the remarks themselves is greatly increased by that of the imperious tone he assumes, on the one hand, and the sneering, not to say coarse and burlesque satire, in which he indulges on the other, and not least of all, in his frontispieces and other illustrations. We give him all due credit, however, for boldness and fearlessly speaking out his sentiments, notwithstanding that they are the very reverse of flattering, nay, absolutely unpalatable to that class of persons who would be purchasers and readers of his book. Instead of appealing to their prejudices, their sympathies, or their interests—in-

stead of cajoling them by any of that nauseating palaver which can be gulped down only along with the wine at a public dinner, he rails at them in good set terms.

Such being the case, he ought to have made up his mind beforehand to endure with resignation, with valorous patience, all the buffeting he would meet with in return. If we may believe him, he was well aware that he was engaging in a very perilous enterprise; for he says in his "Apology"—"When I determined on publishing my work of 'Contrasts,' I was fully prepared for all the censure that has been, or may be passed upon me, for venturing on so bold an attempt." Yet no sooner was the work reviewed at length—which was not until nearly a twelvemonth after its first appearance, for at first it seems to have been sent to Coventry by the critics—than he began to cry out lustily, and to show himself the most sensitive and thin-skinned of mortals. Instead of feeling grateful towards the writer in "Fraser's Magazine"—though perhaps he really did feel so at heart—for pushing him conspicuously into notice, by giving him and his book a place in the "Batch of Architects," he pretended to be aggrieved, and published a querulous reply, asserting that his work had been "reviewed in a manner calculated to be extremely injurious to his reputation."

Poor man! Greatly injured Welby! Certainly it is exceedingly hard, that after traducing the whole of the profession generally, and many of the chief members in it by name, holding up their works to scorn and derision, and endeavouring to make it appear that architecture has been uniformly retrograding among us, and that it is now almost at its very lowest ebb—it is exceedingly hard, we repeat, that after "reviewing" the productions of so many living architects, "in a manner calculated to be extremely injurious to their reputation," you yourself should be treated with equal freedom. The fortitude with which he had armed himself at the outset, must surely have all oozed away, when he exhibited so much wincing as soon as he felt the lash. It having been intimated to him, it seems, that a reply would most probably draw down upon him a more severe castigation than that he had received in the "Batch"—of which it may be said *castigat ridendo*—he assures the critic, at least the publisher, that "he is greatly deceived if he imagines he is to be bullied or terrified into silence." Now, as to *bullying*, most people will think the author of the "Contrasts" might as well have avoided an expression that others will be apt to apply to himself; for

"*Quis tulerit Gracchos de seditione querentes?*"

Surely nearly all who have read that work will allow, that it contains no little brow-beating and bullying; and that, as if there were to be no appeal from Mr. Pugin's *infallibility*, he boldly passes summary damnation on every modern building, and every modern architect mentioned in it. "Of fierce denunciation," says the writer in Fraser, "there is enough, and more than enough. In the most sweeping and unqualified manner, he, in one brief sentence, gives up to reprobation Buckingham Palace, the National Gallery, the Board of Trade, and the new buildings at the British Museum, declaring that 'no one can look at them, or any of the principal buildings lately erected, but must feel the very existence of such public monuments a national disgrace.' This is not criticism, but the mere strut and swagger of what would fain pass for it."—Most certainly, and as a professional man, it was in some degree incumbent upon Mr. Pugin to adduce some reasons that would have justified his severity; the more so, because, if deserved, it might then have operated as a wholesome caution in future; nor can it be urged by him that such explanation was unnecessary for architectural readers, since, if we are to believe him, all the architects of the present day are ignorant of what constitutes good taste. Even though he omitted criticism in the first instance, he might have supplied the deficiency afterwards in his "Reply" to Fraser; yet, instead of availing himself of the opportunity so offered, he evades it by merely saying, "as touching the New Palace, National Gallery, &c., I am sure that enough detailed criticism had been written on them previous to the publication of my work." We very much question this: however, supposing it really to have been the case, Mr. Pugin might as well have given us satisfactory assurance of it, by referring to the publications where it is to be found, which he now leaves us room to suspect it would puzzle him to do; at least we have not been so fortunate as to meet with any of the *detailed criticisms* he alludes to, except in regard to the first-mentioned building, in the series entitled "Strictures on Structures," which appeared in the "Printing Machine."

That he neither understands nor relishes banter when directed against himself, is evident from the very grave apology he makes for having "let slip the opportunity of introducing St. Marie's Grange, which we understood was designed by himself, by way of contrast to some one of 'the miserable edifices of the present day.' Few will attribute the omission to excess of modesty." His answer is—"In regard to the omission of my own house among the "CONTRASTS," which my reviewer says cannot be attributed to excess of modesty, I beg to say, I am by no means possessed of so large a stock of impudence as he supposes; at any rate, I have too much common sense and feeling of propriety, to exhibit, as an example, a small dwelling, erected with limited means, and simply calculated for a retired residence." Really, after displaying so much of what most persons will consider anything but a feeling of propriety, he shows himself all of a sudden to be strangely scrupulous and delicate. In fact, notwithstanding the reasons he assigns, we cannot help setting down this qualmish feeling of propriety, to the consciousness, that judged by the standard by which he himself has measured the productions of others, his own design would be found remarkably deficient. It is but a lame shuffling excuse, to tell us that his house is "a small dwelling, erected with limited means," because several of the buildings he so severely reprobates, have, in regard to their size, been equally limited as to the funds allowed for them; while, let his residence be ever so small, that circumstance certainly did not hinder him from exhibiting superior taste in it, both in regard to its general style and details, so as to prove by example how much may be made of the most unpromising and limited subject in the hands of a true artist. It is downright shuffling equivocation to allege its size as an apology, because, were it no larger than a cottage or lodge, there might still be considerable effect in it as a design, picturesque outline, tasteful combination of features, and pleasing elegance of forms, if no very great degree of enrichment. At all events, we ourselves have seen things of the kind that have satisfied us far better than what has been upon a much larger scale. There was, besides, one thing greatly in Mr. Pugin's favour, namely, his being his own architect, consequently quite free from all control and interference, and at liberty to act entirely according to his own judgment; which was an advantage not possessed by every one of those whom he so severely takes to task for not having done better. We have therefore our misgivings, and cannot help fancying, that if *weighed in the balance* (*vide* his tail-piece to the "CONTRASTS"), St. Marie's Grange would not be found better than some of the things he has decried. We certainly should like to be better acquainted with this same St. Marie's, respecting which some one has observed, in a manuscript piece, now lying before us,

> "What St. Mary your Marie may be, I know not; yet from your attacks
> Upon the profession, conclude she's no other than St. Mary *Axe*;
> Since chop us, and hew us you do, and preach to us in strain so objurgatory,
> That you'd lead us to Paradise p'rhaps, but first put us all into purgatory!"

Of a truth he is objurgatory enough, and not least of all towards Protestantism, the spirit of which he represents to be utterly inimical to art, and tending to depress all its energies. Whether in his animadversions upon it he speaks without a prompter, or is merely the mouthpiece of some one behind the curtain, we pretend not to judge, and therefore keep our conjectures to ourselves. Yet let his arguments in favour of Popery be his own or not, we think them highly indiscreet in a religious point of view. No one denies that Popery is a splendid form of religion; that many of its ceremonies are gorgeous and impressive, and that it has enlisted the fine arts in its service for the purpose of alluring the multitude, and of securing their allegiance by an imposing display of pomp and authority, and converting devotion into pageantry and *spectacle*. Yet, if we look at all further than mere outward appearances, we shall discover, that in all this there is as much, if not more, of superstition than of piety, on the part of the people; as much zeal for the maintenance of their own authority, as for the honour of God, on that of the priests. We might say, it is not so much the Almighty himself, as the saints, their shrines and relics, which are the objects of Roman Catholic worship, and which have power ascribed to them almost paramount to any other. We desist, however, from touching further upon this head, as being one not exactly suited to the character of our Journal, and shall therefore merely remark, that when Mr. Pugin thinks to plead the cause of the Romish Church, by laying so much stress upon the encouragement it affords to art, he does not show himself a very judicious advocate. Nay, supposing him to be in good earnest, he leaves it to be inferred, that he is ready in all consistency to allow the religions of ancient Egypt and Greece to have been—so far at least—preferable to the Christianity of the Protestant Church; for they likewise were the promoters of architecture and the other arts, in an equal, if not still greater degree than even Popery. So that we are at liberty to imagine, that had the author of the "Contrasts" lived in the times of the first Christians, he would have inveighed against them as barbarous, tasteless iconoclasts, "canting fanatics," and would have moaned over "ruined walls, desecrated shrines, and mutilated images," fallen a prey to the rage of religious innovation. Of consistency, however, he is altogether regardless, otherwise he would not, as he now does, have made his brother architects of the present day chargeable with the deficiencies which, in the same breath, he labours to prove arise out of Protestantism, and are inseparable from it. To one of the two, therefore, he is obviously unjust; and if the truth is, that our national church is peculiarly unfavourable to architecture, the wonder becomes not that our archi-

tects should do no better, but that they actually do as well. It is strange, too, that one who takes so much credit to himself for his candour, should have brought forward any instances at all of church architecture as fair specimens of the state of the art among us at the present day, it being that very branch of it which is least successfully cultivated. Still we need not be very surprised at his doing so, when we find him, with equal fairness and impartiality, culling out St. Pancras Chapel, and some others, as average specimens of the architectural taste of the day.

On the other hand, we will not be quite sure that Popery itself has not much to answer for on the score of corrupting and debasing art, and forcing it into a wrong direction. No doubt it has furnished employment to thousands of artists; but of what kind? Are not its churches like so many manufactories of saints and mothers of God, painted to order? or else lined with horrible representations of martyrdoms, not to mention many subjects, which, if not quite so disgusting, are still more scandalous? And what, we ask, has it done for architecture in any but the Gothic style? In all that regards taste, St. Peter's is the costliest piece of ugliness;—as a work of art, immeasurably inferior to the Pantheon; so that if architecture has anything to do with religion, we must award the palm to the paganism of ancient Rome. And here we may quote, in corroboration of our opinion, what is observed by the "Architect," in his "Reply."

"Where, then, were those glorious sentiments so peculiar, we are told, to the Romish faith, when the buildings of Italy were plastered up and Romanized; when all kinds of mongrel additions were made to the finest and purest of their churches; when, in short, the Gothic cathedral was transformed and degraded into the pseudo-classical hall? There is an utter absence of all sentiment in the frightful additions which the classic architects intruded on the buildings of Italy. England never dreamed of recasing her churches in Roman habits, as in *orthodox* Italy, for an example of which take the church of the Lateran; and any such monstrous absurdity as that with which Jones is chargeable, of tacking a Roman portico to a Gothic cathedral, was no doubt justified in his mind by some such tasteless precedent."

By way of answer to this, Mr. Pugin tells us, that "there was not sufficient zeal existing in this country, after the change of religion, to recase many religious edifices;" and assures us, that the *reformed* clergy had no very great veneration for their cathedrals. That may be; yet wherefore are the Protestants of the present day to be held answerable for the ruthless spoliation of ecclesiastical edifices, committed by their ancestors? It cannot be urged that they are at all insensible to the beauties of the Gothic style, that *very style* whose neglect Mr. Pugin chiefly deplores, since both Protestant England and Germany have done infinitely more for the study of it in our own days, than the whole of Catholic Europe. It is true, we can no longer cultivate the style itself for ecclesiastical purposes, upon the scale and with all the pomp of accessory enrichment required by the Popish service. Consequently, if we err it is in retaining as a model what we must necessarily fall short of, and would therefore, perhaps do better to abandon altogether. Granting Mr. Pugin to be indisputably right in all he asserts, he only convinces us, that if the advancement of the arts among us depends upon Popery, as a *sine qua non* condition, we must leave them to their fate, it being quite useless and labouring against the stream to promote them; because, even should he make proselytes among architects and other artists, and bribe them over to the church of Rome, by the promise of inspiration and genius as the reward of their conversion, that would avail nothing. Rather would it throw all employment in the way of church-building into the hands of those blockheads, as we must suppose them, who still adhered to such a beggarly form of religion as that of Protestantism. Or does he hope to gain over to his cause the whole body of the people of England? Hardly can we imagine *him* to be blockhead enough for that, since it would be attributing to them the utmost enthusiasm for art; whereas, he contends, and the main object of his book is to show, that they have not the slightest feeling for it whatever. The Turks say, that the world rests upon the back of an elephant, but upon what the elephant rests they do not inform us; and it is somewhat after this fashion Mr. Pugin would have our zeal for art lead us to Popery, without telling us where we are at first to get a sufficient stock of it to carry us thither. From our Protestantism it certainly cannot be, since, according to his own showing, that operates upon art nearly as an extinguisher does upon a candle. Altogether it is a most hopeless and helpless affair—so much so, that it is strange Mr. Pugin himself should not have perceived that he had undertaken as fruitless a task, as that of attempting to wash a blackamoor white. In an article in our very first Number we alluded to the one-sided and disingenuous mode adopted by Mr. Pugin, in his "Contrasts," for the express purpose of making it appear—to those at least who trust solely to his representations—that not a single production of modern times will bear the slightest comparison with anything erected in this country previous to the Reformation; since which fatal epoch we have, it would seem, gradually been getting worse and worse. Respecting this kind of candour, the "Architect," too, gives him a rub in the following passage:—

"While he claims to have conducted the comparison with *the greatest candour*, there are many examples chosen of modern works, for which, in fair dealing, others should be substituted. And, first, the church of St. Mary's Redcliffe, Bristol, is contrasted with that of All Souls, Langham Place. Now, really, if he is in want of something very droll and striking, he might instance the church of St. Paul, in the same city; but if anxious only to do justice alike to present or past times, he ought rather to bring forward some such structure as St. Dunstan's in the West—a very fair sample, indeed, of the many churches now building, and whose beautiful interior is well worthy of his inspection. In the same unamiable mood, he contrasts St. Pancras Chapel, London, with Bishop Skirlaw's Chapel, Yorkshire. Now, without leaving the county, we can refer him to one lately built and endowed, at private cost, at Oulton, near Leeds, with every suitable enrichment of stained glass, without any regard to expense—an instance of Protestant devotion by no means of rare occurrence. Equally uncandid is any comparison between Ely House, Dover Street, and Ely Place, Holborn, as examples of the episcopal residences of the nineteenth and sixteenth centuries. In proof of it, we briefly refer him to the restoration which has been effected by the Bishop of Carlisle on Rose Castle, Cumberland; and the additions, though certainly inferior to the former, which have been made by the Archbishop of Canterbury at Lambeth."

No, Welby Pugin is not the man to point to anything that would redound to the credit of any living architect: his patriotism and love of art are made of such strange stuff as to lead him a-hunting in holes and corners after such choice samples as St. Pancras Chapel, while they blindfold his eyes to such buildings as St. Dunstan's in the West, the Hall of Christ Church Hospital, and very many others, both in the metropolis and out of it; for though he published his last pamphlet at Birmingham, he does not seem to have discovered the new Free Grammar School there. So fantastic is the monomania by which he is afflicted, that, unless it disturbs his judgment, merely in regard to architecture, he doubtless insists that a handful of chaff is, to all intents and purposes, a good sample of the wheat—that their shells will serve as well as their kernels to enable us to judge of nuts—and that the quality of wine may be tested from tasting stale bottle drainings! Nevertheless, Mr. Pugin's mode of proceeding is remarkably convenient; and we do not know—we feel half-tempted to adopt it ourselves, and get up a volume of "Contrasts," for the purpose of exhibiting the odd whims, freaks, fancies, and funninesses of Popish architecture, as exemplified in the works of Borromini, and many others, whose genius has been fostered under the all-inspiring influence of the Romish Church. Neither should we despair of being able to show very convincingly, that, miserable and bungling as may be some specimens of pseudo-Gothic produced of late years, there are many buildings—and those not the very best of all which might be selected—that seem nearly perfection when compared with Dance's Gothic at Guildhall. Whether it be because Protestantism has been on the wane in this country since those restorations were made, we pretend not to decide.

But how does Pope Pugin parry the thrust made at him by the Protestant "Architect?" Why, he either overlooked the passage we have quoted altogether, or else entirely forgotten it afterwards; although, as he thought fit to answer his pamphlet at all, he ought on no account to have passed unnoticed what is there said, because it amounts to a charge of blinking stupidity on his part, if not of downright dishonesty. Perhaps he comforts himself by thinking, that, at the worst, he can only be reproached with having acted jesuitically, and that the most unfair treatment is quite good enough for heretics.

It is now time for us to desist; yet we cannot prevail upon ourselves to lay down our pen before informing our readers, that to the "Apology" are appended "Some Observations on the State of the Arts in England; showing that the degraded condition into which art has fallen is owing to the absence of Catholic feeling among its professors the loss of all ecclesiastical patronage, owing to a Protestant church establishment, and the apathy with which a Protestant nation treats the higher branches of Art." It is a pity Mr. Pugin could not show that Protestantism laid an embargo on the Elgin Marbles, and prevented their being imported into this country; and that it smothered every spark of feeling and genius in John Flaxman, many of whose monumental subjects are fraught with such holy energy of conception and sentiment, that, in comparison with them, most things of the same class, by Catholic artists, are little better than theatrical parodies—sometimes profane buffooneries; and surely Mr. Pugin must be antiquarian enough to know, that many of the ornamental carvings in vogue in churches, during the "good old Catholic times," did not bespeak much devotional feeling, being anything but of an edifying nature.

If we may believe the author of "Contrasts," every branch of art is at this moment at the lowest stage of degradation in this country; and, although expressly not named by him, yet, as he makes no direct excep-

tion in their favour, we must suppose he is not inclined to admit any in regard to architectural drawing and engraving. Here, at least, we should have thought he would have found much to approve—to admire—even to extol: but no; the finished truth and exactness, or poetic feeling, given to their subjects by such artists as Mackenzie, Wild, Neale, Cattermole, Roberts, Lewis, and many others, must yield to the loose and incorrect, and equally harsh, delineations of Hollar, whom, we presume, Mr. Pugin has proposed to himself as his model in his rude and almost shapeless scratchings, of which the above-quoted MS. says—

"Your etchings are not quite divine, 'cause, in truth, there's not one in the batch
That does not, for all the world, look as if etched by the hand of *Old Scratch!*"

As for the Annuals, in regard to them he is severe even to bitterness; and here, again, he does not except the "Landscape Annual," whose beautiful architectural subjects might, we think, have mollified and propitiated him. He denounces the Annuals, one and all, as an "everlasting disgrace to the era in which they were manufactured;" and "Books of Beauty, Flowers of Loveliness, Gems of Beauty," &c., as "*absolute trash.*" Really, this is quite awful. When, however, he charges our artists with offending by impure and wanton subjects, in which hardly common decency is observed, his laudable indignation quite overlooks the transgressions of those Catholic painters, Correggio and Titian, whose Ledas, Danaes, and Venuses, certainly come under the description of "women thrown into lascivious positions." Again, we repeat, Mr. Welby Pugin is the most indiscreet advocate we have met with; we suspect that he has never read Salvator Rosa's bitter remarks on the profane subjects tolerated in Catholic churches. Ere long, Mr. Pugin will, perhaps, afford us an opportunity of returning to him again; nay, it is possible that what we have said may be the occasion of his favouring the world with another pamphlet, in which he will hardly fail to call to his assistance the article which appeared in the last number of the "Dublin Review," containing the following more naive than respectful observation: "The 'CONTRASTS' is a book full of life and spirit, and *amusing, though unto sadness*"!!! Truly, a most sad compliment; yet we will not be certain that the last word is not a misprint, and that *madness* was not the word intended; for that there is no little portion of madness in the book is quite indisputable.

Memerials of Cambridge.—No. 2.

[SECOND NOTICE.]

IN our first notice of this work, we spoke of it only in general terms, and chiefly for the purpose of suggesting improvements, that if adopted would give it a decided advantage over the 'Oxford,' without at all interfering with uniformity of plan in the two series. We must now say that we are threatened with a want of uniformity between the two of a totally different nature; for while the same plan is adhered to without any of those changes in it for the better, of which it is susceptible, the execution, we have great reason to fear, will be sadly inferior. Our apprehensions that such will turn out to be the case, are tolerably well justified, by the 'View of Trinity College, from the S.E. angle of the Cloisters,' in this second number; where an architectural subject, by no means the best in itself, is made to appear to the utmost disadvantage, not only by utter want of taste in the mode of showing it, but also by bad drawing, and equally bad engraving. In the drawing, to tameness and want of spirit, are added such indistinctness and incorrectness, that the draughtsman appears to have *fumbled* his way without understanding the architectural forms and character. Indeed, the most prominent objects in the 'View,' are the three gawky gownsmen at the corner of the cloister, who have only two pair of legs and a half among them. What one of them has done with one of his legs, we know not; perhaps he has put it into his pocket; or a still better *perhaps* is, that he has sent it to look after Mr. Le Keux's right-hand, which the latter certainly parted with, when he parted with Mr. Mackenzie. Nay, as for the matter of that, he seems to have parted with the other also, and not to have a hand left. At all events we must suppose that he engraved this plate by proxy, without ever once touching it; a supposition the reverse of uncharitable, since we should otherwise be compelled to say that he cannot now even remind us of what he once was.

To be really kind to Mr. Le Keux, we must be seemingly cruel, and plainly tell him, that when he suffers his name to be affixed to such a miserable production as this print, he is guilty of a double injustice; in the first place towards the public, in the second towards himself and his own reputation. As affects either, it surely is not very fair to palm off, by means of the credit hitherto deservedly attached to Mr. Le Keux's name, what in itself is absolutely disgraceful, and fit only to pass muster in a girl's scrap-book. Let Mr. Le Keux then take our admonition seriously to heart, and beware in good time. There may be limit even to the gullibility of the public, and unless he would open their eyes to the system he is now pursuing, he would act prudently in cancelling the wretched engraving alluded to, not only as discreditable, but as likely to prove highly injurious to the success of the work as a speculation.

A Practical Treatise on Warming Buildings by Hot Water, and an Inquiry into the Laws of Radiant and Conducted Heat; to which are added, Remarks on Ventilation. By CHARLES HOOD, F.R.A.S *Illustrated by numerous Wood-cuts.* London: WHITTAKER & Co. 1837.

THE Author commences his work with a judicious and instructive inquiry into the causes of circulation of water and its consequences; he points out the obstacles which frequently occur either through accident or inefficient apparatus; he then describes the laws which regulate the circulation of hot water, the effect of friction occasioned by water passing through small pipes, the comparative advantages of warming by steam and hot water, the rates of cooling, description of different boilers in use, their advantages and defects, and the relative proportion of the boiler to the pipes, wherein he observes,

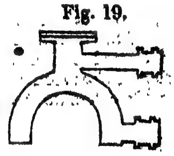
"It is obvious that the extent of surface which a boiler ought to expose to the fire, should be proportional to the quantity of pipe that is required to be heated by it; and it is not difficult to estimate these relative proportions with sufficient accuracy, notwithstanding the various circumstances which modify the effect. Reckoning the surface which a steam boiler exposes to the fire, at 4 square feet, for each cubic foot of water evaporated per hour;* and calculating the latent heat of steam at 1000°; we shall find that the same extent of boiler surface, which would evaporate a cubic foot of water, of the temperature of 52°, into steam, of which the tension is equal to one atmosphere, would supply the requisite heat to 232 feet of pipe, 4 inches diameter, when its temperature is to be kept at 140° above that of the surrounding air. The following proportions for the surface which a boiler for a hot-water apparatus ought to expose to the fire, will be found useful.

Surface of Boiler exposed to the Fire.	4 In. Pipe.	3 In. Pipe.	2 In. Pipe.
$3\frac{1}{2}$ square feet, will heat	200 feet, or	266 feet, or	400 feet.
$5\frac{1}{2}$	300	400	600
7	400	533	800
$8\frac{1}{2}$	500	666	1000
12	700	933	1400
17	1000	1333	2000

"In order to estimate the quantity of surface, which is acted upon by the fire, an allowance must be made for the flues which circulate round the exterior of the boiler. Thus, suppose the boiler, fig. 15, to be 30 inches long, there will be about $8\frac{3}{4}$ square feet of surface exposed to the direct action of the fire; and suppose, also, there are four external flues, one on each side, and two on the top of the boiler, each being 12 inches wide; we may reckon that one-half the effect is produced by these flues, which would have obtained, had the direct action of the fire been employed on the like extent of surface; therefore the flues will be equal to 5 square feet of surface exposed to the *direct* action of the fire, making altogether $13\frac{3}{4}$ square feet as the available heating surface of a boiler of this shape and size. This would be sufficient to heat about 800 feet of pipe 4 inches diameter, when the excess of its temperature above that of the surrounding air is 140°, as before stated. A boiler of the same shape, and 24 inches long, has about 11 square feet of surface, when calculated by the preceding rule; a boiler 36 inches long, has $16\frac{1}{2}$ square feet of surface; and a boiler 42 inches long, has 19 square feet of surface; the increase being directly proportional, in the simple ratio, to the length.

Fig. 15.

Fig. 19.



"A circular boiler 30 inches diameter, like the fig. 19, with a 9-inch circular flue round the outside, will expose, as nearly as possible, the same extent of surface as a boiler 30 inches long of the shape last described, and therefore the one will be as effective as the other. The surface of other sizes of this shaped boiler can be easily calculated; but instead of varying in the simple ratio of the length or diameter, it will be found to be proportional to the *square of the diameter*, so that the proportion of surface increases more rapidly than in the arched boiler. Thus a circular boiler 24 inches diameter, has $8\frac{3}{4}$ square feet of surface exposed to the fire; a 30-inch has $13\frac{3}{4}$ square feet; a 36-inch, $19\frac{3}{4}$ square feet; and a 42-inch, $26\frac{3}{4}$ square feet; the small sizes having less surface, and the large sizes having more, than the arched boilers of the shape of fig. 15."

The Author then proceeds to describe the construction and dimensions of furnaces, and their proportions to the boiler and quantity of pipe to be heated. He next explains the theory and laws of heat which bring us to the experiments made by the author on cooling. Here we must remark, that these experiments are made on such a small scale as to render them very unsatisfactory for any practical purposes, as in the following case:—

* The surface of a steam boiler which it is necessary to expose to the action of the fire, in order to evaporate one cubic foot of water per hour, varies from 2 to 10 square feet, according to the rapidity of the draught, and the intensity of the heat of the furnace. When the very small surfaces are used, mechanical means are requisite for blowing the fire.

"To ascertain by experiment the velocity of cooling, for a surface of cast-iron, I used a pipe 30 inches long, $2\frac{1}{4}$ inches diameter internally, and 3 inches diameter externally: the ends were closed, and the bulb of a thermometer was inserted about 3 inches into the water at one end, the temperature being alike in every part of the pipe. The exposed surface of the pipe was 287·244 square inches, and the quantity of water contained in it was 171·875 cubic inches. The rates of cooling were tried with different states of the surface: first, when it was in the usual state of cast-iron pipes, covered with the brown surface of protoxide of iron; next it was varnished black; and finally, the varnish was scraped off, and the pipe was painted white with two coats of lead paint."

The experiments to ascertain the cooling effect of glass windows are equally unsatisfactory.

"To ascertain the effect of glass windows in cooling the air of a room, the following experiments were made, with a vessel as nearly as possible of the same thickness as ordinary window-glass. The temperature of the room, in these experiments, was 65°; the thickness of the glass was ·0825 of an inch; the surface of the vessel measured 34·296 square inches, and it contained 9·794 cubic inches of water."

Then, again, the remarks on the quantity of heat derived from coal, founded upon the statement of other authors, and the effect which a certain quantity of hot water will produce, is by no means satisfactory. Why not have made a few experiments on different kinds of apparatus that are in use for warming of buildings? Every practical man knows the great difference in the consumption of fuel in various furnaces, and none more so than in the quantity of fuel consumed for heating of water for warming of buildings. To enable our readers to judge for themselves, we make the following extracts from the work:—

"It is stated by Watt, that 1 lb. of coal will raise the temperature of 45 lbs. of water from 55° to 212°. Rumford states, the same quantity of coal will raise $36\frac{8}{10}$ lbs. of water from 32° to 212°; and Dr. Black has estimated that 1 lb. weight of coal will make 48 lbs. of water boil, supposing it previously to be at a mean temperature. These quantities, when reduced to a common standard, vary but little from each other. Watt's experiment of 45 lbs. of water being heated from 55° to 212°, is equal to $39\frac{1}{4}$ lbs. only, if heated from 32° to 212°: and this nearly agrees with Count Rumford's calculation; at least the variation is not more than might be expected from a slight difference in the quality of the coal. Dr. Black's estimate is as much in excess over the experiment of Watt, as Rumford's is in defect; we may, therefore, take the average of these three experiments, which will give as a result, that 39 lbs. of water may be heated from 32° to 212° by 1 lb. of coal.

"To ascertain the effect which a certain quantity of hot water will produce in warming the air of a room, there appears to be no better method than that of computing from the specific heat of gases compared with water.

"Every substance, it has before been observed, has its peculiar specific heat. Now, 1 cubic foot of water by losing 1° of its heat, will raise the temperature of 2990 cubic feet of air, the like extent of 1°; and by losing 10° of its heat, it will raise the temperature of 2990 cubic feet of air 10°, or 29,900 cubic feet 1°, and so on.

"In order to know the time it will take to heat a certain quantity of air, any required number of degrees, by means of hot water contained in metal pipes, we must calculate the effect from direct experiment; and, as the radiating and conducting powers of different substances vary considerably, it is necessary that the experiment be made with the same material as the pipes for which we wish to estimate the effect.

"From the data obtained by experiments on the cooling of iron pipes, it appears that the water contained in a pipe 4 inches diameter, loses ·851 of a degree of heat per minute, when the excess of its temperature is 125° above that of the circumambient air. Therefore (by Art. 140), 1 foot in length of pipe, 4 inches diameter, will heat 222 cubic feet of air 1° per minute, when the difference between the temperature of the pipe and the air is 125°.

"To calculate the quantity of pipe that will be necessary to warm any particular room or building, and to maintain it at the required temperature, the heat lost by the necessary ventilation, and by the conducting and radiating power of the glass, and of any metallic substances used in the building, must be estimated.

"The calculations of the quantity of air required for ventilation, and the method of ventilating buildings, are considered in a subsequent chapter. (Chapter XI.) It is unnecessary, therefore, in this place to pursue the subject further than to state, that, in all public buildings, and rooms of dwelling-houses, a quantity of air equal to $3\frac{1}{2}$ cubic feet for each individual the room contains, must be changed per minute, in order to preserve the wholesomeness and purity of the atmosphere.

"The loss of heat in all buildings having any great extent of glass, we shall find to be very considerable. It appears by experiment, that one square foot of glass will cool 1·279 cubic feet of air as many degrees per minute, as the internal temperature of the room exceeds the temperature of the external air; that is, if the difference between the internal and the external temperature of the room be 30°, then 1·279 cubic feet of air will be cooled 30° by each square foot of glass, or, more correctly, as much heat as is equal to this will be given off by each square foot of glass; for, in reality, a very much larger quantity of air will be affected by the glass, but it will be cooled to a less extent. The real loss of heat from the room will therefore be what is here stated."

From such data do the author deduce the following rule:—

"From the preceding calculations, the following corollary may be drawn:—the quantity of air to be warmed *per minute* in [illegible] buildings, must be $3\frac{1}{2}$ cubic feet for each person the room contains, and $1\frac{1}{4}$ cubic feet for each square foot of glass; and for conservatories, forcing houses, and other buildings of this description, the quantity of air to be warmed *per minute* must be $1\frac{1}{4}$ cubic feet for each square foot of glass which the building contains. When the quantity of air required to be heated has been thus ascertained, the length of pipe which will be necessary may be found by the following

"RULE.—Multiply 125 by the *difference* between the temperature at which the room is proposed to be kept, when at its maximum, and the temperature of the external air; and divide this product by the *difference* between the temperature of the pipes, and the proposed temperature of the room: then, the quotient thus obtained, when multiplied by the number of cubic feet of air to be warmed *per minute*, and this product divided by 222, will give the number of feet in length, of pipe 4 inches diameter, which will produce the desired effect.

"When the pipes which are to be used, are 3 inches diameter, then the number of feet of 4-inch pipe, obtained by this rule, must be multiplied by 1·33, which will give the length of 3-inch pipe: or to obtain the quantity of 2-inch pipe, the length of pipe 4 inches diameter, obtained by the rule, must be multiplied by 2; the length required of 3-inch pipe, being one-third more than 4-inch, and the length of 2-inch pipe being double that of the 4-inch, when the temperatures are the same in all. * * *

"The quantity of coal necessary to supply any determinate length of pipe, is easily ascertained from the data given in Art. 138. After the water in the pipes is heated to its maximum, the quantity of coal consumed is, obviously, just what is required to supply the heat given off from the pipes. Now, by Art. 126 we find, that when pipes, 4 inches diameter, are 146·8° hotter than the air of the room, the water contained in them loses exactly 1° per minute of its heat. By Art. 138 we find that 1 lb. of coal will raise the temperature of 39 lbs. of water 180°; therefore, as 100 feet in length of 4-inch pipe contains exactly 544 lbs. of water, it will require 13·9 lbs. of coal to raise the temperature of this quantity of water 180°. If, therefore, the water loses 1° of heat per minute, or 60° per hour, this quantity of coal will supply 100 feet in length of pipe, for three hours, if its temperature continues constant with regard to the air of the room. * * *

"For estimating the quantity of pipe which is required to warm any building, rules of a much more facile character, though, at the same time, much more loose and inaccurate than those which have been already given, may easily be constructed; but they will answer sufficiently well in many common cases. Thus, in churches and very large public rooms, which have only about an average number of doors and windows, and moderate ventilation, by taking the cubic measurement of the room, and dividing the number thus obtained by 200, the quotient will be *the number of feet in length, of pipe 4 inches diameter*, which will be required to obtain a temperature of about 55° to 58°. For smaller rooms, dwelling-houses, &c., the cubic measurement should be divided by 150, which will give the number of feet of 4-inch pipe. For green-houses, conservatories, and such-like buildings, where the temperature is required to be kept at about 60°, dividing the cubic measurement of the building by 30, will give the required quantity of pipe; and for forcing-houses, where it is desired to keep the temperature at 70° to 75°, we must divide the cubic measurement of the house by 20; but if the temperature be required as high as 75° to 80°, then we must divide by 18, to obtain the number of feet of 4-inch pipe. If the pipes are to be 3 inches diameter, then we must add one-third to the quantity thus obtained; and if 2-inch pipes are to be used, we must take double the length of 4-inch pipe."

Thus it will be perceived not a single calculation is founded upon experiments made upon any apparatus in use. To our mind the only legitimate way of establishing anything like *practical data* to work upon, is to perform a series of experiments upon the different kinds of apparatus in use for warming by hot water; in such case the application of many of the author's calculations would have been serviceable. We trust that he will take an early opportunity of going more deeply into the subject than he has already done, and publish an addenda to his work; if he would perform such a set of experiments as we will point out, the work would then be complete and much more valuable. To obtain the particulars of every method now in use for warming of buildings by hot water, and all the information that can be collected, both from the inventor, and the party under whose care and management the apparatus is kept, to ascertain if it fully answers the purposes intended; carefully inspect the furnace and boiler, and take their dimensions; calculate their respective capacities; ascertain the method of setting the boiler, and length of draught of chimney; how the boiler is supplied with water; the respective situations of the inlet and outlet pipes; the dimensions and lengths of the pipes that are fed from the boiler in each room; the extreme distance of the pipe from the boiler; the relative positions of the pipes, whether the water ascends directly perpendicular, and feeds the pipes on the respective floors by horizontal branches, or otherwise; measure the capacity of each room and surface of glass; ascertain the aspect of each room; number of doors, and if they open into a passage or staircase warmed or not; the relative position of the pipes in each room, and the method adopted for ventilation. After having carefully ascertained all the before-mentioned particulars, then proceed with the experiments. Let the furnace be cleared from any fuel [illegible] in the boiler

and pipes is of the same temperature as the water in the cold water cisterns which supply the premises—then weigh the coals or fuel as it is put in the furnace, note the precise time that the fuel is ignited, and at the same time the temperature of the water in the boiler and pipes, also the temperature of the external and internal atmosphere: if possible, cause the bulb of a thermometer to be let into the boiler and the pipes in the several rooms that are to be warmed, the stalk of the thermometer to pass through an air or water-tight collar; let another thermometer be suspended in the middle of each room; employ several persons to note down every quarter of an hour, simultaneously, commencing at the moment the fire is ignited, the relative temperature of the external and internal atmosphere of every room, the water in the boiler and pipes, also the quantity of fuel consumed; when all these experiments have been made, and after the premises have been properly warmed, rake out the fire, ascertaining up to that time the quantity of fuel consumed, and in a similar manner as before note down the various degrees of heat, until the water be cooled down to the same temperature as at the commencement of the experiments. These experiments ought to be performed when the relative rooms are occupied for the purposes they are generally used for; the number of persons who frequent them should also be ascertained, and likewise if there be any general complaints regarding the ventilation.

Having thus performed experiments upon different systems of warming, and under a variety of circumstances, and in various premises, then endeavour to ascertain if there be any approximation in the relative quantity of fuel consumed to the space heated or ventilated; the cooling effect of glass, doors, &c.; the relative advantages of each system, and also the *cost* of the apparatus. Several other inquiries and experiments might be made, which would suggest themselves to an inquiring mind, and one that is disposed to go into the subject unbiassed, and with spirit and determination.

We have in some measure digressed from the work before us, which we hope our readers will excuse; we will now proceed to describe the remainder of the work. The next chapter is on various modifications of the hot-water apparatus, describing Kewley's Syphon principle, the high-pressure system, Eckstein and Busby's circulator or rotatory float, &c. The author then proceeds to give a general summary of the subject, containing some useful hints and information, which is followed by some judicious remarks *on ventilation*. The concluding chapter is on the different modes of distributing artificial heat, and the effect prodnced by hot-air stoves: at the end of the work there are several useful tables.

Notwithstanding the objections we have made (which are alike applicable to most, if not all other works on the same subject), we consider the work deserving of attention; it contains a great deal of useful information, and the author has taken considerable pains and trouble in the experiments he has performed, which will be found interesting to such persons as are desirous of studying the laws and nature of warming buildings by hot water.

Sectio-Planography. By F. W. Simms, C.E. London: John Weale, 1837.

This pamphlet explains Mr. Macneill's method of laying down railway sections and plans in juxta-position, showing at one view whether the railway passes through any particular property on a level or on an embankment, or in a cutting. To the professional eye it will give a clear view of the nature of the railway, how it will affect any particular property on the line, and the magnitude of the works; it is requisite, so as to make the drawings as clear as possible, that the embankment and cuttings should be coloured two different colours. In the New Standing Orders of the House of Commons of last Parliament, an order was made that all future railway plans should have the section laid down on the line shown in the plans, as recommended by Mr. Macneill, and explained by Mr. Simms in this pamphlet.

Railway Practice. By S. C. Brees, C.E., &c. J. Williams, 1837.

Among the many practical illustrations contained in this work, none are more deserving of attentive consideration than those of the works on the extension line of the London and Birmingham Railway. There is much to study, and a great deal to learn by the engineering student, in this portion of the railway; there are a greater variety of works, for its distance, than any other railway in the world. The designs for the bridge over the Regent's Canal display much ingenuity to overcome the difficulty of want of height for turning an arch over the canal; instead of which, sixteen ponderous transverse girders are obliged to be introduced, suspended to six massive cast-iron segmental ribs, spanning across the canal and towing-path, 50 feet wide in clear of the piers. There has been much judgment displayed in combining a bold architectural character in the design, which is frequently a difficult task to overcome when stone and iron are connected. The whole of the designs and working drawings of this bridge have been condensed into seven plates, which have also the advantage of the Specifications of the works being annexed. The next designs deserving of notice are those of the bridges under Park Street and the Hampstead Road; here, again, the engineer has had considerable difficulties to overcome, on account of want of height to turn arches, and also on account of the connexion of cross streets with the main road, which unite on the top of these bridges. Mr. Stephenson is certainly entitled to the highest praise for the taste he has displayed throughout the work on the London and Birmingham Railway; in no part of the line can he be challenged with having neglected architecture. He has given a character of beauty and simplicity to all his designs, without sacrificing the appearance of solidity and strength; there is no frivolity, or cutting up into small parts, nor appearance of weakness; every part clearly shows the duty it has to perform, and that nothing superfluous has been introduced, which is the beauty of architecture. Among the other drawings of the Birmingham Railway which are interesting and instructive, are those showing the method of working the Primrose Hill Tunnel: we regret that the editor has not given descriptive particulars of the working as well as the drawing. We have neither time nor space to go more fully into the work; but we will again avail ourselves of doing so the first opportunity.

A Practical Treatise on the Construction of Oblique Arches. By John Hart. Mason.

This is a treatise with several drawings, describing the method of cutting the stone, and setting oblique or skew arches, which the author has done in a very satisfactory manner. We recommend the work to the profession, contractors, and others connected with railways.

A Letter to H.R.H. the Duke of Sussex, with a Plan for the Promotion of Arts, Science, and Literature, by the moderate but effectual Assistance of Government. By Thomas L. Donaldson, Architect, F.R.I.B.A. London: J. Williams, 1838.

It is unnecessary for us to say much regarding this pamphlet; we cordially agree with its remarks relative to the heavy expenses incurred by scientific societies for rent and taxes, independent of other charges; we sincerely hope that Mr. Donaldson's efforts in calling the attention of the Government and the public to the subject will prove beneficial; it cannot be in better hands than the author's. We make the following extracts from the judicious remarks and suggestions contained in this pamphlet.

"The efficiency of many of those associations is much restricted by the limited means which they have at command. Those, which offer matters of general interest within the reach of the Dilettante and Amateur, as the Antiquarian, Geological, Horticultural, and Zoological Societies, may gather within their ranks as members a sufficient number of the lovers of each peculiar study, so as to acquire an income to meet their necessary expenses. But there are others, more strictly professional, such as the Institution of Civil Engineers, the Institute of British Architects, the Astronomical and Medical Societies, less attractive to non-professional members, and consequently not possessing that numerical strength which can enable them to establish an income adequate to the expenditure necessarily incurred by the house rent, the salaries of officers and servants, the institution of lectures and experiments, the collection of a library and museum, and the printing and other requisite disbursements, without which no society for the promotion of science can be effective. Besides, it is not fair that those who devote their time and professional experience to promote the purposes of such a society, should be further taxed in order to provide the entire pecuniary means to which reference has just been made. The very love of science induces them to come forward as they do; for it cannot be suspected for a moment, that affiliation to any association could add to the reputation of those men, from whose talents and zeal the chief advantages of such associations are derived. * * *

"The following table will show the average fixed income of several societies at the present period, resulting from the subscriptions and other contributions, and from the dividends:—

Names of Societies.	Annual Subscriptions.	Compositions.	Admission Fees or first year's additional Contributions.	Arrears.	Dividends.	Total.	Rent.
	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.
Royal Astronomical	172 0 0	42 0 0	38 0 0	43 0 0	65 0 0	360 0 0	105 0 0
Royal Geographical	416 0 0	323 0 0	117 0 0	48 0 0	168 0 0	1072 0 0	110 0 0
Royal Asiatic	488 0 0	478 0 0	68 0 0	15 0 0	58 0 0	1107 0 0	255 0 0
R. Med. & Chirurg.	466 0 0	....	202 0 0	....	....	668 0 0	210 0 0
Ins. Civil Engineers	483 0 0	....	....	....	69 0 0	552 0 0	108 0 0
R. Society Literature	439 0 0	....	....	....	8 0 0	447 0 0	228 0 0
Statistical Society	615 0 0	57 0 0	....	....	42 0 0	714 0 0	184 0 0
R. I. Bri. Architects	253 0 0	168 0 0	41 0 0	....	33 0 0	495 0 0	200 0 0

"The expense which is incurred by these societies in the rent for apartments affording accommodation quite inadequate to their wants, and, in many cases, in situations most inconvenient for their operations, weighs like an incubus, [illegible] at their first formation they are obliged to be satisfied with any apartments, however insufficient, in order not to incur too serious a rental. Some societies want but little accommodation, requiring only a mere meeting-room, ante-room, and library; but to others a museum also, and other apartments, are necessary. Still, in all cases, the rent presses most heavily.

"I would, therefore, venture to suggest, that Government could afford assistance to such Associations, at once effectual and little liable to abuse, by locating them suitably; in fact, by extending to other Societies that privilege which is now peculiar to the Royal Society, Antiquarian, Geological, and Astronomical Societies, and the Royal Academy of Arts. By this means their funds would be relieved from a material item of expense; and the fact of being in an edifice provided by Government, and as it were carrying on their proceedings with its immediate sanction, would give them a weight and importance, which no other method could produce so effectually or so unobjectionably.

"I should, in addition, suggest that Government should continue to afford those facilities for making important experiments, which it has hitherto granted at Woolwich and other public establishments, where the machinery and instruments at command are of that power, variety, and extent, which it is impossible for individuals, or Societies even, to possess."

Blunt's Civil Engineer and Practical Machinist. By CHARLES JOHN BLUNT, Esq. *Division B., Plates with Book.* London: Ackermann and Co.

WE are glad to see another part of this excellent work, which has many advantages over others of a similar description. In consequence of it being published on a large scale, all the plates are engraved from the original drawings of the engineer, without any reduction, thereby enabling any manufacturer or workman to understand them, and in many cases will save the necessity of making other drawings. The present part contains several important drawings, among which is the Lawley Street Viaduct, on the London and Birmingham Railway, together with the Specification of the work. There are also the drawings of the famous six-wheel "Bogie" locomotive engine and tender, manufactured by Messrs. Stephenson for the London and Birmingham Railway, and a similar engine, "The Hercules," manufactured by Mr. George Stephenson for the Newcastle and Carlisle Railway; also drawings of the Goods Waggons, with all their details, beautifully engraved and delineated. The last plate contains the drawings of the Maidenhead Bridge, on the Great Western Railway Line.

We hope the proprietors will proceed with the publication of the work with regularity, and produce one part, at least, every three months; we are sure the work will succeed if they will do so.

An engraved View of the Interior of the Chancel of Stratford Church, (the Mausoleum of Shakspeare), as restored from the Designs of Hervey Eginton, M.I.B.A. Engraved in outline by Thomas Turnbull, from a Drawing by W. Buttingfield, and inscribed to the Committee of the Royal Shakspeare Club.

THIS is a very fine outline engraving, showing the beautiful roof and alterations that have been recently made in the chancel of the church of Stratford-upon-Avon. In the "Gentleman's Magazine" of last month is a description of the repairs, from which we make the following extracts:—

"The repairs are now brought to a close, the most material defects in the structure having been substantially and tastefully amended by Mr Hamilton, under the superintending care of Hervey Eginton, Esq., Architect, of Worcester, who gave the design for the new roof. That gentleman was recommended to the Royal Shakspeare Club by John Britton, Esq., F.S.A., who has rendered very essential services in the renovation and adornment of this interesting building, as well by his excellent advice, as by the collection of large subscriptions in London and elsewhere.

"On the exterior, the works have been judiciously confined to essentials; that is, the replacing of faulty stones by new ones, and the renewal of the embattled parapet, with the addition of a handsome cross at the point of the eastern gable. The stonework of the two windows of the north wall next he east has also been renewed, their lower portions being filled up with stone (Shakspeare's monument is erected in one of them); but the mullions are made complete and uniform with the other windows.

"In the interior, the repairs consist of a thorough cleansing; a new pavement, in black and white lozenges, so far as the ancient stalls extend; a range of new altar-rails, of a pointed pattern; and, what is the most important work of all, a new oak roof. The ancient roof had been removed, probably during the last century, and a flat ceiling substituted. The new roof is supported by six arched ribs, which rest upon the ancient brackets, each of which is carved with three human heads. The design of the timber work has been carefully selected from buildings of a corresponding age, and their trusses are adorned with figures of angels holding armorial shields.

"The coats of white paint, inflicted by Mr. Malone, are still allowed to remain on [illegible]; but it is on record that the colours of the former were originally, the eyes a light hazle, the hair and beard auburn, the doublet scarlet, the gown black, the upper cushion scarlet, and the lower green, with gilt tassels. Why, then, should the restoration of its original appearance be delayed, particularly as all the colours might doubtless be verified on removing the present incrustation?"

REGULATIONS FOR STUDENTS IN CIVIL ENGINEERING OF THE UNIVERSITY OF DURHAM, PASSED BY THE SENATE AND CONVOCATION, NOVEMBER 22, 1837.

WHEN we consider the immense sums of money required to carry out any Civil Engineering project, the weighty interests involved in it, the ruin to individuals, and the loss to the country entailed by failure, the responsibility attaching to the Engineer is of no common kind.

The Engineer, to enter upon any task of magnitude, ought to bring to it natural talents, expanded by education, and strengthened by experience; he ought to be able to perceive at once, and to apply the maxims of science to the demands of business; he ought to combine the mind of the philosopher with the accomplishments of the mechanic; he ought to be a man of profound judgment; he ought to be able to decide not merely what to do, but what *not* to do; he ought to be accustomed not only to the abstractions of the study, but to the methods and manipulations of the workshop also.

A large proportion, in fact, the whole of the above mentioned qualifications so far as education and a rigid academic examination can effect them, will be induced by the system of regulations and course of study prescribed by the senate; and the practical application of the knowledge obtained at the college will be made most advantageously in the mining districts in the neighbourhood; without this combination of theory with practice, the student, when he enters into the world, will find himself loaded with a quantity of knowledge which he is more apt to forget, than to seek out the opportunity of applying to the advancement of the arts. We have been witness of some miserable failures in Mexico of German students, sent out by the English Mining Companies, in the hope that, inasmuch as they had obtained numerous honorary certificates from Freyberg University, they would be able to effect great improvements in the mode of working the mines, and the method for reducing the ores; we have seen several such men, and they were in every case distanced beyond all comparison by the every day knowledge of a Cornish mining captain; and in one case in particular, a German professor, high in academic honours, with a salary high in proportion, was intrusted to make a most extravagant outlay with the view of introducing the German system of smelting silver by the high furnace; he utterly failed, and was ultimately obliged to send to the "Hacienda of Regla" for the assistance of a German operative to teach him how to effect his own object. Such instances, with numberless others familiar to most practical men, point out the necessity of the students being placed in situations to obtain an insight into the minutiæ of the profession. In the College of Mines in Spain and Mexico, a student, after he has passed a certain period to study, is placed under the superintendence of a mining captain in some of the mines up the country; by this means, if disposed to learn, he has every opportunity to become an accomplished miner. So in the present case, after a student has passed three years in the college, he must consider his education but half complete, and should be articled for at least three years more to some man of business, who would give him the opportunity of perfecting himself in the technicalities of his profession.

The large sum required for a year's expenses, £100, precludes the possibility of any but the richer classes availing themselves of this system, and the Editor of the *Durham Advertiser* has fallen into error in supposing that the field for employment in Civil Engineering is so entirely disoccupied; the fact is the reverse; there is scarcely an opportunity left for a man of genius and learning to obtain employment, excepting through powerful interest; however, those parents who can give their sons such an expensive education, are not likely to be without the means of forwarding their views when their education is complete; the advantages will be great to the public, that men of education will then occupy those stations which, in too many present instances, are held by parties wholly unfit for them.

The regulations of the University meet our entire approbation, and we hope our suggestions may be of service to the parties interested in following them out in practice.

HYDRAULICS.

*Turbine.**—M. Arago lately called the attention of the Academy of Sciences to the *Turbine* erected by M. Fourneyon in the Foret Noire, an account of which had been previously laid before the Academy. M. Arago stated, that this machine is only one foot in diameter, and performs 360 revolutions per minute, under the action of a fall of water 108 metres (354 ft. English) high, with not more than a cubic foot of water acting permanently in the pipe: the useful effect appears to be equivalent to 60 horse power. At the time it was constructed (about a year since), objections were made that the machine would soon be out of order, in consequence of the extreme velocity with which it turns on the pivot. The inventor has, however, discovered the means of supplying oil in the step in such a way as to meet this difficulty. The method is a secret, so that M. Arago could not divulge it.

* A water-wheel on the principle of Barker's mill.—Editor.

ORIGINAL PAPERS AND COMMUNICATIONS.

DESIGNS FOR THE REFORM CLUB.

A general meeting of this club was held at their temporary residence in Pall Mall, on Wednesday, the 13th December, for the purpose of selecting a design for a new building. The architects who had forwarded designs, were Mr. Sidney Smirke, Mr. Blore, Mr. Cockerell, and Mr. Barry. These designs had been open to the inspection of the members of the club some weeks previous to the general meeting. The instructions issued by the Committee of Management appear to have been, to produce a club-house which should surpass all others in size and magnificence; one which should combine all the attractions of other clubs, such as baths of various kinds, billiard rooms, smoking rooms, with the ordinary features, besides the additional novelty of private chambers or dormitories. The site appointed extends from the spot now occupied by the present temporary National Gallery, on the one side of the present club-house, over the vacant plot of ground on the other side. This extent gives a frontage towards Pall Mall of about 135 feet. The Athenæum, in Pall Mall, occupies a space of 76 feet; the frontage of the Travellers is 74 feet; and that of the Conservative, or Carlton Club, 90 feet: the Pall Mall front of the new club will, therefore, be nearly equal to that of the Athenæum and Travellers together, and one-third longer than the Carlton. The introduction of chambers above the ordinary rooms of the club will render the elevation also about a third higher than its neighbours. The ground is rented of the Commissioners of Woods and Forests; and it is computed that the revenue of the chambers, calculated to yield from £1500 to £2000, will cover all expenses of ground-rent, taxes, rates, &c. The mode of letting these chambers, whether to members of the club exclusively, or to others, on long or short leases, has not yet been determined.

Premiums of £500 for the best designs, and smaller sums for the others, were offered; but we have understood they were declined by those gentlemen whose plans were not accepted.

At the general meeting, the choice fell upon the design of Mr. Barry. The preference was nearly unanimous; and, considering the purposes of the building, we are disposed, notwithstanding the several merits which each of the others possesses, to regard the choice as the right one. Independent of other advantages, Mr. Barry's plans entered into much fuller details, and conveyed a much clearer impression of all the various compartments, as well as of the whole of the building, than those of his competitors. He furnished, besides the ordinary plans, sketches of the effect of the more important rooms, in which was indicated the proposed mode of decoration. A similar advantage was possessed by Mr. Barry's plans of the Houses of Parliament. In that instance, too, they were the most numerous and complete. It seems obvious that it is as important to exhibit the perfection of the interior parts, and the architect's own views of all the details of a building, as to present the exterior elevation. And in the case of a club, the elegance, the convenience, and the appropriateness of the interior economy, require accurate specification, because they constitute the primary consideration. Nothing should be left to the imagination; and as a general principle, it may be laid down that no architect misbestows his labour in entering into all the minutiæ which elucidate his design. No complaint of want of explicitness can be made against Mr. Cockerell's designs, but it cannot be doubted that Mr. Blore's designs attracted less notice than their intrinsic merits entitled them to, solely on account of the scantiness and inexplicitness of their details. Not even the mensuration of his rooms was expressed. Surely mere outline of figure is insufficient to convey an accurate idea of length, breadth, and height. Next to the plans of Mr. Barry, those of Mr. Cockerell appeared to receive the approbation of the members.

We shall now proceed to give a brief notice of the features of each, beginning with the design of Mr. Barry, the successful candidate.

In the exterior, Mr. Barry has aimed to produce an elevation, in harmony with his own elegant Travellers' Club, and its neighbour the Athenæum; and, though producing a structure nearly twice as large as either, he has succeeded in not detracting from their importance, and in preserving the superior grandeur of the Reform Club. We fear he found it necessary to leave the Conservative to its chances.

Mr. Barry has evidently kept before him as a model, the celebrated Palazio di Farnese at Rome, designed by that mighty universal genius Michael Angelo Buonarotti, during the Pontificate of Paul the Third, A.D. 1545, and built by Antonio Sangallo. It will be remembered that the Farnese Palace contains the gallery of Annibale Carracci. Even with the necessary modifications, Mr. Barry's elevation fronting Pall Mall bears a very strong resemblance to the Farnese Palace, and the adoption of so splendid a model affords evidence of Mr. Barry's excellent judgment and correct appropriation of a design most suitable to the purpose. The new club, though consisting of six floors from the basement, will present in Pall Mall a frontage of only three from the ground. The basement and mezzanine below ground and the chambers in the roof being unseen. The entrance, like the Travellers, is several steps above the ground, and in the centre of the building in Pall Mall. There are four windows on each side of the entrance; nine windows equi-distant on the first floor, and the same number on the second. The pediments surmounting the windows on the first floor in Pall Mall are supported by Ionic pilasters; and at the back, overlooking Carlton Gardens, by Ionic pilasters, rusticated. The height of the ground and first floor is on the same level with those of the Travellers. A ballustrade, somewhat resembling that of the Travellers, rises from the ground. The whole design is one of massive grandeur. Our admiration increases with the examination of the arrangement of the interior details. An Italian court ($34\frac{1}{2}$ ft. by 29 ft.), beginning at the base, is placed in the centre of the quadrangle. And the apartments on the ground, first, and second floors are approached through corridors, lighted from the court, which on the ground and first floors are 9 feet wide. On the second floor the corridors leading to the lodgings are contracted to $5\frac{1}{2}$ feet. The area of the basement in Pall Mall is 9 feet wide, and in the gardens 8 feet. On the basement, every sort of culinary office seems provided, and located with singular judgment and convenience. The kitchen is 29 feet by 22 feet, and is fitted up with all the apparatus necessary for each peculiar system of cooking. The kitchen court is 23 feet by $14\frac{1}{2}$ feet; the steward's room 26 feet by $18\frac{1}{2}$ feet; butler's pantry $16\frac{1}{2}$ feet by 14 feet; the scullery 20 feet by 14 feet; the cook's room 17 feet by 12 feet; besides a host of smaller rooms, larders for pastry, poultry, and game, raw and cooked meat; hardware room, housekeeper's store-room; cellars for wine, ale, beer, and bottling. The number of apartments on the basement exceeds thirty. In the mezzanine or entresol, we find the butler's, housekeeper's, and still rooms; nine dressing and bath rooms of several kinds, vapour, shower, &c., and 16 male servants' rooms, besides the upper parts of the kitchen and larders, which enter this floor. On the ground floor, we have already noticed that the approach to the several rooms is through a quadrangle of corridors. The coffee room is the principal chamber, having a view into the gardens. Its length is 117 ft. by 28 ft., and is supported by Ionic pillars. There is a writing room, 40 ft. by 27 ft., adjoining to another room, to be appropiated to newspapers and periodicals, $28\frac{1}{2}$ ft. by 27 ft. The house dining-room, intended for private parties of the members of the club, is 29 ft. by 18 ft.: moreover, there is a steward's room, $16\frac{1}{2}$ ft. by 14 ft.; a waiting-room, 19 ft. by 14 ft.; two audience rooms, $12\frac{1}{2}$ ft. by $8\frac{1}{2}$ ft.; and a porter's room, $10\frac{1}{2}$ ft. by $9\frac{1}{2}$ ft. In all, nine apartments on the ground floor.

First floor.—The drawing-room is above the coffee-room, and of similar dimensions, 117 ft. by 28 ft. It is supported by Corinthian pillars, and so constructed that, if required, it may be divided into two or three rooms. There are two libraries, both supported by Corinthian pillars. The dimensions of the one are 40 ft. by 27 ft.; of the other, $28\frac{1}{2}$ ft. by 27 ft. There are two billiard-rooms on this floor; one 22 ft. by 18 ft.; the second 23 ft. by $17\frac{1}{2}$ ft. The committee-room is $33\frac{1}{2}$ ft. by $17\frac{1}{2}$ ft. An accountant's room, 13 ft. by $7\frac{1}{2}$ ft.; and a small reading-room, 12 ft. by 10 ft.; members' private room, 17 ft. by 13 ft.; and waiting-room, 20 ft. by 14 ft.

The second floor is disposed of in twenty-six chambers or lodgings, the dimensions of each varying from 22 ft. by 14 ft. to 12 ft. by 10 ft.

There are about thirty-one rooms in the attic floor, which are intended for the female servants of the club, and the servants of the renters of the chambers. We have here upwards of 134 several apartments in this building; the judicious disposal of which can only be duly estimated by reference to the plans themselves, and these we hope to place before our readers hereafter.

The cost of realizing Mr. Barry's design is estimated at £45,000, and at present it is proposed to commence active operations in June next.

We are compelled to be somewhat brief in our account of the designs of Mr. Cockerell and Mr. Blore; of those of Mr. Cockerell, because we have only enjoyed a temporary glance at them; of Mr. Blore's, because the mensurations are not specified. The most striking feature of Mr. Cockerell's designs, was the magnificence of the hall and staircase. None of the others could compete at all in this respect with Mr. Cockerell's. The front, towards Pall Mall, presented three floors above the ground, and a series of nine windows in each. Between those on the first and second floors, were placed massive Doric columns. Mr. Cockerell appeared to employ the whole of the utmost length for his frontage; and certainly his designs conveyed the impression of a much larger and heavier building than the others. The number of the floors was the same—consisting of a basement, a mezzanine, ground, first, and second floors; and the number of the rooms, we think, exceeded that of Mr. Barry's design. After Mr. Barry, Mr. Cockerell's designs were most worthy of choice, though, as a matter of taste and fitness, we prefer the exterior elevation of Mr. Blore to that

of Mr. Cockerell. Mr. Blore adopted the modern Italian style. His Pall Mall front is of much simplicity and elegance, the entrance being in the centre, with three windows on each side. The garden front is more ornamented. In this, Ionic pilasters support a balcony on the second floor. A balustrade rises from the ground.

The basement floor comprises about twenty-two rooms, viz., the kitchen, scullery, cook's, coffee and still, housekeeper's, servants', butler's, larders, and cellars. The lower mezzanine is appropriated to servants' bed-rooms, baths, and dressing-rooms. On the ground floor are the coffee, morning, serving, billiard, and private dining-rooms. On the first floor, the library, drawing, committee, serving, billiard, and secretary's rooms. The upper mezzanine is occupied with seven bedrooms, and the upper part of the library and drawing-room.

The second floor is disposed of in lodgings.

The exterior elevation of Mr. Sidney Smirke's design is very different from all the others, partaking of the character of a highly ornamented Corinthian temple, and, though magnificent and imposing, appears not altogether most appropriate for a club-house. The entrance and principal front is at the western side of the ground, opposite the Conservative Club. This consists of a grand portico of four Corinthian columns. This spot is too close to the Conservative Club to exhibit a large portico to advantage. Indeed the portico, which is the most striking feature in Mr. Smirke's design, is so placed, that its effect is wholly destroyed by its proximity to the opposite building.

His Pall Mall front, like the other designs, has three floors, and presents a series of seven windows on each. The building is surmounted by a balustrade. It appears to us that the exterior is little in harmony with the surrounding buildings, and that it is not applicable to a club-house, which seems to require internal convenience rather than profuse external decoration. But it is upon the exterior that Mr. Smirke has bestowed all his attention in this design, and for the sake of his portico he has sacrificed a considerable portion of space. His Pall Mall frontage occupies only about 110 feet, whilst there were nearly 140 feet available. Under the circumstances, we do not think 30 feet, or thereabout, should be given up to a portico which nobody could see. We fully admit the beauty of the design, while we dispute its appropriateness.

The basement comprises the kitchen (33½ ft. by 33½ ft. and 24ft), scullery (22 ft. by 18 ft.), cook's room, servants' hall (25 ft. by 21 ft.), men's cleaning room, larders for dressed and raw provisions, fish, vegetables, beer, wine. On the mezzanine there are thirty rooms, consisting of a billiard-room (28¾ ft. by 23 ft.), bath and dressing-rooms, men's sleeping-rooms, rooms for butler, steward, housekeeper, &c. On the ground floor, the entrance hall occupies 33¾ ft. by 23 ft., and the principal staircase 64 ft. by 33¾ ft.; the secretary's room, 20 ft. by 15 ft.; waiter's room, 22½ ft. by 18½ ft.; house dining-room, 32 ft. by 29 ft.; a morning-room, 62 ft. by 32 ft.; and the coffee-room, which looks into Pall Mall, 110 ft. by 32 ft.

Above the coffee-room, on the first floor, is an evening-room, 110 ft. by 32 ft. and 68 ft. There are two libraries, which open into each other, the dimensions of each being 50 ft. by 32¼ ft.; and a committee-room, 23 ft. by 19 ft. on the same floor. On the second floor there are twenty-two rooms, many united, which are intended for chambers; they are approached by a corridor, around an open area, over the roof of the principal staircase. Besides, there is a smoking-room.

RALPH REDIVIVUS. No. 1.

SOMEWHAT more than a century has now elapsed since the first appearance of Ralph's "Critical Observations on the Public Buildings of London,"* which has since continued to be a sort of stock book and authority for architectural opinions. In its day, it may be allowed to have deserved the repute it acquired, were it only as an attempt to popularize criticism on the subject it treated of; but even those who still appeal to it must allow, that it is now somewhat *passé*. During the last hundred years we have both learnt and unlearnt much in regard to architecture. We have become acquainted with Grecian architecture, and discovered it to be something very different from what had been previously imagined by those who received the Roman and modern Italian versions of its orders as indubitably exact copies of their Hellenic and Asiatic prototypes. Even a penny a-liner would now be ashamed of calling Jones's building at Whitehall Grecian, or applying the same epithet to St. Paul's. We have learnt that the orders, as practised by the Greeks themselves, were of a widely different character from those traditionary copies of them which had been so long received as legitimate, and to which the utmost perfection was ascribed, as being the genuine productions of a people who had carried the arts to the highest pitch of excellence. Besides that the taste they exhibited in regard to detail, form, and composition, was utterly dissimilar from that manifested in the productions of the so-called classical Italian school; it has recently been discovered that it was still more at variance with doctrines hitherto generally established, inasmuch as colour—*lithochromy*, or *polychromy*, was resorted to by the Greeks, for purposes of exterior embellishment, even of columns; and that a fanciful luxuriance in this respect prevailed in buildings which were otherwise in a severe style of art. On the other hand, again, the Gothic style, which used to be reprobated in Ralph's time, as unworthy the name of *regular* architecture, as the offspring of ignorance and bad taste, as devoid of all harmonies and proportion, as fitted only for monkish, gloomy, and barbarous edifices, has not only been amply vindicated and taken into favour, but has been advocated by some in terms of exaggerated, if not of exclusive admiration. While they contend that it is our national style *par excellence*, they assert that the beauties of its Grecian rival sink into insignificance and insipidity in comparison with it.

All this must necessarily have had some influence upon opinion and criticism, in consequence of which different views are now entertained of the art from what were held a century ago. Even had nothing of the kind alluded to happened, still even the mere increase of buildings since the time of Ralph, particularly in our day, and of late years, would somewhat alter the estimation which many obtained two or three generations earlier. All merit is comparative; nor is there any exception in this respect, as affects productions of architecture, any more than those of literature. A few standard works survive, the rest are neglected; and whether such ought to be the case or not, such or nearly such is it in regard to architecture.

Time was, when anything bearing a decent resemblance to an ancient portico was cried up as a phenomenon, a portent, or prodigy. Good-natured critics were in absolute ecstacies;—they talked not of the "age of Periwinkles," for they had hardly then reached that *pons asinorum* of erudition, but they did what answered their purposes as well—descanted on Vitruvian proportions, on harmonies of the most volatile and ethereal quality, yet easy enough to be caught and brought into subjection by a foot-rule; lastly, they promised that *ne plus ultra* of immortality to the lucky wight to whose conception the world was indebted for such a masterpiece, predicting that his reputation would last

"As long as Atalantis shall be read!"

But, alas! for the treachery of fame! the reader here stops to inquire who, or what was Atalantis; for which information he is desired to step either to the Moon or the Museum.

"Since all things lost on earth are treasured there,"

—in one of those two capacious repositories.

Lest the reader should imagine, from this very curveting strain, that we have fairly sent thither both our wits and our subject, or that we occasionally get astraddle on a hippogriff, let us descend a little from our flight, and curb in that restive Pegasus, our pen; especially as we shall else be reminded, that we are nothing akin to our worthy predecessor Ralph, whose staid—and not to speak it profanely, rather prosy mode of criticism, is in altogether a different strain—one which may be said *sentir de la perruque*. Therefore, instead of losing time in hunting after the thread of our argument, we will not exactly commence *de capo*, but start afresh by asking, who now talks of the "magnificence of the Adelphi," or Portland Place? Who, save some antiquarian Dr. Dryasdust, can find any interest in the heavy uncouth city churches? which, with here and there an exception, partake as much of classical taste, as a Dutch burgomaster does of the Antinous. Who, again, regrets that old St. Paul's School has been swept away; or that the Warwick-lane College of Physicians has been converted into a butchery, and the carcases of prize sheep and oxen hung up beneath what was its anatomical theatre? Old St. Dunstan's, with its clock, one of the sights and wonders of cockney-land, has been swept away; and even that venerable piece of most orthodox ugliness, Exeter Change, has similarly fallen a victim to innovation and improvement. Serjeant's Inn, that curious and highly instructive specimen of what our metropolitan street architecture used, at one period, to be, has still more recently disappeared; owing to which the physiognomy of that part of Chancery-lane has assumed a totally different character, so much so, that the opposite neighbours doubtless wonder to what new region of the town they have been transported.

In fact, mutation is busy everywhere: Algiers has had a narrow escape from being Parisianized; Egypt is getting every day more European, not to say Londonized; the land of the Pharoahs will, ere long, be traversed by railroads and steam-vessels; and could our old friend Ralph revisit earth, he, too, would doubtless feel a change come over him, and somewhat modify, if not entirely alter, some of his opinions, including that wherein he is so liberal of admiration towards the east end of St. Martin's Church, which he pronounces to be "remarkably elegant, and justly challenges particular applause." As, however, we cannot recall that worthy from the tomb in *propria personae* we adopt as the very next best course, that of masking ourselves in his habiliments, trusting that in so doing we shall exhibit quite as much ability, not very much less quantum of *nous*, and, perhaps, a grain or two more taste. We have certainly a far ampler field before us than he had. Not only are there numerous fresh subjects of the same sort he had before him, but various classes of others which did not then exist. We have now an entirely new genus of palazzo-like edifices—the club-houses; another under the denomination of arcades, although here we are afraid we must as yet restrict ourselves to the singular number, there being only the Lowther, unless we add to it that on the west side of the Opera House, that makes any pretension to architectural effect. Besides these, and other novelties, there are one or two others altogether *sui generis*: for instance, the Pantheon Bazaar, and the Colosseum.

The building we shall first speak of—but it is now too late to think of

* It is exceedingly doubtful whether Ralph was really the author of the "Critical Remarks," or merely adopted the offspring of another man's brain. Incredible as it may appear to those who, uninitiated into the mysteries of literature, regard a title-page as an affidavit, the latter case has happened frequently ere now, both before and since Ralph's time. What tends in some degree to confirm suspicion in regard to him is that although he was rather a prolific writer, the "Remarks" are the only piece of the kind professing to come from his pen.

making a formal beginning at the conclusion of a preliminary, whose length has left us little space, and whose tone is not exactly accordant with that of sober criticism, nor such as we mean to indulge in in our future papers. Bating the other differences, and that it is less egotistical, and not so ambitiously pathetic, our present scribbling is somewhat à la Preliminary Essay by the learned antiquary of the firm of Faraday and Co. Every thing must have a beginning; and should ours be after a fashion the reader likes not, we hope to satisfy him better when we next meet.

REMARKS ON COMPETITION ESTIMATES BY AN ARCHITECT.

Sir,—In your last number a correspondent expressed himself upon the subject of competition estimates, and reflected properly upon the mode occasionally adopted both in obtaining estimates and fulfilling contracts. The writer is probably an architect; let me offer him a few suggestions, and while in full reciprocity I acknowledge evil does exist among building branches, request him to unite in condolence with one who laments that the profession also has its full share; this done, relieved by confession, we may set to work and clear the grey hairs from our neighbour's wigs, without fearing the return of the same kind offices on our own. First, then, when a city district was lately to be surveyed, competition estimates were given, a highly talented architect offered his services for 200*l*.; an equally experienced brother estimated the value of his services at very nearly the same cost; when, lo! a much *greater man* than either undertook the same matter for 40*l*.!!! The parish of Lambeth was to be surveyed, two well-respected gentlemen estimated the labour at 6,000*l*.; in utter defiance, others offered to execute the Herculean task for 1,200*l*., and the gradations between, ascended in *sol. fa. accordana* from a host of expectancies: 2,400*l*. were the closing terms. Workhouses! but they are a tender subject, have not they been done wholesale at half the usual remuneration? and in consequence, did not the Reform Club House Committee offer to three distinguished architects terms which would have unstrung the nerves of a Jew orange boy? and did they not barter and cheapen, until they found that talent and honourable pride and gentlemanly feeling would no longer submit to so derogating an outrage upon the customary tribute to its worth? To all this, without bringing forth devoted instances of architects acting gratuitously to public bodies for sinister motives, as now the case, or of mentioning little circumstances of forty architects voting each his own work better than his successful rivals, to all this let us plead guilty, and prepare for building crimes.

There is not an architect, there cannot be a surveyor who has not been most artfully dodged by some one of the genus of undertakers, contractors, or otherwise, as they may be defined, who has not been obliged to risk his neck, spoil his nether garments, and burn his boots through with lime, in the double duty of increasing the quantities of good material and decreasing the superfluity of the worthless; who has not multiplied writings, written notices, arrested progress, and stopped payments, his own, of course, in the act; and all because the figure in the thousands had been wrongly cast in the builder's estimate, or that the builder had laid a good-humoured plot of doing the work entirely at the expense of his timber merchant, and by way of practical joke upon the architect, compelling him to work doubly for one half the otherwise amount of his commission. It is not to be wondered that such annoyances should prompt the wish to root up the system of competition altogether, to bring back the times when work, if done well, was well valued; or, if ill done, proportionately paid for. But let us not vainly endeavour to arrest the march of emulation; rather let us see where the objections lie, and trace them to its origin; in fact, let us, in the same spirit of candour with which we set out, confess ourselves the springing stones of offence. Few will deny the advantages of well-conducted competition; it is an honourable stimulant to mental energy, to the powers of arrangement, invention, and calculation; it tends to simplify, perfect, and economize constructive art; it maintains the equality and moderation of the several sources of supply; and it produces for ordinary use, at reasonable prices, that which monopoly would prohibit, but to the rich. The broad assertion, that works done by contract are worse executed than others for which a different principle has been adopted, is not true; the execution of our public works does honour to the names of our large contractors. Contract work is only ill done when the architect, or the employer, thrusts into the competing list, one of little talent, small means, and no principle. Talent in a contractor is as necessary for the executive as genius and science for the design. A large plant and unlimited credit is indispensable for excellence and dispatch. The want of principle is an evil increased by the addition of the two former qualities. A contractor who undertakes a building 40 per cent. below a remunerating price (no uncommon occurrence) can have but one of three motives, either to evade or supersede the contract, or cheat his merchant by compounding or insolvency. Let, then, the profession carefully sift the means, pretensions, and characters of contracting builders; let them apportion to them, according to their respective means, the different classes of engagement; let them, above all, found their own calculations upon those chances of depression only which may follow from superior management and greater facilities of trade, and not moderate their estimates upon the probability of those ruinous contingencies which fraud or miscalculation so frequently produce; let them do this, and they will no longer be stigmatized as the supervisors of insecure works, nor lament that the system of contracting, as it now operates, doubles their labours, while it halves their incomes.

Yours, &c., AN ARCHITECT.

GRAND JUNCTION CANAL RESERVOIRS.

Upon this extensive line of canal there are eight reservoirs, and all of them are between the summit level and its northern extremity, at Braunston, where it joins the Oxford Canal. The summit level, which is 3¼ miles in length, is situated within one mile and a half of Tring, in Hertfordshire: this level is 57 feet above the junction at Bramston, and 395 feet above the River Thames. The lowest intermediate level is that at the aqueduct, near Stoney Stratford, in Northamptonshire, which is 192 feet below the summit at Tring. A second summit is situated near Daventry, which is 37 feet above the junction at Bramston. To maintain a supply of water to these summits, the eight reservoirs are appropriated; six to supply the Tring summit, and two to supply the Daventry summit. Their contents and extreme depths are as follows:—

Reservoirs.	Contents in Locks of Water.	Extreme Depth. Feet.
Daventry	7205	35
Drayton	1337	26
Marsworth	994	18
Stanhope's End	2296	24
Tring	1016	20
Wilston (Old)	1413	15
Wilston (New)	1413	18
Weston	1856	22

Each lock is computed to contain 9000 cubic feet of water.

It so happens, that not one of these reservoirs are on the same level with that of the summit at Tring, but are at various levels; the highest and nearest one, which is Marsworth, being 31 feet (nearly) below it. Consequently steam power is necessary to raise the water from one reservoir to another, and to the summit level, which receives but a very small supply from springs in the immediate vicinity, and which small supply has been recently diminished by the deep cutting on the London and Birmingham Railway, which is near at hand, and being much lower than the level of the canal, has cut off some of their supply.

The *principal steam engine*, and that which *pumps the water into the summit*, is the one nearest thereto, called in the neighbourhood, the Tring engine: some of its dimensions, &c. are as follow:—

	Ft.	Inch.
Length of beam, from centre to centre	24	8
Interval between the centres of the lifts	9	8¼
Length of stroke	7	9
Diameter of cylinder	4	0
Lift of water, when the reservoir is full	27	2

A 32-inch bucket is used until the water is lowered 19 feet, when a 28-inch bucket is substituted.

The consumption of coals is said to be 1½ cwt. per hour at a 40 feet lift. The engine is also said to work at twenty-four pounds pressure, and make ten strokes per minute, and to pump up about eighty locks, of 9000 cubic feet each, in twenty-four hours. The power is estimated at about 70-horse.

This engine has recently (we believe within a year) been clothed after the manner of the Cornish engines, about the duty of which so much has been said. Before the alteration, the radiation of heat from the boiler was so great, as to render it extremely unpleasant to enter that part of the building; but after it had been clothed, a person could walk on its top without feeling the surrounding temperature higher than would be necessary for an ordinary apartment. The manner in which this is accomplished is by covering the boiler with sawdust, which is a non-conducting substance, and this covered with bricks laid dry; the cylinder is cased with wood, and the interval between the cylinder and case in like manner filled with sawdust.

Between Blisworth and Stoke Bruern, in Northamptonshire, there is a tunnel, on the line of canal, 1¾ mile long, through the same range of high ground that the deep cutting on the Birmingham and London Railway is made, where that eminently scientific engineer, Mr. Stephenson, has executed a most interesting work in the undersetting of a rock.

REMARKS ON "OBSERVATIONS ON THE NEW HOUSES OF PARLIAMENT."

Sir,—In perusing the last Number of your valuable Journal, I find one article which, I think, deserves and desires refutation from an abler pen than mine; I hope, however, that the few remarks which I am about to make will be sufficient to show the absurdity of the propositions made by your correspondent in his "Observations on the New Houses of Parliament."

He commences by giving his qualifications to judge, and his reliance on that judgment, which it appears has been formed by "extensive travels through England, France, Italy, and Germany," by the performance of which tour, he considers himself equally qualified to judge with those who have made architecture the study of their *lives*, and not merely devoted "hours" to its attainment.

I will now examine his first interrogation.—"With what view," he asks, "has the proposed site been chosen by the architect?" If your correspondent had referred to the original notice to architects who were desirous of competing for the building, he would have seen that the site was pointed out, and that they were limited to a certain space; and this was issued by the Commissioners.

If, therefore, any blame is attachable for the selection of the proposed site, the architect cannot in any wise be deemed responsible, and it was not, therefore, in Mr. Barry's power to act in accordance with the suggestion of Vitruvius, which your correspondent, in his infinite wisdom, deigned to point out. Again, in his appellation of St. James's Palace, "a vile heterogeneous fabric," he is altogether mistaken, and I doubt much whether, in his vast travels, he ever reached the interior, or he would not have been so determined in his judgment; neither can he be aware, that it is impossible that a court can be holden in the Buckingham Palace, which the demolition of St. James's

would render necessary. With regard to the exterior of the latter, few can admire it; but the very fact of its containing eight of the largest rooms in Europe, would secure it from destruction; at least, in the mind of any reasonable and unprejudiced person.

Your correspondent then favours us with a *very* vague idea of the plan which he considers the best to adopt. Surely this is unkind—why did he not remember his duty to his countrymen before, and at the due season have furnished a plan which he considers so truly beneficial?

But his great mind condescends to lower itself, and apply its task to articles of furniture. He considers that the throne should merely be a *simple "chair of British oak*, with a velvet crimson cushion."

We should imagine from his style, that "during his extensive travels" he had devoted a few hours to the art of Upholstery.

I had hoped, in perusing the commencement of his article, that his taste had been so far formed by travelling, as to delight in the beauties of antiquity; but I was miserably disappointed when I *reached* the paragraph in which he had the hardihood to assert, that "Henry the Seventh's Chapel has now the same *begrimmed* complexion as its parental Abbey."

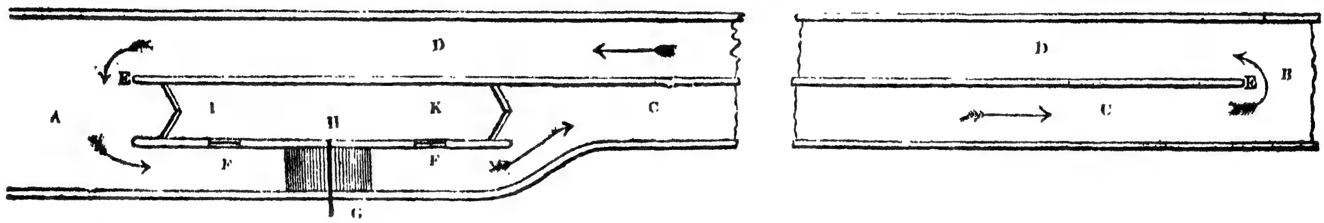
I appeal to you, sir, whether it is possible to look to that man for sound judgment, or refined taste, who designates the Cathedral Church of Westminster "an old MURKY Abbey, from which the sweepers might collect at least one hundred bags of soot!!!"

He seems to consider, that in the brightness and cleanliness of the exterior face of a building, consists a beauty which cannot by any means be surpassed, and that the selection of the site and stone, which will render those beauties most lasting, should be the principal object for the solicitude of the architect. I very much question whether Mr. Britton's opinion on such matters at all agrees with that of your correspondent. He is not aware that the means which he proposes to pursue in order to prevent the execution of Mr. Barry's design have already been agitated, and were unsuccessful. He concludes by saying, that he knows not the man—neither do I—but this I do know, that all structures which have been executed under his superintendence, will bear the strictest scrutiny, aye, even of a *Continental Tourist*.

I will not trouble you further than by observing, that it is a pity but that amateurs should be more circumspect in the opinions which they assert; seeing first that those opinions are well grounded by the study of that art which they attempt to deteriorate. I argue, sir, that it is impossible for a casual observer of the architectural beauties of this or *any other country* to acquire that knowledge which alone can be attained by industrious and indefatigable study.

C. W. I.

IMPROVEMENTS ON CANALS AND THE MOTIVE POWER THEREON.



At page 27 of our Journal the reader will find, among the patents there mentioned as having been granted between the 28th of September and 26th of October last, the following record:—"Henry Robinson Palmer, of Great George Street, Westminster, Civil Engineer, for 'Improvements in giving Motion to Barges and other Vessels on Canals;' 20th October." We are now enabled to lay before our readers some particulars of the method adopted by Mr. Palmer, and which forms the subject of his patent: these particulars we believe to be the first laid before the public.

Mr. Palmer, who, it is well known, has had extensive experience in canal and hydraulic works, has for a length of time devoted his particular attention to that complicated, and at present very imperfectly understood, *theory of rivers*, and has made a very extensive and important collection of experiments in various rivers and canals; and, from the discussion of these experiments, we sanguinely look forward to some additional light being thrown upon that difficult and important subject. It was, as we understand, during these investigations that Mr. Palmer contrived the canal improvements which form the subject of his patent, and of which we shall now attempt to give some idea; but it must be understood, that the engraving at the head of this article is not drawn to any proportion, but is a *sketch only*, to give a knowledge of the plan; even the details of the arrangements may possibly undergo considerable alterations by Mr. Palmer, in carrying his plan out on a large scale.

Each pond of the canal, as AB, is divided into two parts or channels C, by a wall EE; a third and short (or side) channel FF is also formed by another wall, in which two sluices I and K are inserted; these sluices connect the short channel F with a lock formed by two pair of gates in the channel C; at G, in the side channel, a *fen*-wheel, similar to an undershot water-wheel, or the paddle-wheel of a steam-vessel, is fixed, to which motion is communicated by steam or other fixed power; the revolution of this wheel communicates motion to the water in the direction from F to C, and (as it will readily be perceived) in the direction of the arrows, through the whole length of the channel C, round the extremity E of the pond, along the channel D to the further extremity, and again beneath the wheel G, and then by C, as before. By this simple, but admirable contrivance, the traffic can be conveyed in both directions, and to any extent whatever, by the same power, which, if steam be the power used, can also at the same time be employed in working the machinery of corn or saw-mills, &c., according to the demands of the neighbouring locality, and very advantageously, as the canal affords a ready means of conveying the raw material to the mill, and the subsequent produce to the distant market.

The introduction of the lock H in the channel C, appears to be the maintaining of the current in the direction of the arrows, as above stated, or the wheel would not produce the desired effect, it being necessary for the wheel to be kept out of the main channel C, that the motion of the traffic may be uninterrupted; the lock is to be so constructed, that a passing barge shall push the gates open before it for its passage: thus, suppose a barge was passing from A towards B, it approaches the lock H with whatever impetus it may then have, the sluice I is opened by a lock-keeper, who may also have charge of the steam-engine; upon this sluice, or valve, being lifted, the water will pass from the lock, by the motion of the wheel, into the channel F and C, leaving the surface of the lock at a lower level than that of the channel D; and as the gates open inwards, the water, together with the impetus of the barge, will open them, and the barge will enter the lock, and the gates will again close; this done, the valve K is to be opened, which producing a current in the direction C, enables the barge to push open the second pair of gates, and so pass on in the direction of its route: the passage of these locks will delay the barges so little as not to be worth noticing.

A LETTER FROM MR. G. GODWIN, JUN., A.I.B.A., ON HITCH'S "PATENT REBATED BRICKWORK."

SIR,—The geological position of London has rendered bricks the principal material used for building in the metropolis, and one might reasonably expect that any reputed improvement in their construction—any invention tending to lessen the cost of brick edifices, and at the same time increase their durability, would be immediately investigated by those interested in the matter, and universally adopted if found effective. Men, however, individually are averse to change; they view any new invention, any fresh road, as they receive any new truth, with great caution, if not mistrust, and prefer following a path which they have before trodden to venturing on one recently opened, although assured that it would save them half the distance; generally neglecting to profit by the information, until it has been again and again reiterated and re-urged. Under some circumstances, perhaps, it is fortunate that this is the case, for excellence is of slow growth, and constant change would sadly militate against perfection. Still the result, to individuals and to science, is oftentimes disastrous. An ingenious man having, by the sacrifice of property, and the exercise of his faculties, perfected an invention of real value, obtains a patent, and seeks the reward due to his skill and ingenuity; before, however, the mistrust of which we have spoken is overcome before the public will venture to inquire for themselves, or be persuaded to avail themselves of the advantages which he demonstrates, the term of his patent, in many cases, expires, and others less deserving, but more politic, receive the advantages in a pecuniary point of view which should have been his. The inventor of the new method of building, respecting which I am about to speak, will not, I trust, prove a case exactly in point, his system being now (as indeed it has been for some years past) pretty extensively used in the county of Herts—the locality of the patentee—in Essex, Hampshire, and elsewhere. Still its reputed advantages are not known in the metropolis, and I now beg, solely with a view to inquiry, and from a desire that "the race *should be* to the strong," to communicate, through your pages, such knowledge of the matter as I have gained by experience. I cannot enter upon the subject so fully as I would do willingly

were my time less occupied than it is; but hope that what is said may induce an investigation of the system on the part of others better qualified to guide the public than myself.

The invention comprises, first, a peculiar formation of the bricks, which are of large size, and present a bold and uniform face; and, secondly, the introduction of concrete, formed of lime and ballast, in the construction of the wall. The bricks, moulded in various forms to suit the several offices of headers, stretchers, bat-headers, &c., are all so made as to dovetail into each other, and to present in the interior of the wall a series of cavities communicating with each other by means of dowel-holes through all the bricks. Into these cavities, as the work proceeds, concrete is introduced, and thus the whole wall is rendered a solid mass. The cost of the work varies from 20 per cent. to 50 *per cent. less than the cost of ordinary brickwork*, according to the thickness of the walls; which saving, it would seem, is effected through the difference in price between concrete and brickwork, the smallness of the quantity of mortar required, and the diminution of labour occasioned by the size of the bricks. Where an extraordinary degree of strength is necessary, iron rods can be introduced through the dowel holes, and the greater the thickness be that is required, the greater is the saving, compared with common brick, which would be attained.

The patent was obtained in the year 1828; but my own experience will not carry me farther back than 1832. About that time I used the rebated brickwork in stabling and office-buildings (as I have done in many instances since, as well as for more important purposes); and the whole of the works stand remarkably well. I had occasion last week to cut into one of the walls so constructed, and I may safely say, that it had become a complete rock, and for a long time resisted all the efforts of the workmen.

The appearance of the work when completed is good, and if it be coloured, it has, from the large size of the bricks (12 to 15 inches long, and 5 inches high), the aspect of ashlar.

Garden walling is executed with dowelled bricks at little more than the cost of common wood fencing; and walls so built possess several advantages over ordinary brickwork, especially in regard to horticultural purposes. For example, the mortar joint being very small, is less liable to afford harbour for insects, and when injured by frost, &c., may be repaired at little expense. There are in the Royal Gardens at Hampton Court several walls thus constructed.

The same clever individual, Mr. Hitch, has also made a variety of wedge-shaped arch bricks, with a view to avoid the large mortar joint which necessarily occurs in arches constructed of common bricks; and several bridges have been built with these in various parts of the country. I have used them in many instances for vaults with advantage.

In concluding this hasty notice, permit me to observe, that the subject of brickwork in general, as at present executed amongst us, offers many points for consideration and inquiry, and well deserves a greater share of attention from the architectural student than it usually receives. With your permission, I shall offer, on some future occasion, a few remarks touching constructions in brick, and the ordinary methods of bricklaying; and in the meantime subscribe myself,

Yours, &c.,

Brompton, *Dec. 9th*, 1837. GEORGE GODWIN, JUN.

CURTIS'S RAILWAY CHAIRS.

The form of the rail R, and chair C, as shown in Fig. 1, is the same as those now in use; but the space for the key is made rounding in the middle, as shown in Fig. 3.

Fig. 1.

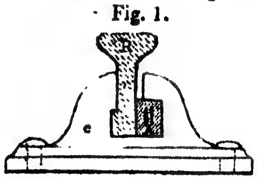


Fig. 3.

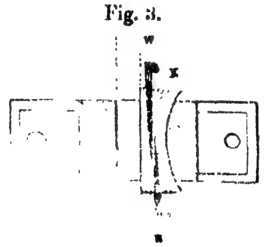

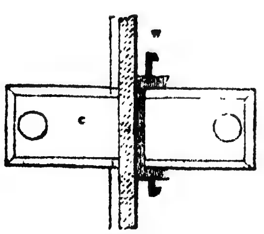

Fig. 2.

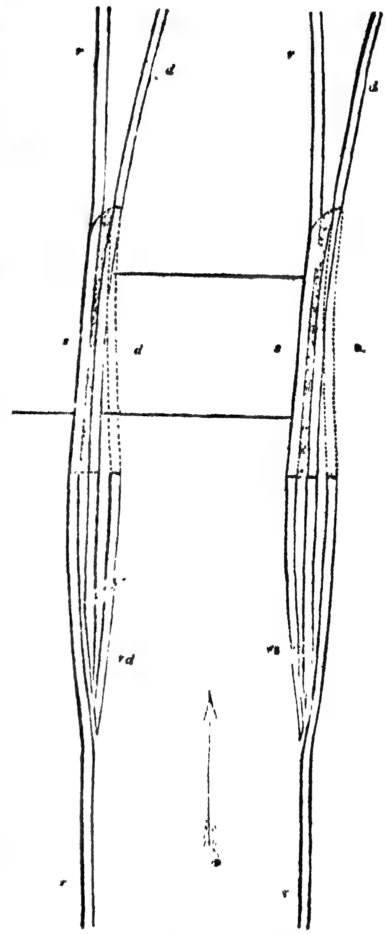
Fig. 4.

When the rail is in its place, a piece of straight grained oak, K, is driven into the key-way, and then folding wedges, W, with claw heads, are driven both sides into the oaken key; thus, the wood becomes violently compressed, and adapts itself to all the conditions of the rail and chair; and for the joint chairs, it will make no difference what may be the variations or twist in the two rails, as the wooden key will, in every case, adapt itself to circumstances, the wedges are drawn back by a set hammer, when it is necessary to take up a rail; this method will hold the rail much more steadily than either an iron or wooden key solely; the shake or jar produced by the train passing over the rails, will not affect the wedges, and they will always remain tight, particularly if care be taken to drive in the wooden keys, when they are dry, the elasticity also of the timber admits of driving the wedges tight, without breaking the chairs; it is thus clear, that the rails of every railway, of whatever figure they may be, can be secured in this manner without any difficulty; in fact, this method is not only better but much cheaper than that usually adopted.

Fig. 1 is an end view; Fig. 2 a plan; Fig. 3 a plan showing the form of the key-way and key when the wedges are driven; Fig. 4, side view.

CURTIS'S RAILWAY SWITCHES.

The annexed figure show the Switches so arranged, that an engine can never run off the line, under any conditions of the switch being placed wrong; this object is effected by forming the switches double on both sides, and laying down supplementary rails *r d*, *r s*, which correspond respectively with the diagonal and straight bars of the switch. Referring to the engraving, if an engine be coming along the line *r*, in the direction of the arrow, it will pass over the diagonal switch and cross the line; if coming along the line in the reverse way, it will pass over the straight bar of the switch and enter the line by means of the supplementary bars, *r s*; if the switch be made to occupy the space shown by the dotted line, and an engine is coming along the line in the direction of the arrow, it will pass straight along the line, and if coming the reverse way along the diagonal line, it will pass along the diagonal switch *d*, and enter the line by the supplementary bars *r d*.



The improved Switches represented in page 52, in the last Number, have been at work upon the London and Greenwich Railway for more than twelve months; they have never been out of repair, nor failed in a single instance. The London and Birmingham Railway Company are now laying them down at the various stations upon the line.

1, Stafford-street, Bond-street. W. J. CURTIS.

LEVELLING.

In the published account of the Trigonometrical Survey of Great Britain, it is recorded, that the height of the top of the parapet of the north turret of the keep of Dover Castle was found, by levelling, by Lieutenant Hay, of the Royal Engineers, to be 465.8 feet above low water spring tides; and that the ground at Folkstone turnpike, deduced therefrom by computation, from vertical angles observed with Ramsden's then celebrated three feet theodolite, was 569.8 feet. It happened, in the spring of 1836, that Mr. F. W. Simms, in the course of some levelling operations for the South Eastern Railway Company, determined the height of the ground at the edge of the cliff close to Folkstone turnpike, above low water spring tide: the result he arrived at was 565.31, differing 3.49 feet from the above result, published in the "Philosophical Transactions for 1790." This result will appear remarkable to those who understand the nature of levelling by triangulation on a large scale, and the uncertainties unavoidable to such proceedings, arising from the refraction of the atmosphere, &c.; besides all which, the whole difference itself might have been involved in the different low waters taken by the two parties.

YORKSHIRE STONE QUARRY.

By R. D. Chantrell, F.R.I.B.A.

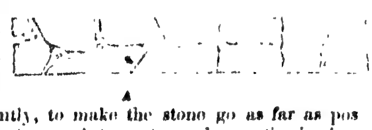
Description of the Mode of working the Springfield Quarry, near Leeds. Paper read before the Royal Institution of British Architects.

The Springfield Quarry is part of a hill, on the north-west side of Leeds, called Woodhouse Ridge. This quarry facing the south-east on the slope, or declivity of the hill, the general dip of the stone is S.S.E. in all the quarries in the neighbourhood of Leeds.

On breaking into the ground the soil varies from 1 to 2 feet in depth; below this is about 4 feet of marl and earth, mixed with small laminated fragments of stone; and at a depth varying from 5 to 7 feet from the surface, is the first bed of stone called rag; this is a coarse tough stone, rising in large layers from 6 to 9 inches thick, is raised by the lever, and to the sizes required for the first course or footings of buildings. In ordinary buildings it is customary to bed a course of this stone in mortar, about a foot broader than the walls; in lofty buildings two courses are laid, the joints crossed, and the two courses bedded solid upon each other in mortar, the lower course being broader than the one laid upon it. The method of cutting this stone into sizes is by what the quarrymen call "nicking." A line is drawn across the stone with a chisel lightly struck by a mallet; when this is done, the workmen strike on the joint with an iron mallet or hammer, extending the strokes from one end of the nick to the other, when the stone breaks vertically to the size marked. This mode applies also to the flag stone, which is usually the third bed or stratum. This is sold in the quarry at 6*d.* per foot cube.

Below the rag is the block stone, and for common walls (No. 1), and usually called wall stone. This may be separated in layers from 5 to 10 inches in thickness, is broken in random sizes, so as to form beds of 7 to 9 inches, and in lengths of 18 to 30 inches. The common walls, called double walls, are laid as Fig. 1; and the middle part is filled in with cuttings, called fillings, of which a sufficient quantity accumulates in the course of dressing the wall stones to suit the face of the piers; the joints of this work are crossed, and in every square yard of face a through or bond stone is introduced to bind the work together, as shown in Fig. 2.

Fig. 1.



The Yorkshire workmen frequently, to make the stone go as far as possible, will bring the stones nearly to a point as at A, when notice is given them of such defect; if not attended to, the architect should direct his clerk of the works to take off the point, as the work is not considered good if the joint is less than $3\frac{1}{2}$ inches.

The wall stones are usually dressed with a broad hammer, and have the appearance of rough tooling. This is called hammer dressing, and will vary from 3*d.* to 5*d.* per foot on the face beyond the cost of the material and walling. The specimen, No. 1, is of the best kind of hammer dressing.

The side on which it is written is termed bosting; this is done with a chisel, and is the first process from the rough stone after delivered from the quarry, in which state the protuberances are struck off only with a dressing hammer. Tooling is also practised upon wall stones, when they cost as much as common hewing or tooled work, 5*d.* to 7*d.* per foot for labour only. (At these prices the labour is understood to be at 4*s.* per day for masons, and 3*s.* for labourers, exclusive of master's profit, which in Yorkshire is 8*d.* for men, and 6*d.* per day for labourers.)

In Yorkshire the workmen calculate all wall-stone work by the rod of 7 yards, or 63 superficial feet. At a distance of one mile from the quarries in Leeds this sort of work is calculated to be completed, the contractor finding lime and sand stone, and carriage of materials, at from 30*s.* to 31*s.* 6*d.* per rod, or 6*d.* per foot, measuring the face of the wall.

This stone requires generally to be struck over or dressed on the beds, there being sometimes irregularities on them. In the seams a quantity of oxide of iron is found, and also mica, which is the case with all the stone of these quarries, and by which means, even in the ashler, the difference between the face and the bed is very perceptible. The block, or wall stone seam, is in this quarry about 10 or 11 feet thick, and the beds vary in thickness.

Beneath this is the laminated or flag bed, which is slaty, still more compact (No. 2). The beds are from $1\frac{1}{4}$ to 4 inches thick; $1\frac{1}{4}$ to $2\frac{1}{2}$ form the common paving, which is sold at the quarry at about 15*d.* per square yard. The wall stone is about 160 lbs. to the cube foot; the flag about 160 lbs. The lower bed of these is the ashlor (marked as such); this is about 148 lbs. to 152 lbs. to the cube foot, and is separated from the large block (or as is technically called "post") by wedges. The workmen cuts with the common wood mallet and short chisel holes at about 6 inches asunder, in the form of the wedges, of which a number are put in on the surface of the stone, and with long handled iron mauls the men strike each wedge inclusively the whole length of the piece to be separated, and endwise the same, the body varying from 10 inches to 14. When the stone is broken, which is almost invariably at right angles to the surface, it is separated on the bed by a large iron crowbar or gavelock, and this is either lewised or chained, and raised by the large crane or "gin," which is usually constructed to raise 14 or 15 tons. The wall stones are raised in cases or boxes open at the end, large enough to raise two or three tons.

In the quarry adjoining to this, there is a bed of large landings, extending near 70 feet in length, and 20 feet thick, which appear nearly level; the separate beds are very distinct, varying from 6 to 14 inches, and are solid as the ashler.

There is stone of the same description alternating to a depth of 50 feet from the surface, and it is the intention of S. T. W. Gawthorp, Esq. of Wakefield, the proprietor, to work it to the full depth, when I will transmit an account, with a section of the quarry, for the information of our Brethren of the Institute.

I shall send also some communication relative to the Grit-stone Quarries, from the materials of which I have erected several public buildings.

LITHOCHROMY.

Extract of a Letter from L. ve Kleuzé, of Munich, dated June 2, 1837, read before the Royal Institute of British Architects.

"I now send you the drawing of the peripteral temple executed by me in Munich Park, which, to the best of my knowledge, constitutes the first example of *lithochromy* in the present day. The stone is calcareous, very hard, of a yellowish white, and almost marble. The site is on a hill, in the midst of very lofty trees, which do not, however, reach midway the columns. The interior forms a semi-circular vault, caissoned, and likewise painted. The ground of the caissons (φατνοματα) is alternately red and green, and the ornaments of a ramified pattern are painted white upon these grounds. I say nothing about the exterior, because the drawing explains it in all its parts.

"The roof is covered with red coloured copper; the ornament above is of white shining metal, partly grounded with bright colours. The whole of these paintings and grounds is executed in the encaustic manner. I cannot tell you how justly the execution of this little monument increases and strengthens my conviction that *there is no classical architecture complete without the concurrence of colour*, and that such ornament forms an integral and adherent part. The non-employment places a monument in the category of a landscape drawing in Indian ink, or in bistre, opposite to one of Claude Lorraine's. Thank Heaven! this conviction is gaining ground considerably with us; I have already had occasion to construct a great polychrome edifice, a post-office. I am at the present time erecting a private mansion of the same kind; and thus this fine taste of antiquity is continually spreading.

"Your pit coal is, indeed, a terrible enemy to *lithochromy;* and you will, perhaps, *do right on that account alone* to keep to the English manner of building of the middle ages, which I was highly pleased with, and which I prefer in every respect on the score of beauty to the Germanic manner of the present day.

"I should fail were I to attempt to speak in general of the agreeable impression that I retain of your fine and great country, of what I saw there, and of the reception that I met with. Unfortunately, it has crossed my imagination like a beautiful dream, but the remembrance will never be obliterated from my heart nor from my mind.

"I congratulate the Institute upon the charter which his Majesty has been pleased to grant. It was certainly well advised to give an official character to a body that has already given proofs of what it will one day achieve, in the first volume of its memoirs, which I have read with great satisfaction.

"L. VE KLEUZE."

PARIS.

Extract from a Letter of M. Guenepin, dated November, 1837, to Thomas L. Donaldson, Esq., *Fellow and Honorary Secretary, R.I.B.A.*

"Our museum at Paris increases in size daily; the opening of some parts, which will complete the whole of the court of the Louvre, will soon take place. They will consist of the apartments of Henry III. and Henry IV., entirely restored in their primitive style; the 900 pictures of the Spanish school lately purchased; and also a numerous exhibition of original drawings of the great masters, which have been hitherto hidden from view in portfolios.

I must also tell you, that there has been erected in the half of the gallery of the Museum, which you well know on the side facing the river, a gallery in wood work, eighteen feet wide; this temporary gallery was first intended for a fête, which the king intended to give to the city of Paris, and to which 4,000 persons were to be invited. He also proposed to give to the Corporation a dinner, in return for that to which he had been invited some time previously at the Hôtel de Ville. These arrangements, however, having been relinquished, they were unwilling that the expenses incurred for this gallery should be lost, and there has been exhibited a long series of curious tapestries, comprising ancient royal chateaux, from the Gobelins and other manufactories; amongst them were some very remarkable ones, which dated farther back than Francis I.; several of them from the designs of Raphael, &c.; and you may judge somewhat of their number on hearing, that they occupied, on two sides, the whole length of the temporary gallery, which covers half the space between the Louvre and the Tuilleries. Great works and immense demolitions are in progress to enlarge the Hôtel de Ville, and to add thereto two wings, which will double its extent. The design is happily conceived, and this building will preserve the original character in which it was constructed.

The style of the transition between the Gothic and the revival, the embellishment of the Place Louis XV., and the Champs Elysées, are now going on. The Church of the Madonna de Loretto, constructed by Le Bas, our colleague, is quite completed, and open for public worship; it is entirely covered with paintings, and the ceiling is richly decorated with gilt coffers. This style of church, which is in imitation of the small Basilicas at Rome, was quite unknown at Paris, and although it does not quite conform with our religious habits in richness of decoration, contrasts strongly with the naked interiors of our churches; nevertheless, it has met with great success.

ON ARCHITECTURAL NOTATION.

By T. L. Donaldson, Esq., Fellow and Honorary Secretary Royal Institute of British Architects.

SHEWING THE DIFFERENT SYSTEMS ADOPTED BY ENGLISH WRITERS ON ARCHITECTURE, WITH THE SUGGESTION OF AN UNIFORM SYSTEM FOR GENERAL ADOPTION.

Paper read before the Royal Institute of British Architects.

A General Table showing the various modes of Notation used by different Writers on Architecture.

WRITERS ON GREEK ARCHITECTURE.	
1' . 2'' . 5	Stuart; Revett; Wilkins in one part of his Magna Grecia.
1′ . 2″ . 5	Wilkins; Deering in his Plan of the Temple of Ceres at Eleusis; Cockerell.
1 . 2 . 5	Bedford; Deering in the other Illustrations of the Inedited Antiquities of Attica.
1° . 2′ . 5″	Donaldson; Railton; Jenkins.
1 , 2 5'	Kinnaird.
WRITERS ON ROMAN ARCHITECTURE.	
1 ——— 2½	Adam in his Ruins at Spalatro.

1ft. 2½	Britton.
1 .. 2½	Mackenzie and Pugin; Britton.
1′ „ 2″½	A. W. Pugin, generally in Ancient Edifices of England.
1ft. 2″½	Walker.
1 , 2½	Caveler.

This is a subject to which few of our professional authors appear to have paid any attention; yet when we consider, that among a class of men professing an important branch of science—men supposed to be liberally educated, and in whose studies mathematics should form a prominent share—it seems extraordinary that nineteen authors from the time of Stuart to the present period have thirteen different ways of notation. This may be thought to be almost impossible. It will therefore be necessary, in the first instance, to establish this fact, as its absurdity may make you concur in advocating the necessity of one universal system of notation to be adopted henceforth by all English architects who may write on the Art.

We will commence with the authors who have written on Greek architecture, taking them in chronological order. Stuart and Revett stand at the head of this list, and both adopted the same method of notation. Thus, to express one foot two inches and a half, they wrote the numerals thus, 1' . 2'' . 5, placing a grave accent over the first figure representing the feet, two accents over the inches, but omitting any over the third figure, which was expressed decimally by a .5 as five-tenths, or half the inch. In addition there was a dot between each figure to render them still more distinct; it was, in fact, necessary before the five to make it express five tenths.

I would here make a remark, which, although not immediately pertinent to our subject, is not uninteresting to an architect. Every one is aware, that as all the dimensions of the orders in Stuart's "Athens" are given from the centre of the column, of course it was necessary to calculate every dimension, as, with the exception of the diameter, the various projections of the capital and entablature could not be taken from that imaginary line the centre, or axis of the column. Cockerell, Deering, and Bedford have also followed this system of calculating the projections of the different parts of the orders from an imaginary vertical axis of the column. Thus, not one of the dimensions is a pure dimension taken at once; and in fact all are false, for the axis of no column, it has since been proved, is vertical, which Stuart and Revett assumed it to be. But all the original dimensions taken by Stuart, I am assured by unquestionable authority, were taken in eighths, twelfths, or any parts of an inch which happened to be on the ruler with which he and his companions were measuring, being afterwards reduced, by calculation, to one uniform standard.

Mr. Wilkins follows next in chronological order, who, in some plates of his work on Magna Grecia, follows the system of Stuart and Revett; in other parts of the same work, he omits the accents altogether, and in his most recent work of "Prolusiones Architectonicæ," has adopted the acute accent instead of the grave, thus, 1′ . 2″ . 5, which method of notation is adopted also by Mr. Cockerell, in his illustrations of the Temple of Jupiter Olympius at Agrigentum, forming part of the supplementary volume to Stuart's "Athens."

The architects who furnished the illustrations to the "Inedited Antiquities of Attica," Messrs. Deering and Bedford, have different methods of expression, Mr. Deering following the latter mode of Mr. Wilkins in the plates of the Temple of Ceres at Eleusis; but in the other parts, his notation being the same as that of Mr. Bedford, omitting the accents altogether, and only using the intermediate dot, thus, 1 . 2 . 5.

The three next authors, who will be quoted in their chronological order as writers on Greek architecture, are myself, and Messrs. Jenkins and Railton, contributors to the supplementary volume of Stuart's "Athens," all of whom follow the same manner of notation, which is a new one, thus making a material alteration from the old method, 0° . 2′ . 5″, and being the first attempt to follow the system adopted in astronomy.

Mr. Kinnaird, the fifth contributor to the same work, adopts a different manner, placing the grave accent only over the decimal, thus, 1 . 2 . 5', with a single dot between each figure. Thus the twelve writers above-named have five distinct methods of notation.

We now come to the authors who have published works on Roman architecture, of whom there are only two in England who have given the dimensions of those ancient edifices in feet and inches; they are Adam, and Taylor and Cresy.

The volume of Adam upon the Palace of Diocletian at Spalatro, has the lengths thus noted, 1 —— 2½, the feet being separated from the inches by a long line; Messrs. Taylor and Cresy express the same quantity thus, 1 „ 2 ′5. There being no accent over the feet, which are divided from the inches by two strokes, and an accent marks the decimal.

We have several writers on Gothic architecture, whose valuable volumes afford as rich a variety of notation as the preceding; for there are as many methods as authors, but all agree in not using the decimal division of the inch, as shown in the table.

It is true, that this want of uniformity among the various architectural writers is not likely to lead to any material errors, as the great disproportion in the foot and inches suggests immediately the meaning of the peculiar notation; but it may be puzzling to the foreigner, who may consult their works, and who might not know whether the chain, the yard, or the foot were meant for the primary quantity. It is however ridiculous, evinces a want of precision and of uniformity of practice, as also an absence of scientific method, hurtful to their reputation as men of science.

Mr. Babbage, in his article on Notation, in the XVth volume of Brewster's "Edinburgh Encyclopædia," remarks, that "the great object of all notation is to convey to the mind, as speedily as possible, a complete idea of the operations which are to be or have been executed:" this is in reference to algebraic notation; but it becomes much more simplified, when we recollect that in architecture instead of operations we have merely to indicate lengths.

The same author lays down a system of laws for the adoption of symbols, which, by a slight alteration, is equally applicable to architectural as to algebraic notation.

"1. Since every thing is exhibited to the eye, the more compact and condensed the symbols are, the more readily will they be caught as it were at a glance.

"2. All signs of notation should be as simple in character and as few in number as the nature of the operations will admit.

"3. We must adhere to one notation for one thing.

"4. Analogy ought to be our guide in the formation of all new notations."

Your attention having been called to the variety of notation which exists in our professional writers, it may be expected that a system should be proposed, which shall unite the requisites contained in Mr. Babbage's rules. In the first place, then, let the feet and inches be separated by two strokes, in the same manner as in our monetary system the pounds are divided from the shillings and the shillings from the pence. This may be assumed to be unexceptionable, as all the writers above quoted agree that the division between the feet and inches should be marked by a line, a dot, or two strokes; besides which, the strokes more effectually divide the figures and render less probable any errors of the press. The parts of an inch, I propose, should be expressed decimally by a single dot, as all the writers on Greek architecture have adopted it without exception.

The next question to be settled, is as to the symbols which should indicate the quantities to which the numerals or figures act as co-efficients; that is, the feet, inches, and tenths; these are necessary in the event of only feet and inches being figured, or inches and tenths, in order to show at a glance the quantities intended to be expressed. It is proposed therefore to follow up the theory of analogy, by adopting the system of astronomers into their distinction of degrees, minutes, and seconds, and appropriating a small circle ° to the feet as the primary quantity, the single stroke or acute accent for the inches, and the double stroke for the tenths, thus, 1° „ 2′ . 5″; the acute (′) is to be preferred to the grave (') accent, as having the same inclination with the handwriting, and being consequently more readily written. It might be said that the double strokes over the decimal parts of the inch are rendered unnecessary by the adoption of the dot below; but it is better, perhaps, to retain them both, as rendering the system more complete, and the different quantities perhaps more distinct. The adoption of the ° from astronomical authors could never cause any confusion, for we never measure temples or even cities by degrees of miles, and the whole system would be rendered at once clear to the reader, if the scale were always placed at the bottom of the plate, and the different divisions carefully marked thereon.

This is the system which I have of late adopted in my own publications, and I have found no difficulty to arise from its use.

There are some among us, perhaps, who may not like innovations upon old practices, and who may possibly think themselves fettered by any one system being slavishly followed; that where all have been so free hitherto, all should remain unshackled from such generalizations. But surely we need not be withheld, by fear of innovation, from introducing a system which may rescue us from the reproach of want of scientific accuracy and precision of expression. Where all, even the highest names, have so differed, surely it is not unreasonable to suggest a uniformity of practice, in this respect, by the adoption of a system borrowed from a sister science, and which, it is hoped, practice will prove to be free from obscurity and difficulty. If it have not reason on its side, that will be a sufficient cause for its rejection.

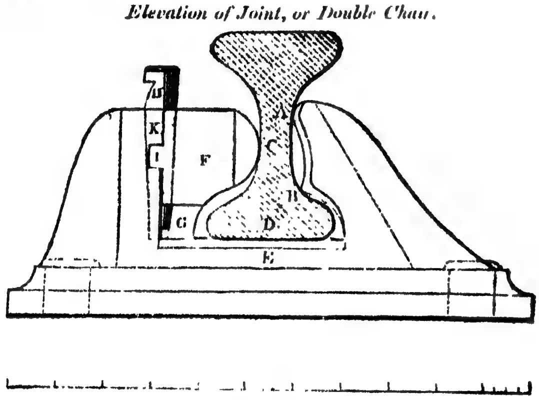
In the preceding remarks, allusion has been made merely to this system as to be adopted by writers on architecture. In making out working drawings for workmen to execute, the practical architect will, of course, adopt the method most consistent with his usual practice; and in cases where country workmen are employed, too great clearness and precision cannot be adopted; hence it is frequently necessary to express the feet and inches by letters, ft., in., in order to avoid those misconceptions to which workmen are liable, in respect to figures. But if the mode above recommended were generally in use, I see no difficulty that could arise, with the exception that I should re-

commend the parts of the inch to be expressed by ¼, ½, or ¾, and the intermediate divisions in eighths, as the rules commonly in use are so divided: the quantity above adopted would, therefore, stand thus—1°,,2'¼, and the double stroke be omitted, as unnecessary.

MR. BUCK'S CHAIRS FOR PARALLEL I RAILS.

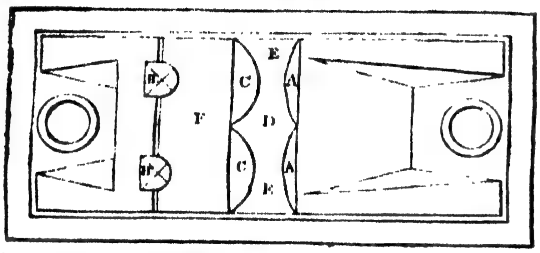
In the first place, it is necessary to observe, that however strong a rail may be, a certain amount of deflection between the points of support must result from the gravity of the passing load; therefore, in order that no motion may be communicated to the chair (which is essential to the maintenance of the road in good order), the connexion between the rail and chair must be such as to allow of the libratory motion arising from deflection, the rail being nevertheless firmly fixed upon its seat, incapable of rising therefrom, and prevented from lateral movement; at the same time it should be free to move longitudinally as much as the expansion and contraction of its length from variation of temperature may demand. To attain these ends is the object of Mr. Buck's contrivance.

Elevation of Joint, or Double Chair.



Scale of Inches.

Plan of Double Chair, the Rail being omitted.



The above engravings contain a plan and elevation of a "joint, or double chair." The same letters refer to the same parts in both figures. In the elevation of the chair, the rail is sectionally represented in its place; in the plan it is omitted. The seat of the rail in the chair at D is convex, being $\frac{1}{16}$ of an inch higher than at E E; this form permits the libratory motion of the rail on its seat at or near D, but is not peculiar to the chair I am now describing; it has been adopted in others, and is sometimes called "*cat backed.*"

That side of the chair which is next to the flanges of the wheels has contact with the rail at only two points, A and B; these are blunt points, produced by the side of the chair being formed into spheroidal knobs; A is in contact with the vertical rib of the rail, and B with the superior part of the lower web, where a tangent to its curved surface forms an angle of 45 with the vertical. On the outer side of the chair the rail is confined to its place by a cast-iron "*chock,*" or *filling-in piece*, F; that part of it next the rail is also made in a spheroidal form, and touches in a point only at C, about midway between A and B.

This chock has a step or foot G, resting on the seat of the chair, with a fillet I fitted into a corresponding groove in the chair, and the chock is wedged against the rail by means of the wrought iron key H; this key is passed into a mortice, one half of which is in the chock, and the other half in the chair, by which the key and chock are secured in their relative positions.

The mode of laying the rails in these chairs is as follows:—The blocks or sleepers, with the chairs affixed thereto, being previously laid in their places, the rails are dropped into the chairs (the width between A and K being sufficient for that purpose), and the chocks are then inserted horizontally, and wedged up by means of the keys H.

The effect produced by keying the chocks moderately tight against the rail at C, is to force the rail against the points A and B, and thereby, at the same time, down upon its seat at D, by the action of the point B, on the inclined surface of the rail in contact therewith. Now, it must be obvious, that so long as the key remains in its place, the rail is completely fixed laterally and vertically, and that it will be easily moved longitudinally when contracted or expanded by difference of temperature; also, that the libration of the rail, occasioned by deflection, will produce only a very minute rubbing at the points A, B, and C.

A notch is made on the outer side of the head of each key for the purpose of extracting it by the application of a lever or pinch-bar.

The joint, or *double* chair, differs from the intermediate or *single* chair, in being so much wider as to receive a double chock, with two knobs o each of which is keyed against the side of the end of one of the two which meet in the chair, the chock having two keys for that pur It may be objected that there is a chance of the keys getting lo and jumping out of their mortices when a train may be passing high velocity; the most satisfactory answer to which is, that upon the Lon and Birmingham Railway, about four hundred yards in length have been by way of experiment with these chairs, over which the passenger trains been running at velocities generally exceeding thirty miles an hour, with the least appearance of the keys working out; but, on the contrary, mos them have rusted fast into their places, and the points of contact have beco smooth, and a little brightened by the libratory motion, which is an indica that these chairs fully answer the purpose intended.

In a rail weighing sixty-five pounds per yard, with four feet bearings, space moved through at each deflection by that part of the rail which is contact with the point C, is $\frac{3}{1000}$ of an inch.

These chairs are designed as a substitute for those now very genera adopted for similar rails, in which wood keys, or filling-in pieces, from 5 to inches long, are used, and to which there are the following objections:—

First.—The keys, or filling-in pieces of wood, are liable to shrink in weather, and consequently to become loose and get out of their place

Second.—Instead of keeping the rails down upon the seat, they lift the from it, and a blow is produced by the passing load forcing the r down upon the seat of the chair.

Third.—In the joint chairs, one end of the key or filling-in piece is press down by the deflection of the rail, and at the same time the other end it is elevated, whereby the but-end of the contiguous rail, to which t wheel is advancing, is raised above the level of that upon which t wheel is at the instant pressing, and a shock is produced by the whe coming into contact with the but-end thus raised. This effect produced when there is sufficient room in the chair for the play of t rail; but when the rail tightly fills the chair, a rocking motion communicated to the chair, and by the chair to the block, or sleepe by which the road is rapidly put out of order.

Fourth.—The wood filling in pieces will prove less durable than the cast-ir chocks, even supposing the wood to be Kyanized."

RAILWAY CHAIRS.

SIR,—As Railway Engineering is now attracting a great portion of th public attention, perhaps the following simple suggestion may not be though unworthy of the notice of those engaged in facilitating the operations of thi popular branch of science. Your's, &c. C. L. O.

Experience having proved the importance of firmly fixing the rails into th chairs in all edge railways, and this operation being attended with some diffi culty, the following plan is respectfully submitted to the consideration o engineers, &c.

Fig. 1.

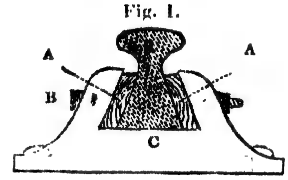


Fig. 2.

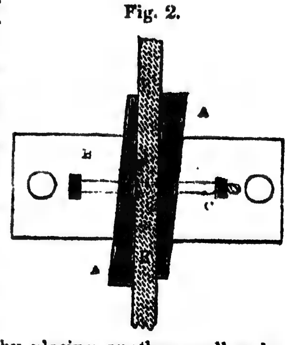

Fig. 1 represents the section, and Fig. 2 the plan, of an edge rail R, the flange of which is of a dovetailed form, with an opening in the chair C of a similar shape, only much larger; between the rail and the chair are two wedges A A of compressed oak, or other hard wood, drove in the reverse way to each other, as shown in the plan, Fig. 2. B is a screw-bolt, passing through both sides of the chair, through both wedges and rail, and screwed upon the other side of the chair, thereby preventing the sides of the chair from being forced too far apart by the wedges. The wedges might first be drove tolerably tight, and a hole bored through them carefully, to admit the bolt, which being screwed fast in, would compress the rail so effectually, as to entirely prevent looseness or shaking; the hole in the rail should be made larger than the bolt, to admit of its being accurately adjusted. By this method the rails might be adjusted with the greatest nicety, either to the right or left, in case the chairs were not very accurately fixed upon the sleepers, &c., as the wedges on either side could be increased or reduced in thickness as found requisite; the rails might likewise be slightly raised or lowered, by placing another small wedge underneath, either of wood or iron; and should the wedges at any time work loose, they might easily be replaced by fresh ones. Another advantage attending the adoption of this plan would be, that the wedges would yield slightly to the pressure caused by the expansion of the iron, and the whole might at any time be lightened by another turn of the screw-bolt; it must however be obvious, that the chairs must be of wrought-iron.

In the first instance, this plan might be attended with an increase of expense, but the advantages would, I think, greatly counterbalance it.

[In courtesy to our correspondent, we insert his letter and plan, which is ingenious, and have made such alterations as free it from those technical objections which would have otherwise been attached to it.—ED.]

PORT OF IPSWICH.

The importance of the town of Ipswich, in a commercial point of view, is sufficiently obvious to those who will look at its geographical situation, with the river Orwell navigable from the sea to the town, and of sufficient depth of water for vessels drawing 16 feet to approach within a short distance. The trade and commerce of the town is both extensive and prosperous, and, as a natural result, is on the increase. The merchants and influential persons of this place, taking the example of those of Liverpool, Bristol, and other flourishing ports, resolved upon examining if it were possible to render their port better suited to a growing commerce than nature had left it, and by affording greater facilities to trade, endeavour to win more of it to their market. The principle aimed at was the accommodation of a larger class of vessels than had hitherto been able to enter the port, so that the port might be adapted to a foreign trade, and to give as much facility to the shipping generally as the means would afford. The subject was under discussion by the principal inhabitants of the town for some time, and at length, resolving to call in professional assistance, they applied to H. R. Palmer, Esq., to examine and report upon the capabilities of the river to be converted into a port for the trading of vessels of 400 tons burthen. That gentleman made the necessary surveys and examinations in the following summer (1836), and having laid a plan before the proper authorities, which was approved of, an Act of Parliament was obtained during the last session to carry it into effect. From this plan it appears, that by making a new channel for the waters of the river Gipping, a wet dock can be constructed, by throwing an embankment across the present channel, which shall contain an area of 33 acres, and to have constantly 17 feet depth of water, which will be sufficient for the average build of vessels of 400 tons, although, from the difference in their form or build, many vessels of that tonnage draw considerably more. Mr. Palmer, in the last page of his Report to the authorities of Ipswich, has given a list of twenty-three vessels which have entered St. Katherine Docks, London, whose average registered burthen was 403 tons, and whose average draught of water was 16 feet 5½ inches.

The penning up that part of the river Orwell which is contiguous to the town, will form a capacious floating dock immediately connected with the numerous mercantile establishments already formed upon the banks, and the new channel, which is to be formed for the river in lieu of that which is to be enclosed, will prevent the tidal waters being impeded, and enable the land waters to move as freely as before. It is also proposed to construct a continuous quay around the basin or dock, in front of the present partially dilapidated wharfs, which shall be at least 30 feet in width. This will admit of a sewer being laid under its surface, having such a magnitude as to receive the drainage of the town, and this being continued to the external side of the embankment, will enable the soil to be freely carried off, without any deposit being formed in the dock.

The entrance lock is to be 140 feet long, and 30 feet wide, and the dock, as before observed, will contain 33 acres, being three acres more than the whole area of the London Docks, and exceeding by more than twenty acres the area of water in St. Katherine's Docks, in London.

The following is a copy of the estimate of the expenses, appended by Mr. Palmer to his Report:—

	£
Earthwork for the dock, the new channel for the river, and the deepening the present channel	27,000
Masonry, brickwork, timber, and iron-work, in the lock and its wing walls, including two pair of gates, and the machinery for working them—mooring posts and rings	6,500
Quay wall along the face of the town, from Peter's Dock to the commencement of Mr. Cobbould's Ouze, stone coping, oak fenders, sheet piling, concrete and puddling	14,000
Forming a quay 30 feet wide—a sewer, extending from Peter's Dock to the outside of the lower embankment, having man-holes, tide flaps, and gratings	3,500
	51,000
Contingencies, 10 per cent.	5,100
	56,100
Excavating channel near Downham Reach, to avoid the bend in the river, say (in the absence of more accurate data)	2,000
	£58,100

We understand that Mr. Palmer is now about to commence the above important works, the contract drawings being complete, and the preliminary arrangements for the purchase of land, compensation, &c., being in a forward state.

NEW CARRIAGES FOR THE GREAT WESTERN RAILWAY.

We have been favoured with a view of the new bodies building for the carriages of this railway by Mr. Davis, of Wigmore-street, and were highly gratified with their excellent build and accommodation; they are 12 in number, 8 of them being 18 feet long and 8 feet wide, and the remainder 21 feet long and 8 feet wide. They are fitted up in an elegant style, and have the appearance and almost the accommodation of the saloon of a steam-packet. The 18-feet carriages have 9 separate seats, resembling sofas; 5 on one side and 4 on the other, for 2 passengers each, separated by scroll-cut standards; the seats and backs are stuffed with horse-hair, and covered with handsome mohair velvet, and underneath is ample room for the passengers' luggage; the windows are over the back of the seats, and occupy the whole width in one sheet of plate glass, and furnished with spring silk blinds; the floor is covered with Brussels carpeting. The centre part of the roof or ceiling is raised to give headway, and is sufficiently high for a tall person to walk upright; on each side of the raised ceiling are copper gauze wire panels for ventilation, regulated by wood slides or shutters. At each end of the carriage is a small table for the accommodation of the passengers; this table is ingeniously contrived to turn upon its edge, when not in use, by means of a hinge-joint and double brackets turning upon two iron standards fixed to the floor. A lamp is provided at each end. No expense has been spared to render them worthy the name of first class carriages, and much credit is due to Mr. Davis for their excellent workmanship; it is estimated that they will cost 400*l*. each for the bodies only, exclusive of the carriages, which are being made by the engineers. The larger or 21 feet carriages are divided into 3 compartments, and fitted up similar to the others, except that the centre compartment will contain accommodation for 10 passengers, and those at the ends for 4 more each, forming small cabins, particularly suitable for families wishing to be by themselves.

THE NAVAL ARSENAL AT ALEXANDRIA.

When you enter the Arsenal of Alexandria, and behold a colossal establishment, with massive and handsome buildings, extending almost farther than the eye can reach—an establishment which is nowise inferior to many similar ones in Europe, and, in many points, is even superior to them; when you see the large ships which are there building, and immense magazines, filled with stores of every kind, sufficient completely to equip many others—and when you are then told, that only eight years ago the waves of the sea rolled over this very spot, and that the whole magnificent fleet which now fills the harbour was constructed in this arsenal, it really appears like a dream. If we further consider that these miracles of activity and sagacity have been performed by the inflexible *will* of a single man, in a land of the most complete barbarism, where, hands and arms excepted, there was scarcely one of all the requisites for such an undertaking, the astonishment of the spectator is doubled, and he is tempted to take literally the declaration in the Gospel, that faith is able to remove mountains. Has any European sovereign performed any thing similar in an equal space of time? I know of none—nay, had I not seen it with my own eyes, I should have believed such an undertaking to be wholly impracticable. Notwithstanding this, the bold spirit of Mehemet Ali does not yet rest, and he is now engaged in an undertaking almost equally gigantic, namely, to gain from the sea, where the bottom is covered with mud, to the depth of nearly a hundred feet, a basin capacious enough to contain the whole fleet, and from which the water may be drawn off at pleasure. The vast coffers which are building in the dock yard for the purpose of being sunk, are nearly as large as ships of the line. The possibility of success is almost universally doubted—Mehemet Ali alone does not doubt, for, like Napoleon, he knows no such word as "impossible." One of the foreign Consuls said, to dissuade him, "Your Highness throws your money into the sea." "Allah Kherim," replied the Viceroy good humouredly, "Why, I have been doing nothing else for many years past." Of course I have no intention of describing the arsenal in detail, as such establishments are sufficiently known, and all must, more or less, resemble each other. I mention only what particularly struck me; for instance, the admirable rope manufactory, which is equal in extent to that of Toulon, and is superior to it in arrangement. Here I saw, for the first time, the ingenious machine, invented by a Frenchman, for twisting the cables: the work produced appeared to me to be equal to the best English manufacture. In order and scrupulous cleanliness, as well in the magazines as in the workshops, the French arsenals are decidedly inferior to this. It is an excellent arrangement that, when the day's work is done, the workmen are obliged, before they leave the place, to hang up on the walls and pillars all the instruments that have been used during the day, in elegant figures, as is usually done for ornament in armouries. The advantage of this is, that the instrument cannot be mislaid or lost, and the theft is discovered at once. For this and many other judicious regulations, the arsenal is indebted to the unceasing care of General Besson, the worthy successor of the founder Cerisy, whose name will be held in eternal remembrance in Egypt. With the exception of the delicate nautical and mathematical instruments, very few articles of European manufacture are seen in the magazines. Arms, paper, clothing, linen, leather goods, cloth (partly of cotton), are all Egyptian. Three ships of the line were building in docks, which, in this climate, it is not necessary to roof over. In the lower walls, consisting of large hewn stones, several antique granite pillars and Egyptian figures are introduced, not without taste: this is unimportant; but what affords great pleasure is the solidity, the perfect order, the extreme cleanliness which characterize the whole, and charm the stranger, to whichever side he turns.—*Semilasso (Prince Puckler Muskau) in Egypt.*

ON THE EXPANSIBILITY OF THE DIFFERENT KINDS OF STONE.

Mr. Alex. J. Adie, Civil Engineer, has performed an extensive series of experiments upon different kinds of stone, as well as upon iron and upon brick, porcelain, and other artificial substances. The instrument employed was a pyrometer of a simple construction, capable of determining quantities not greater than $\frac{1}{30000}$ of an inch. The length of the substances generally employed was 23 inches. The general result of these experiments is, that the ordinary building materials of stone expand but very little differently from cast-iron, and that, consequently, the mixture of those materials in edifices is not injurious to their durability. The experiments from which the expansibility of the substances was numerically determined, were made between the limits of ordinary atmospheric temperature and that of 212°,

steam being introduced for that purpose between the double casing of the instrument.

The following results were obtained for the fractional expansion of the length, for a change of temperature of 180° Fahr.

Table of the expansion of Stone, &c.

	Decimal of length for 180° Fahr.
1. Roman cement	.0014349
2. Sicilian white marble	.00110411
3. Carrara marble	.0006539
4. Sandstone from the Liver Rock of Craigleith Quarry	.0011743
5. Cast iron from a rod cut from a bar cast 2 inches square	.00114676
6. Cast iron from a rod cast half an inch square	.001102166
7. Slate from Penrhyn Quarry, Wales	.0010376
8. Peterhead red granite	.0008968
9. Arbroath pavement	.0008985
10. Caithness pavement	.0008947
11. Greenstone from Ratho	.0008089
12. Aberdeen gray granite	.00078943

15. Stalk of a Dutch tobacco pipe	.0004573
16. Round rod of Wedgewood ware (11 inches long)	.00045294
17. Black marble from Galway, Ireland	.00044519

Trans. of Roy. Soc. Edin.

DINNER AND PRESENTATION OF A PIECE OF PLATE TO ROBERT STEPHENSON, ESQ., ENGINEER-IN-CHIEF OF THE LONDON AND BIRMINGHAM RAILWAY.

On Saturday, the 23rd ultimo, a Dinner was given at the Dun Cow Inn, Dunchurch, on the occasion of presenting a splendid Piece of Plate to Robert Stephenson, Esq., as a token of the high respect and esteem in which he was held by the Members of the Engineering Department who were employed in the execution of the works on the London and Birmingham Railway, on the eve of their gradual separation, as the works are being completed.

About fifty-five gentlemen sat down to dinner, the whole of them (excepting Mr. Parker of London, and Mr. Carter of Birmingham, Solicitors to the Company) were connected with the Engineering Department of the Railway. Mr. Forster, the Resident Engineer at Coventry, took the chair, supported on his right by Robert Stephenson, Esq., and on his left by George Stephenson, Esq.; Lieut. Lecount, R.N., was the Vice-chairman. After partaking of a most excellent dinner, and the usual preliminary toasts being drunk, the Chairman, in a very eloquent speech of considerable length, presented the Plate, consisting of a Massive Silver Soup Tureen, beautifully mounted with a chased border and ornament in frosted silver, standing on a large Silver Salver corresponding with the Tureen; manufactured at Birmingham, and cost 120 guineas. On the body of the Tureen is the following inscription:—

TO ROBERT STEPHENSON, ESQ.
ENGINEER-IN-CHIEF
OF THE
LONDON AND BIRMINGHAM RAILWAY.
A Tribute of Respect and Esteem from the Members of the ENGINEERING DEPARTMENT, *who were employed under him in the execution of that great Work.*
Presented on the eve of their gradual separation,
DECEMBER 23RD, 1837.

On the opposite side of the Tureen the Names of the Subscribers are inscribed.

After the presentation of the Plate, the Chairman proposed the health of Mr. R. Stephenson, which was responded to enthusiastically by all the gentlemen present.

Mr. Stephenson, whose feelings were completely overpowered by the eloquent speech of the chairman, and the manner in which his health had been drunk, returned thanks in a very forcible and appropriate speech.

The Vice-chairman, in an animated and humorous speech, proposed the health of Mr. George Stephenson, which was drank with tremendous applause.

Mr. George Stephenson, in returning thanks, took occasion to impress on his hearers, the necessity there existed, in all the various branches of Engineering—for *perseverance*; and related an anecdote which occurred during his arduous and difficult execution of the great work, the crossing of Chat Moss, on the Liverpool and Manchester Railway, and which fully bore out his previous remarks. He stated, that after working for weeks and weeks in filling in material to form the road, there did not appear the least sign of their being able to raise the solid embankment one single inch—in short they filled in, and still it did not get any higher; his assistants also began to be doubtful of the success of his scheme. The Directors, too, were alarmed, and began to fear it was a hopeless task; so much so indeed, that a Board meeting was held on Chat Moss!! to decide as to whether Mr. Stephenson should proceed; and they had previously taken opinions of other Engineers, who had reported unfavourably upon the scheme: there is no doubt but that for the immense outlay that would have to be made had the scheme been abandoned and the line taken by another route, that the Directors "*were compelled*" to allow Mr. Stephenson to go on with his plan (who however had never for a moment doubted of his ultimate success). Determined, therefore, to persevere with his original scheme of execution, he ordered the works to proceed as before—and to the surprise of every one connected with the works, in six months from that day a locomotive engine and carriage passed over the very spot with a party of his friends to dine at Manchester. Mr. Stephenson also explained his reasons for the manner in which he had, in spite of adverse opinions, carried the work forward—he considered that a ship floats in water, and that the Moss was more capable of supporting weight than water; and he knew that if he could but once get the material to float it would succeed. How far his efforts were successful has been fully proved, not only to this country, but to the whole world, for that portion of the road which formerly consisted of such materials that not a cow could walk upon it, now forms the *very best part* of the road, and is a proud example of his genius; and the name of *Stephenson* will be known in after ages, as one of our brightest ornaments—as a man of science.

LONDON AND BRIGHTON RAILWAY COMPANY.

ENGINEER'S REPORT.

"*To the Directors of the London and Brighton Railway Company.*

"Gentlemen,—In consequece of your instructions, that I should in the first place take effective measures to have the whole of the enlarged plans and sections taken, to determine upon the exact line of railway, and to report if any improvements could be made on the Main Line of railway between Croydon and Brighton, and also on the Branch Line from Brighton to Shoreham, I beg leave to report to you, that I have been incessantly engaged with my assistants and surveyors, for nearly two months, in prosecuting the surveys, and in the examination of the country in every direction, and having completed the plans and sections on a working scale, it gives me great pleasure to report to you that the improvements of which the line of railway is susceptible can be made within the limits allowed by the powers of the Act of Parliament.

"The only material deviations are at Merstham and Balcombe, where it was desirable to make the tunnels straight; and as the consent of the parties to whom the land belongs has been obtained, these improvements can be effected.

"In consequence of the recommendation of Captain Alderson, of the Royal Engineers, the Parliamentary Committees of the Lords and Commons authorized the substitution of a tunnel at Merstham for open cutting, and the lengthening of the tunnels at Balcombe and Clayton; whereby, and by other improvements which I have made, I have been enabled to reduce the cuttings from 9,251,000 cubic yards of earth work, to 5,867,000 cubic yards, making a saving in cutting of 3,384,000 cubic yards; and by introducing arching in some places instead of continuous embankments, and availing myself of the advantages of the Parliamentary powers, I have reduced the embanking from 4,793,000 cubic yards of earthwork to 3,715,000 cubic yards, making a reduction in the amount of embanking of 1,078,000 cubic yards. The work is, therefore, one of ordinary extent.

"With these improvements, and allowing the most liberal prices for the work, the amount of my estimate for the main line, exclusive of contingencies, is reduced to 706,000*l.*; and allowing 10 per cent. for contingencies (amounting to 70,600*l.*) the total amount of my estimate is 776,600*l.*, 29,372*l* less than the Parliamentary estimate; which saving being added to the 70,000*l.* will give me nearly 15 per cent. for contingencies.

"No material alteration has been, or can be, made on the branch to Shoreham; the cost of this branch, I find on a revised estimate, amounts to 69,800*l.*

"These estimates, of course, do not include the value of the land or buildings.

"In my labours I have had the advantage of the assistance of Mr. Joseph Locke, who has taken great pains to make himself thoroughly acquainted with the whole of the main line and the branch to Shoreham; and has gone over the ground with me, and fully considered every thing that could bear upon the improvements of the line, the manner of execution, and the value of the work; and although I do not exactly agree with him upon the value of every part, we fully agree upon the principle and manner of carrying the work into execution. He will of course report to you his own opinion, as well as present you with the amount of his estimate.

"In conclusion I beg to state—

"That this line of railway is the very best which can be obtained between London and Brighton.

"That there is no necessity for any fresh application to Parliament.

"That the main can be executed for 805,972*l*, and the branch to Shoreham for 69,000*l.*

"That the main line can be completed and opened to the public in three years from the commencement of the work, and the branch to Shoreham in about eighteen months

"And with regard to the often-agitated question of the supposed necessity of cutting chalk with a slope of one to one, instead of the plan I propose to adopt, I have calculated the extra quantity of cutting that the slope of one to one would require, and I find that for both the Merstham and Clayton cuttings, it would only amount to about 1,000,000 of cubic yards extra, the cost of which would not exceed 10,000*l.*, which sum is the additional expense that such an extraordinary expedient would occasion, if resorted to, but I shall prove, in the execution of the work, that it is altogether unnecessary. I am, gentlemen, your most obedient humble Servant,

"*London, 7th Dec.* 1837." "JOHN U. RASTRICK."

"*To the Directors of the London and Brighton Railway Company.*

"Gentlemen,—I have had the honour to receive from your Secretary the following resolution of your Board, dated 31st of October last, namely,—

"'That Mr. Locke be requested to go over the line with Mr. Rastrick, and investigate his plans, sections, and estimates, and report his opinion upon the line, and the improvements that have been made upon it; and the sufficiency of the estimates, and the time in which the line can be completed.'

"In pursuance of this, I have accompanied Mr. Rastrick, with a view of forming an opinion of the merits of the several changes contemplated by him. I have, by this investigation, acquired a more intimate knowledge of the nature of the works required for this railway, and can now offer my remarks with more confidence than I have hitherto been enabled to do.

"My opinion of your line is already well known to you, and it may be unnecessary for me to repeat it. That opinion has undergone no change; and believing that Parliament has exercised a wise discretion in the selection of the direct line, I will content myself with stating that passengers can be conveyed upon it by locomotive engines at a safe and rapid speed—that the gradients will not exceed 1 in 264, nor the curves one mile in radius. The alterations made in the line since it was last under my notice are, in my opinion, judicious; and by the introduction of a tunnel at Merstham, and an extension of those at Balcombe and Clayton, much of the deep cuttings, so strongly objected to in the Committee, has been avoided, and yet there is no deviation of such an extent as to render another application to Parliament necessary.

"The question, however, of the practicability of your line is now considered to be set at rest—there is now no doubt but that the direct line can be made, and that, when made, it can be worked; and the ground being therefore so far prepared, I will proceed at once to the other branches of your inquiry.

"The working plans and estimates of Mr. Rastrick have been laid before me; and although I *might* agree generally with him as to the prices of particular works, I have thought it better to make my estimate entirely on independent grounds. With these materials before me, and with the advantage of my recent inspection of the line, I have estimated the cost of the works, including the excavations and embankments, bridges, tunnels, rails, chairs, sleepers, &c., and every other item belonging to the formation of the railway, and also the sum of 16,000*l.* for stations, and 30,000*l.* for management (but exclusive of the cost of the land and buildings), at the sum of 850,000*l.*, and the Shoreham Branch at 70,000*l.*; and I have no hesitation in expressing my belief that the works may be executed for these sums.

"I ought to observe, that, in forming my estimate, I have not been governed entirely by the propositions of Mr. Rastrick. There may be cases where his plans are superior to those which I might recommend; and, again, I might prefer a peculiar method of execution not approved of by him; but, under all these circumstances, the differences between us are so slight, and our estimates so nearly equal, as to give the assurance that we are not far from the truth.

"The line at Brighton still admits of a slight alteration. I have mentioned this to Mr Rastrick, who will, I doubt not, pay to the suggestion whatever attention it merits.

"The time in which the line may be executed need not exceed two years and a half.

"It is unnecessary for me to trouble you with the details of my calculations, either as to the cost or the time of execution. The aggregate amount is what more directly affects you, than the steps by which the conclusions are obtained; I may, however, be permitted to exceed the limits of my instructions, by venturing an opinion, that contractors are to be found to undertake the work for the amount, and within the time, I have stated

"On the Southampton Railway, heavier works, through more precarious materials, and at a less cost, are now being satisfactorily executed; and, with the experience of those works, I see no reason to apprehend difficulty in encountering those on your line. There is scarcely a district in England where the material is more favourable; and thus the contingencies, both as to cost and time, are rendered less vague than are usual in such cases.

"I wish not, however, to under-estimate the difficulties of your works; they are such as to require vigilant attention. But so much has been said and written on the subject of the Brighton Railway, that the public has been led to believe the formation of any line almost impossible; and I think it right to endeavour to place the subject fairly before you, in order that you may know that your works do not exceed those that have been successfully accomplished on other railways. I am, gentlemen, your obedient servant,

"*London, Dec 8th*, 1837." "JOSEPH LOCKE"

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL ACADEMY.

The president and members of this Institution assembled, as usual, on the evening of Saturday, the 9th of December, 1837, to distribute the medals adjudged at a general meeting on the 1st. Among the visitors we observed Lords Abinger and Lyndhurst, Lord Chief Justice Tindal, Sir John Rennie, Sir J. M'Gregor, R. Vernon, Esq., Samuel Rogers, Esq., and Philip Hardwick, Esq. The president, Sir M. A. Shee, commenced his address by adverting to the loss the Academy had sustained since their last meeting, by the demise of its illustrious patron, William the Fourth, whose loss (although supplied in the person of the beloved and amiable princess who now fills the throne) could not but be a source of the deepest regret to every person connected with the Academy and the Arts. Having concluded his preliminary observations, he proceeded to distribute the medals awarded to the various works of art, expressing the satisfaction felt by the members generally at the ability displayed by the students; but remarking with regret, the want of energy and enthusiasm in the class of original compositions. The distribution was as follows:—

To Mr. E. B. Morris, for the best original Painting, the Gold Medal, and the Discourses of the Presidents Reynolds and West.

To Mr. John A. Gifford, for the best original Design in Architecture, the Gold Medal, and Discourses of the Presidents Reynolds and West.

To Mr. J. Hayes, for the best Copy in the Painting School, the Silver Medal, and Lectures of Professors Barry, Opie, and Fuseli.

To Mr. Samuel Taylor, for a Copy in the Painting School, the Silver Medal.

To Mr. T. H. Harland, for the best Drawing from the Life, the Silver Medal, and Lectures on Professors Barry, Opie, and Fuseli.

To Mr. J. Waller, the Silver Medal was adjudged, but not given, in consequence of his having received a similar premium in the same class.

To Mr. Thomas Burton, for a Drawing from Life, the Silver Medal.

To Mr. Herbert Williams, pupil of Samuel Angell, Esq., for the best Architectural Drawing, the Silver Medal, and Lectures of Professors Barry, Opie, and Fuseli.

To Mr. W. Snook, pupil of Mr. Finden, for an Architectural Drawing, the Silver Medal.

To Mr. A. J. Ashton, pupil of Mr. Finden, for an Architectural Drawing, the Silver Medal.

To Mr. J. Rivers, for a Model from Life, the Silver Medal.

To Mr. W. Carpenter, for the best Drawing from the Antique, the Silver Medal, and Lectures of Barry, Opie, and Fuseli.

To Mr. H. Le Jeune, for a Drawing from the Antique, the Silver Medal.

To Mr. Nelson O'Neal, for a Drawing from the Antique, the Silver Medal.

To Mr. G. Nelson, for a Model from the Antique, the Silver Medal.

The President afterwards delivered an eloquent discourse to the candidates and students.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the first Ordinary Meeting of the Session 1837 8, *held at the New Rooms*, 16, *Grosvenor-street, on Monday, December* 4*th*, 1837; J. B. Papworth, Esq., V. P., in the chair—The President announced for the Council that they had made application, through his Lordship the President, that her Majesty would be pleased to become the Patroness of this Institute, to which application the following reply had been received:—

"Downing-street, Aug. 8, 1837.

"My dear Lord,

"I have laid your letter of yesterday, together with the enclosure, before her Majesty this morning, and her Majesty consents to become the Patroness of the Incorporated Institute of British Architects.

"Believe me, my dear Sir,

"Yours faithfully,

"The Earl de Grey, &c. &c." "MELBOURNE."

James Medland, Esq., Architect, of Gloucester, was elected an associate. Letters were read from the Imperial Academy of Venice, the Royal Academy of Fine Arts of London, and the Manchester Architectural Society.

Several donations were announced, among which was a splendid volume of 93 original drawings by Panini, Bibiena, Oppenord, Moucheron, Benvenuto Cellini, and other celebrated artists, presented by Sir John Drummond Stewart of Scotland, through C. Barry, Esq., V. P.

John Blore, Esq. Associate, read the first part of a very interesting paper on the History of the English School of Gothic Architecture, which we regret cannot be transcribed to our pages, in consequence of its great length.

A communication was read from the Chevalier Von Kleuze, honorary and corresponding member at Munich, describing a Peripteral Ionic Temple, erected by him in Munich Park, and decorated with Polychromatic embellishments.

Messrs. Bunnett & Corpe, of Lombard Street, exhibited a Model of their patent revolving safety Shutters, and described the principle of their construction.

A second ordinary Meeting, on Monday, Dec. 18, 1837, P. F. Robinson, Esq., V.P., in the Chair. Sir R. Peel, Bart., was elected an honorary member; also several distinguished foreign architects were elected honorary fellows. Letters were read from Dr. Moller, of Darmstadt, accompanying a beautiful engraving of the Cathedral at Cologne; from M. Vaudoyer, of Paris, with several presents; and from M. Bolsato, Professor in the Fine Arts Academy, Vienna, all containing complimentary congratulations on the position taken by the Institute. The secretary announced, among other donations, seven views in Rome, from Mr. P. Thompson; "Fonthill Abbey," from Mr. Davy; Leoni's Works, from Mr. Chantrell; and Specimens from Mr. Hardwick. Mr. Godwin, Jun., presented two panels of stamped and painted Leather from Harrington house, lately pulled down. The second part of an interesting paper on English Architecture, by Mr. Blore, was read; a communication from Mr. Chantrell, of Leeds, was read, relative to the working of Yorkshire stone-quarries. Mr. T. L. Donaldson submitted some suggestions on the expediency of establishing an universal system of notation for architectural admeasurements. Mr. Cole furnished an interesting sketch and description of a Screen in Dartmouth Church, which is elaborately painted and gilded. Baron Wetterstedt described a new Metal for covering roofs; and Mr. T. Roe explained the construction of his Patent Water Closet.

The Meeting was adjourned to Monday, January 13.

ARCHITECTURAL SOCIETY.

This Society held their usual meeting at their Rooms on Tuesday evening, November the 21st, in Lincoln's Inn Fields. T. L. Walker, Esq., Honorary Treasurer, in the Chair. Several donations were received, and which the Secretary was requested to duly acknowledge. A paper of considerable interest on the subject of bricks was then read by J. Turner, Esq., on the conclusion of which the subjects for the sketches at the next meeting were announced. For Members—their opinions as to the best mode to be adopted for laying out the space before the National Gallery, called Trafalgar Square, to be accompanied by sketches or descriptions necessary to elucidate the same. For Students—a design for an Entrance Hall to a Nobleman's Mansion, with Staircase and Saloon.

Meeting 5th Dec., 1837.

F. H. Wyatt, V.P. in the Chair. Mr. Geo. Rutherford, Jun., was elected Student Member; and Mr. Manby, an Amateur Member.—Several donations were announced.

The subjects for the Sketches at the next Meeting were announced as follows:—Members' Subject, *Entrance to a Railroad Station.* Students' Subject, *Entrance-doorway to a Town House, without a Portico.* An interesting paper on the "Properties of Sound" was read by R. E. Philips, Esq., Member.

NOTICE TO STUDENTS.—MR. OWEN JONES (Member) has announced his intention of giving a Gold Copy of his Work on the Alhambra, to the Student who produces the most approved measured finished drawings and details of the Garden Front of the Travellers' Club House. MR. GEO. MAIR (Member) has announced his intention of *annually* giving an Architectural Work, to be awarded to the Student Member who produces, during the lessons, the greatest number of approved Sketches agreeable to the instructions of the Sketch Committee.

SOCIETY OF ARTS.

Mr. Aikin "On Calico Printing," No. 2.—After recapitulating the heads of the first Lecture on the same subject, the secretary proceeded to observe, that the chintz and palampore of India long continued to be the prototypes of European printed calicoes, in which the colours are distributed more or less in masses representing flowers and other natural objects. For these nothing but wooden blocks can be employed; as wood is the only material which with any convenience will allow of the insertion of pieces of felt, necessary in those parts of the pattern where a considerable quantity of mordant is required; and, therefore, even at the present day, for such kinds of patterns, block printing is universally practised. At length, in the change of fashion, stripes, sprigs, running foliage, and other simple and neat, but rather unmeaning patterns, raised in one colour, were introduced. It was soon found that such patterns could be represented with more delicacy and precision by copper-plate engraving than on wood. The plate and rolling-press were, therefore, introduced into the calico-printer's workshop, instead of the block and mallet. The spirit of competition, a rapidly extending market, and the ambition of "ridding" much work with a comparatively small profit, soon occasioned the substitution of the copper cylinder instead of the plate. The mordants, mixed with gum to the consistence of printer's ink, were distributed on the plate, first by hand, and then by machinery; which last, with the necessary modifications, was adapted to the cylinder. The time thus saved encouraged the calico-printers to give more precision to their machinery, by means of which, at the present day, they are capable of working two, and even three, cylinders, each distributing a separate mordant at the same time to the same piece of cloth, and at a rate which enables them to finish a piece in three minutes, and with a degree of precision, all things considered, truly surprising. Mr. Aikin, then, in a clear and simple manner, explained the chemical part of the process, by means of which such an almost infinite variety of tints and colours are produced; but, as it would be impossible, in the space allotted to this report, to follow the notes of the lecturer through the whole of these details—interesting as they are—and, as it would be equally impracticable to give a satisfactory analysis of them, we pass them over, and conclude by noticing the facility with which many compound or simple dyes on calico may be resolved or analyzed by the use principally of three re-agents, viz., bleaching liquor, solution of carbonate of potash, and of oxalic or tartaric acid. Indigo blue may be distinguished from Prussian blue by the action of bleaching liquor, which will destroy the indigo, but has no effect on Prussian blue; or by the use of carbonated alkali, which does not touch indigo, while it turns Prussian blue to an iron brown. All vegetable and animal colours yield to bleaching liquor; those that do not, are mineral or chemical colours: a colour, therefore, that is compounded of both kinds, may be resolved by the action of this substance. Chrome yellows are shown by their habitudes with carbonated fixed alkali, and by their becoming dark brown after the action of alkali, when touched with solution of an alkaline sulphuret. Iron yellows are soluble in tartaric acid, which chrome yellow is not. Greens, composed of yellow and blue, if both ingredients are vegetable, are discharged by bleaching liquor; if the yellow is chrome, and the blue is indigo, the action of carbonated alkali will discharge the yellow, leaving the blue, while that of bleaching liquor will discharge the blue, leaving the yellow. Brown, composed of oxide of manganese and madder, is resolved by bleaching liquor, which leaves the manganese, or by proto-muriate of tin, which dissolves the manganese.

In the museum were exhibited specimens of wheat, raised by cottagers, by means of dibbling, six inches apart. A memorandum, accompanying the specimens, set forth, that one individual began dibbling one grain of wheat to the square foot, which sprang up regularly, and yielded him forty-two bushels to the statute acre—a large return for 4lbs. 10oz. of seed. The specimens exhibited were prize specimens of the Battel and Hastings Horticultural Society, and measured five feet and a half in height, with ears proportionally large and full.

Minutes of Proceedings of the Institution of Civil Engineers, containing Abstracts of Papers, and of Conversation for the Session of 1837.

(Continued from Page 40.)

"March 21, 1837.---The President in the Chair.

"'*On the strength of Iron Girders, by W. B. Bray, A.Inst. C.E.*'

"In this paper the author states the rules which had been given by Galileo, Tredgold, and Hodgkinson, for calculating the strength of iron girders. He shows by a table that Galileo's rule must be utterly false when applied to girders having large bottom flanches. Applying this rule to two girders, one of which contains double the metal of the other, they ought to be of the same strength, whereas Mr. Hodgkinson's rule makes the former only one-half as strong as the latter. Tredgold gives no rule for the case of a large bottom flanche. Thus there appears great inconsistency in these rules, and a formula applicable to all cases is still wanted.

"'*On Mr. Hodgkinson's Experiments on Cast Iron Girders, by Thomas Webster, M.A.; Sec.Inst. C.E.*'

"The object of this paper was to detail the result of an examination of the above experiments, undertaken with the view of ascertaining whether those forms of beams recommended by Mr. Hodgkinson as requiring greater breaking weight have also a greater elastic weight than the more ordinary forms, with equal flanches at the top and bottom. The principle assumed by Tredgold (which also was the principle assumed by Dr. Young) is, that within the elastic limit the forces of extension and compression are equal; whereas Mr. Hodgkinson starts with the inquiry as to the law which connects the forces of extension and compression.

"Mr. Hodgkinson's experiments must be viewed as directed entirely to determining the breaking weights, and the earlier weights are not set down in many of the experiments. The weights and deflections first recorded are in many cases very near the elastic weight and point of permanent set, so that there is great difficulty in applying the principle already laid down for determining the elastic weight. But in some of the experiments, which have a long series of weights, it will be seen, on comparing the increase of deflection with the increase of weight, that this ratio changes from one of equality sooner in these forms than in those with equal flanches at the top and bottom. If then these beams with large bottom flanches do possess practical advantages, it may be from their allowing a violation of the elastic limit with comparative safety; this is a state of things, however, which ought never to be contemplated.

"April 4, 1837.---Bryan Donkin, Esq., V.P., in the Chair.

"'*Result of experiments made with a view to determine the best figure and position for wooden bearers, so as to combine lightness and strength; by James Horne, F.R.S.; A. Inst. C.E.*'

"The results of several experiments on wooden bearers of different sections are tabulated; together with the dimensions and weights of the pieces, and the nature of the fracture. The conclusion at which Mr. Horne arrives is, that a triangular prism placed with its base upwards is the strongest figure and position; that with an edge uppermost the weakest for a given quantity of material.

"The subject of the vibrations produced in the soil by the passage of Locomotives and Coaches was discussed, and several instances were mentioned in which the vibration of the soil was sensible at the distance of a mile and a half during an observation by reflexion. It was stated that the experiments recently made for determining the effect which the passage of the locomotives at a small distance might have on the observations at the Royal Observatory had not been conclusive; but that as no sensible effect could be produced on any observations but those by reflexion, no apprehension of inconvenience was entertained.

"It was also stated that a number of persons running down the hill in Greenwich park produces a slight tremor, which is quite sensible during an observation by reflexion, and that the shutting of the outer gate of the Observatory throws an object completely out of the field of the telescope.

"The comparative merits of the Single Pumping and of the Crank Engine for the purposes of raising water were discussed.

"Mr. Simpson stated that it was a generally received opinion that a Single Pumping engine would do one-third more duty than a Crank engine: but that having recently had a Crank engine altered by Messrs. Maudsleys and Field, and fitted with expansion valves, it did the most duty. The two engines were worked from the same boiler. The duty of the Crank engine was about thirty-two millions; it works to a fixed lift, which is in some respects advantageous. The duty of the Cornish engines is reported at ninety five millions, and an engine near London, in which the Cornish valves and system of clothing had been adopted, was doing a duty exceeding fifty millions.

"With respect to the Cornish engines, it was stated that their superior duty is due to the system of clothing; that although many persons had examined their duty, the calculations appear to be made from the contents of the working barrel; that the Cornish bushel is 90 or 94lbs. of a very superior coal, the London bushel being only 80 or 84lbs.; that notwithstanding the great duty done by the pumping engines, the crank engines in Cornwall are doing less duty than the crank engines in London.

"'*Notice concerning the Thames Tunnel. By Richard Beamish, M.Inst. C.E.*'

"Several attempts have been made in former years to effect a communication betwixt the opposite shores of the Thames by means of a Tunnel, all of which, however, failed. In 1798, Dodd proposed a Tunnel at Gravesend; and in 1801, Chapman projected one at Rotherhithe; and in 1807, Vazie commenced the construction of a shaft, 11 feet diameter, at a distance of 315 feet from the river. With Vazie was associated Trevethick, a man of great practical knowledge as a miner, and by indefatigable labour a drift-way 5 feet in height, 2 feet 6 inches in breadth at the top, and 3 feet at the bottom, was carried 1,046 feet under the river. In the spring of 1808, having first ascended from under a rocky stratum, though with a depth of at least 25 feet betwixt them and the bed of the river, the Thames broke in upon them, and not a single brick having been laid the work was irretrievaby lost.

"In 1823 the subject of a Tunnel was again agitated, and a company was formed to carry into execution the plans of Mr. Brunel. The first proceeding was to sink a shaft. Twenty-four piles with a shoulder on each were first driven all round the circle intended for the shaft. One side of a wooden platform or curb was then laid on *this* shoulder, whilst the other side rested on an iron curb, having an edge *below* to which it was attached. Through this curb ascended forty-eight wrought-iron bolts, 2 inches diameter, to the height of 40 feet, the height to which it was proposed to raise the shaft.

The regular building of the tower on the curb with bricks laid in cement was proceeded with, and yet farther bound together by twenty-six circular hoops of timber, half an inch thick, as the brick-work was brought up. At the top of the tower was placed another curb, and the long iron bolts passing through it, having their ends formed into screws, the whole was screwed solidly into one mass, and completed in three works. In a week after it was finished sixteen of the piles having been driven, two by two opposite each other, the whole structure was sunk half an inch, carrying down with it the remaining eight piles, on which it was brought to a rest uniformly and horizontally, thus permitting the sixteen piles to be abstracted by opening the ground at the back. The whole weight supported by these eight piles was about 910 tons (the weight of the shaft). Having been left for three weeks to dry, and gravel having been heaped under the curb, the remaining eight piles were removed, two by two, till the mass rested on a bed of gravel. The machinery, viz., the thirty-horse high pressure steam engine, with gear for raising the excavated soil, was now fixed on the top. The miners were placed inside, and by excavating from around the bottom, the whole descended by its own gravity.

" Mr. Beamish then describes the peculiar difficulties which were experienced previous to the first irruption.

" The chasm in the bed of the river, formed by the irruption of 1827, was stopped by bags filled with clay, with hazel rods passed through them; and the interstices filled by gravel. The irruption of 1828 was met by similar means, but the funds of the company not being then sufficient for proceeding with the work, the shield was blocked up with bricks and cement, and a wall 4 feet in thickness was built within the Tunnel.

" For seven years the work was abandoned, till in 1835 a Treasury loan was granted, subject to the condition that the most dangerous part of the Tunnel should be executed first. On resuming the works, the first object was to provide a drain for the water from the shield, for which purpose two reservoirs were formed under the middle pier, from which drifts were formed to the bottom of the great excavation and shield. The water was abstracted from the shield at the lowest point, and the pipes of two pumps worked by the steam engine being brought into the reservoir, all the difficulty of the drainage was overcome.

" The removal of the old and the introduction of the new shield was a work of no ordinary difficulty. The bricks and cement had, by the strong oxide of iron which the water contains, been converted into a mass harder than most rocks; and not less than 1616 of surface, 312 of which constituted the ceiling, had to be supported on the removal of the brick work previous to the introduction of the new shield. The means however adopted by Mr. Brunel, and which are described in the paper, were perfectly successful.

" April 11, 1837.---The President in the Chair

" Mr. Brunel gave an account of the Thames Tunnel. --Having described the nature and difficulties of the undertaking, and the previous attempts which had been made by others to effect a similar work, he explained by reference to sections the nature of the strata below the river. He had adopted the rectangular form of the present excavation, because the work would set better than if of any other form, and had a better sustaining surface. The necessity of supporting the ground, and of having a sufficient shelter, had led to the adoption of the shield respecting which so much had been said. The construction of this would be understood by conceiving twelve books set side by side on their ends. These would represent the parallel frames which, standing side by side, but not in immediate contact, fill up the excavation. Each frame is divided into three boxes or cells, one above the other; the adjustment of the floors of which, and other details, were minutely described by Brunel.

" Each frame is furnished with two large slings, by which it may derive support from or assist in supporting its neighbours; it has also two legs, and is advanced as it were by short steps, having for this purpose an articulation which may be compared to that of the human body. The frame rests on one leg, and then one side is hitched a little forward; then resting on the other leg, the other side is hitched a little, and so on. Hence the shield may be called an ambulating coffer dam, going horizontally.

" The brick-work is built in complete rings, and the advantages of this system of building had been fully proved by the fact of two dreadful irruptions having produced no disruption. Such was the violence of the irruption, that the brick-work had in one part been suddenly reduced in thickness by one-half, and in one place there was a hole as if pierced by a cannon-ball. At a few feet beneath them is a bed of quicksand 50 feet deep, and above them strata of most doubtful consistency, some of which goes to pieces immediately on being disturbed. Still, however, their progress is certain, and they only required patience to allow of the ground above them acquiring sufficient density. He found gravel with a mixture of chalk or clay extremely impervious to water; in some cases he contrived to let the water from the sand above them, and thus obtained ground of sufficient density. In their progress they were considerably annoyed by land springs, which produced cutaneous irruptions, and destroyed the finger nails of the workmen.

" April 18, 1837.---The President in the Chair.

" Mr. Brunel gave further explanations respecting the Tunnel. He explained the way in which the ground above them had suddenly sunk down, owing to the run of a lower stratum of sand. This running sand, which was a very great annoyance, consisted of *five* parts water and *one* sand. Bags of clay and gravel are not best where there are many stones; for the interstices do not become properly filled up; but in these cases the coarsest river sand is best; the water runs through at first, but soon stops; gravel and clay mixed are nearly impervious to water, but not so impervious as gravel and pounded chalk.

" Mr. Gibb stated that he had found bags filled with clay and tow-waste exceedingly impervious to water. Being called upon to rebuild a sluice in a place where piling, owing to the stony nature of the ground, was impossible, he had formed a coffer-dam by laying down bags full of clay and tow-waste, in tiers of four, formed on the top of each other to the surface of the water.

" The Ventilation of the Tunnel is effected by a pipe 15 inches square passing out under the fire-place of the steam engine boiler.

" ' *Description of a proposed Levelling Machine. By John Harrison.*'

" Mr. Harrison proposes to construct a machine which should make its own section of the country as it passes over it. This machine, of which the general appearance is like a caravan, is to be drawn on four wheels by horses, the machinery being moved by the wheels of the carriage. A section is generally made by marking on the base line the lengths; and on perpendiculars through these points the heights; and joining the points so marked off. But in this machine the section is to be made by the continued motion of a point acted on by two forces, one of which would carry it in a horizontal line uniformly with the space gone over by the machine, and the other vertically, according as the machine is rising or falling. The machine is thus divided into two distinct parts for effecting these purposes, and the way in which this may be practically effected is described in detail by reference to an isometrical drawing accompanying the paper.

" April 25, 1837.---The President in the Chair.

" The paper by Mr. Beamish, which had been commenced at a previous meeting (April 2), was concluded.

" Mr. Trubshaw presented to the Institution a model of the Centre employed by him in the construction of the Chester bridge.

" The peculiar features of this Centre, which is described in detail in the first volume of the Transactions, consist in the absence of horizontal timbers, the timbers being so arranged that their load is received end-ways, and in the lagging being supported over each rib by a pair of folding wedges.

" Mr. Trubshaw entered into the details of the construction and method of striking the Centre, explanatory of the account contained in the Transactions.

" Mr. Macneill explained a method which he had recently adopted of laying down the sections of Railways so as to show at once to the eye the position of the cuttings and embankments; and a scale being laid upon the section, their heights and lengths are at once known, in the same way as by measurement on a detached section. This method will be understood by conceiving the line of railway traced on a map of the country, and a coloured part above to represent where a cutting has been made, and a differently coloured part below where an embankment has been made. The outlines of these will show at once the dimensions of the cuttings and embankments; in engraved plans, he should represent the cuttings by lines, and the embankments by dots, or stipling. The usual sections would of course be used by engineers, but a section similar to this would convey at once all the information requisite for committees. Two or more lines being projected in this way, the reasons for selecting one in preference to the others would, in many cases, appear at a single glance.

" Mr. Macneill proposes also to adopt the terms acclivity and declivity with a rate marked after them. Starting then from the metropolis, or some principal town, all the ascents would be acclivities, and the descents declivities. Thus all the information generally required would be conveyed by the inspection of a single section.

EXTRACT FROM AN ESSAY READ BEFORE THE ARCHITECTURAL SOCIETY, ON TUESDAY, DEC. 5TH, 1837. BY R. E. PHILIPS, ESQ. ARCHITECT.

ON SOUND.

Sound is a term, of which, perhaps, it is quite unnecessary to offer any definition; but, when we consider it as a sensation, or still more, when we consider it as a perception, it may not be deemed superfluous to give a short description. Sound is that primary information which we obtain of external things by means of the sense of hearing. Those of the ancients, therefore, who taught that sounds were beings wafted through the air, and felt by our ears, should not even at this day be considered as awkward observers of nature. It has required the long, patient, and sagacious consideration of the most penetrating geniuses, to discover that what we call sound, the immediate external object of the sense of hearing, is nothing but a particular agitation of the parts of surrounding bodies, acting by impulse on our organs, and that it is not any separate being, nor even a specific quality inherent in any particular thing, by which it can affect the organ, as we suppose, with respect to a perfume, but merely a mode of existence competent to every atom of matter.

Most sounds, we all know, are conveyed to us on the bosom of the air; in whatever manner they either float upon it, or are propelled forward in it, certain it is, that without the vehicle of this or some other fluid, we should have no sounds at all. Let the air be exhausted from a receiver, and a bell shall emit no sound when rung in the void, for as the air continues to grow less dense, the sound dies away in proportion, so that at last its strongest vibrations are almost totally silent. Thus air is a vehicle for sound; however, it is not the only vehicle; that if there were no air, we should have no sounds whatever; for it has been found by experiment, that sounds are conveyed through water with the same facility with which they move through air. A bell when rung in the water returns a tone as distinct as if rung in the air. It appears from experiments by naturalists, that fishes have a strong perception of sounds even at the bottom of deep rivers; hence it appears not to be

very material in the propagation of sounds, whether the fluid which conveys them be elastic or otherwise. Water, which of all substances that we know has the least elasticity, yet serves to carry them forward.

But though air and water are both vehicles of sound, yet neither of them, according to some philosophers, seems to be so by itself; but only as it contains an exceedingly subtle fluid, capable of penetrating the most solid bodies; hence by the medium of that fluid, sounds can be propagated through wood or metals. By the same means deaf people may be made sensible of sounds, if they hold a piece of metal in the mouth, one end of which is applied to the sounding body. One thing however is certain, that whatever the fluid which conveys the note be—elastic or non-elastic—whatever sound we hear is produced by a stroke, which the sounding body makes against the fluid, whether air or water, the fluid being struck upon carries the impression forward to the ear, and there produces its sensation. Upon this point philosophers are agreed; but the manner in which this conveyance is made is still, I believe, a subject of doubt. Whether the sound is diffused into the air, in circle beyond circle, like the waves of water when we disturb the smoothness of its surface by dropping in a stone, or whether it travels along like rays diffused from a centre, somewhat in the swift manner that electricity runs along a rod of iron, are questions which have divided the learned.

Newton was of the first opinion; he has explained the progression of sound by an undulatory, or rather a vermicular, motion in the parts of the air. If we have an exact idea of the crawling of some insects, we shall have a tolerable notion of the progression of sound upon this hypothesis. The insect, for instance, in its motion first carries its contractions from the hinder part, in order to throw its fore part to the proper distance, then it carries its contractions from the fore part to the hinder, to bring that forward. Something similar to this is the motion of the air when struck upon by a sounding body; in the mean time, while the parts of the first range are thus falling back, the parts of the second range are going forward with an accelerated motion; thus there will be an alternate condensation and relaxation of the air during the time of one vibration, and as the air going forward strikes any opposing body with greater force than upon retiring, so each of the accelerated progressions have been called by Newton a pulse of sound, but we must bear in mind that these pulses move every way, for all motion, impressed with fluids in any direction whatsoever, operates all around in a sphere, so that sounds will be driven in all directions, backwards, forwards, upwards, and on every side; they will go on succeeding each other like circles in a disturbed water, or rather they will lie one on another in concentric shells, as we observe the coats of an onion. All who have remarked the tone of a bell while its sounds are decaying away, must form an idea of the pulses of sound, which according to Newton are formed by the air's alternate progression and recession.

As to the velocity with which sounds travel, this Newton determines, by the most difficult calculation that can be imagined, to be in proportion to the thickness of the parts of the air, and the distance of these parts from each other. He goes on to demonstrate, that if the atmosphere were of the same density everywhere, as at the surface of the earth, in such a case, a pendulum that reached from its highest surface down to the surface of the earth, would by its vibrations discover to us the proportion of the velocity with which sounds travel; the velocity with which each pulse would move, he shows, would be as much greater than the velocity of such a pendulum, swinging with one complete vibration, as the circumference of a circle is greater than the diameter; from hence he calculates that the motion of sound is 979 feet in one second; but this not being consonant to experience, he takes another consideration, which destroys entirely the rigour of his former demonstration, namely, vapours in the air, and then finds the motion of sound to be 1,142 feet in one second, or near 13 miles in a minute; a proportion which experience has nearly established.

Various have been the objections that have been made to the Newtonian system of sounds, and many are the theories of sound. We find the following explanation given by the late Dr. Matthew Young, in its defence:—

"1. The parts of all sounding bodies vibrate according to the law of a cycloidal pendulum, for they may be considered as composed of an indefinite number of elastic fibres; but these fibres vibrate according to that law.

"2. Sounding bodies propagate their motions on all sides in directum, by successive condensations and rarefactions, and successive goings forward, and returnings backward of the particles.

"3. The pulses are those parts of the air which vibrate backwards and forwards, and which, by going forward, strike against obstacles. The latitude of a pulse is the rectilineal space through which the motion of the air is propagated during one vibration of the sounding body.

"4. All pulses move equally fast. This is proved by experiments, and it has been found that they describe 1,070 Paris feet, or 1,142 London feet in a second, whether the sound be loud or low, grave or acute."

Monsieur Sauveur, by some experiments on organ pipes, found that a body which gives the gravest harmonic sound, vibrates twelve times and a half in a second; and that the shrillest sounding body vibrates 51,100 times in a second. At a medium, take the body, which gives what Monsieur Sauveur calls his fixed sound, it performs 100 vibrations in a second, and, in the same time, the pulses describe 1,070 Parisian feet.

The method of calculating sound in its progress is easily made known. When a gun is discharged at a distance, we see the fire long before we hear the sound. If, then, we know the distance of the place, and know the time of the interval between our first seeing the fire and then hearing the report, this will show us exactly the time the sound has been travelling to us.

For example, suppose you see the flash of a gun in the night at sea, and tell seven seconds before you hear the report, it follows, therefore, that the distance is seven times 1,142 feet—that is, 24 yards more than a mile and a half. In like manner, if you observe the number of seconds between the lightning and the report of the thunder, you know the distance of the cloud from whence it proceeds. Corrected by the experiments of various observers, the velocity of any impression transmitted by the common air, may at an average be reckoned 1,130 feet in a second. Derham has proved by experiments, that all sounds whatever travel at the same rate. The sound of a gun, and the striking of a hammer, are equally swift in their motions. The softest whisper flies as swiftly, as far as it goes, as the loudest thunder.

To these axioms we may add the following:

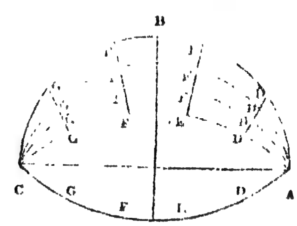
Smooth and clear sounds proceed from bodies that are homogeneous, and of an uniform figure, and harsh or obtuse sounds from such as are of a mixed matter, and irregular figure.

The velocity of sounds is, to that of a brisk wind, as fifty to one.

The strength of sounds is greatest in cold and dense air, and least in that which is warm and rarefied. Every point against which the pulses of sound strike, becomes a centre, from which a new series of pulses are propagated in every direction. Sound describes equal spaces in equal times.

Sound, like light, after it has been reflected from several places, may be collected in one point, as into a focus, and it will be there more audible than in any other part, even than at the place from whence it proceeded. On this principle it is that a whispering gallery is constructed.

The form of a whispering gallery must be that of a concave hemisphere, as ABC, and if a low sound or whisper be uttered at A, the vibrations expanding themselves every way will impinge on the points DDD, &c., and from thence be reflected to EEE, and from thence to the points F and G, till at last they all meet in C, where, as we have said, the sound will be most distinctly heard. When we speak in the open air, the effect on the tympanum of a distant auditor is produced merely by a single pulse; but when we use a tube, all the pulses propagated from the mouth, except those in the direction of the axis, strike against the sides of the tube, and every point of impulse becoming a new centre, from whence the pulses are propagated in all directions, a pulse will arrive at the ear from each of those points; thus, by the use of a tube, a greater number of pulses are propagated to the ear, and consequently the sound increased. The confinement of the voice, too, may have a little effect, though not such as is ascribed to it by some, for the condensed pulses produced by the naked voice freely expand every way; the substance of the tube likewise has its effect, for it is found, the more elastic the substance of the tube, and consequently the more susceptible it is of these tremulous motions, the stronger is the sound.



An echo is a reflection of sound striking against some object, as an image is reflected in a glass; but it has been disputed what are the proper qualities in a body for thus reflecting sounds. It is generally known that caverns, grottos, mountains, and ruined buildings, return this reflection of sound; we have heard of many extraordinary echos, and no doubt most of us have experienced many ourselves.

It has been already observed, that every point against which the pulses sound strike, becomes the centre of a new series of pulses, and sound describes equal distances in equal times; therefore, when any sound is propagated from a centre, and its pulses strike against a variety of obstacles, if the sum of the right lines drawn from that point to each of the obstacles, and from each obstacle to a second point be equal, then will the latter point in which an echo will be heard.

Now it appears from experiments, that the ear of an excellent musician can only distinguish such sounds as follow one another at the rate of nine or ten in a second, or any slower rate; and therefore, for a distinct perception of the direct and reflected sound, there should intervene the interval of one ninth of a second; but in this time, sound describes nearly 127 feet, and therefore, unless the sum of the lines drawn from each of the obstacles exceeds the interval by 127 feet, no echo will be heard. Hence all the points of the obstacles which produce an echo must lie in the surface of the oblong spheroid, generated by the revolution of this ellipse round its major axis. However, an echo may be heard, in other situations, though not so favourably, as such a number of reflected pulses may arrive at the same time at the ear, as may be sufficient to excite a distinct perception. At the common rate of speaking, we pronounce not above three syllables and a half—that is, seven half syllables in a second; therefore, that the echo may return just as soon as three syllables are expressed, twice the distance of the speaker from the reflecting object must be equal to 1,000 feet; for, as sound describes 1,142 feet in a second, six-sevenths of that space, that is 1,000 feet nearly, will be described, while six half, or three whole syllables are pronounced—that is, the speaker must stand near 500 feet from the obstacle, and, in general, the distance of the speaker from the echoing surface, for any number of syllables must be equal to the seventh part of the product of 1,142 feet, multiplied by that number. In churches we never hear a distinct echo of the voice, but a confused sound, when the speaker utters his words too rapidly, because the greatest difference of distance between the direct and reflected courses of such a number of pulses as would produce a distinct sound, is never in any church equal to 127 feet, the limit of echos.

Monsieur De la Grange has also demonstrated, that all impressions are reflected by an obstacle, terminating an elastic fluid, with the same velocity with which they arrived at that obstacle.

When the walls of a passage, or of an unfurnished room, are smooth and

perfectly parallel, any explosion, or a stamping of the foot, communicates an impression on the air, which is reflected from one wall to the other, and from the second again towards the ear, nearly in the same direction with the primitive impulse; this takes place as frequently in a second, as double the breadth of the passage is contained in 1130 feet, and the ear receives a perception of a musical sound thus determined in its pitch by the breadth of the passage. On making the experiment, the result will be found to correspond. The appropriate notes of a room may be readily discovered by singing the scale in it, and they will be found to depend on the proportion of its length or breadth to 1130 feet.

In having thus given but a vague and perhaps unsatisfactory account of the science of acoustics, as connected with architecture, I trust my hearers will admit that there is much which strongly appertains to the profession to which we have the honour to belong. In our churches, in our theatres, in our public halls, sound is a matter of deep consideration, or ought to be. To fulfil the intentions intended, therefore, the words of Vitruvius, as to the architect being some little acquainted with music, is not altogether a fallacy, but rather a desirable object. Let us then anticipate a new era in our architecture; let us hope it will be held up on the classic grounds of Oxford and Cambridge, as the necessary harbinger of a liberal education.

AN ESSAY ON BRICKS,

Read by J. Turner, Esq., before the Members of the Architectural Society.

"Architecture," our great master, Vitruvius, says, "is a science arising out of many other sciences." Indeed, so numerous are they, and so interesting is the study of each, and of the arts connected with them, to an Architect, that I feel little apology is necessary in the selection of the subject of this Essay.

The universal use of brick, as a material for building, at the present day, its unparalleled applicability, and its wonderful resistance to the ravages of time, have induced me to collect a few records of its antiquity, the material used in its manufacture, and the method of building with it in this and other countries.

It appears that after the Deluge, and before the time of Nimrod, the inhabitants of Assyria lived chiefly in tents and caves. The great Prince, Nimrod, united his subjects in cities, and the first city founded, and known in history, is Babel, wherein we find that immense structures were raised, from the facility of preparing brick by mere solar heat; and however improved that city may have been by Semiramis, wife of Ninus, the erection of the celebrated Tower is generally ascribed to Nimrod, and of which the Birs Nemroud is by some supposed to be the remains. At the Birs Nemroud, are brown and black masses of brickwork, more or less changed into a vitrified state. These masses, however, are found on the summit of the pile, and were evidently vitrified by subsequent conflagration, thought to have been formed by the immense heaps of wood burnt upon the tops of hills in the ancient fire worship; piles of such magnitude, that they were loftier than the hill, and were visible at the distance of 1000 stadia, and heated the atmosphere to such a degree, that the spot could not be approached for several days.

The Babylonian bricks are found to be of two kinds; the sun dried and kiln-burnt. In countries where the sun is powerful, and it seldom rains (in Chaldea not for eight months in the year, occasionally not for two years and a half together), the sun-dried bricks were sufficient for most purposes.

The first walls of Mantinea wholly consisted of them, and they were found to resist warlike engines better than stone.

The bricks are found to be composed of pure clay, and although only baked in the sun, they are so solid and compact as to ring, if placed on the edge, and gently stricken by any metallic body; they were shaped in moulds, supposed to be of wood, having figures and inscriptions, and were beaten up with straw or rush to increase cohesion, and bound in their courses by layers of mortar and reeds.

The curiosity of the bricks at the Birs Nemroud (says Mr. Rich), both sun-dried and kiln-burnt, is the inscription; the language is Chaldee, the system of letters alphabetical, not symbolical, and each figure a single letter, not a compound character or word.

It was customary to inscribe astronomical observations on bricks or columns, and probably these inscriptions were of a talismanic character, for the inscribed parts were always turned down, so that the writing might not be seen or read. Sometimes both face and edge were inscribed, sometimes only the edge; and this is the more rare and valuable of these bricks; some contain 10 lines in an upright column, and some are stamped across to the angles of the bricks.

The kiln-burnt bricks were of far superior induration; they compose the piers and arches of a bridge mentioned by the prophet Baruch, and still remaining; some of them were varnished, and adorned with figures; and they have been found disposed in mosaics, in the figure of a cow, the sun, and moon. The colour is a bright red or pale yellow; in the unburnt, that of stone. The sizes vary from 12 to 13 inches long, 3 or 4 inches thick; the largest known, however, measure 19¾ inches square, and 3½ inches thick, with the written characters along the sides. Some of these bricks have been found of a cylindrical form, inclining to a barrel entasis; they are made of the finest furnace-baked clay, and inscribed with a small running-hand; from the perforation of some, they are presumed to have been worn as amulets or talismans.

In the cement used, lime appears to have been deemed most fit for the upper parts of a building. Captain Mignan, speaking of the Birs Nemroud, says the bricks are 13 inches long by 4½ thick, and are cemented together with a coarse layer of lime, upwards of an inch deep; they are not level, but slope gently from the north face towards the east, and from the east towards the south. Bitumen, which is to be found at the base of most of the ruined structures, is likewise discernible in the pile; none is to be found in the upper portion.

In some instances, neither lime nor bitumen were used, only simple clay. As to the layer of reeds, Herodotus says, "that they were placed at every thirtieth course;" but modern travellers find them at every sixth, seventh, and eighth course, in Aggarkuff, and at every course in some buildings in Babylon.

In Egypt, in such parts as were subject to the inundation of the Nile, towns could not be founded except upon artificial substructures made above the level of its rise; and from Herodotus we learn that the Ethiopians, when they seized Egypt, killed none of the conquered, but employed them in raising heaps of earth; and these artificial superstructures, Sir William Drummond observes, were composed of rubble, surrounded with enclosures built of bricks. Pliny gives us the statement of some old writers, who say, that in the construction of the Pyramids, causeways were made of bricks made of mud, which, upon completion of the work, were distributed among the private houses.

It appears, however, that the Egyptians not only used that material as an accessary to erecting those enormous piles, but also built some with it; and Pococke thus describes one he met with:—"About two miles to the east of the last great Pyramid (at Saccara), on lower ground, and near the east edge of the mountain, is the Pyramid built of unburnt brick. I observed, on the north side, the bricks were laid lengthways from north to south, but not every where in that direction; however, I took particular notice that they were not laid so as to bind one another; it is much crumbled and ruined; it is 157 feet on the north side, 210 feet on the west, it being much broken away on the east and west sides; it is 150 feet high."

And it appears from his and other travellers' accounts since, that no improvement has taken place in the manufacture of this important material, where in eastern countries it still continues to be made, and used as in its most primitive state of invention, many of their houses being built of unburnt bricks made of earth and chopped straw dried in the sun.

In tracing this subject to more classic ground, Greece,

"Where demi gods appeared, as record tell,"

we find that the native materials of the country led men to form their superstructures in accordance with the gifts of nature, which in a great measure superseded all auxiliaries, and the style of their architecture rendered stone or marble more convenient and effective; but it was not altogether rejected in their buildings. And here we have that consideration given to their form and size as should make the work executed with them appear not only more agreeable to the sight, but render it also more solid in construction. Hence Vitruvius tells us the Greeks had three kinds of brick; two sorts only were used in public buildings; each sort had half bricks made to suit it, so that when a wall was executed, the course on one side of the face of the wall shows sides of whole bricks, and being worked to the line on each face, the bricks on each bed, bond alternately over the course below; and so particular were they to having their bricks properly seasoned, that Vitruvius says, the inhabitants of Utica allowed no bricks to be used in their buildings that were not at least five years old, and also approved of by a magistrate; and the example of its application mentioned by him is that part of the wall at Athens towards Mount Hymettus and Pentilicus and the Temples of Jupiter and Hercules, in which the cells are of brick.

The remains of walls and buildings in Greece, executed with this artificial material, are so few at the present day, and so lightly described in the works of those scientific men who have visited that interesting country, that we are left in some doubt, whether they were used sun-dried or kiln-burnt, or both, as was the custom in Persia, Egypt, and other countries; for in the chapter, wherein Vitruvius mentions them, he does not state that they were burnt, but rather leads us to suppose they were made according to his rules. In that ill-fated city Pompeii,

"Far more than Sparta, this in Venus' grace,
"And great Alcides, once renowned the place."

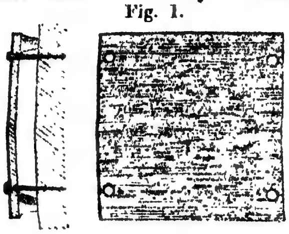
Wherein so much has been discovered relating to the architecture and the arts generally, and which indeed forms, as it were, the *link wanting* to connect our perfect acquaintance with the customs of Rome and Greece, the use of brick became a very necessary and useful appendage to their materials in building, and not only did the nature of the soil prove favourable for its manufacture, as did brick become of indispensable and universal service in the construction of their walls and buildings, forming, as it were, a bond to the shapeless pieces of rubble work of which they composed some of their walls, and giving solidity to others built of either squared volcanic stone, ferruginous scoria, and tufa; indeed, few of the public buildings of that city were erected without its application, and the eye of the traveller, upon first entering the forum, is struck with these buildings from the high dark masses of brick, contrasting with the verdant mountains at their back, and the low limy buildings around them.

The bricks are united together by mortar, or puzzolano, and in some of the walls it is found to be very bad. The thickness of the walls of houses very seldom exceed 18 inches, and is oftener less; their preservation, indeed, seems rather owing to the stucco on the surface, than the mortar used in building them.

The roof of the Basilica, or Court of Justice, the largest building in Pompeii, was supported by a peristyle of 28 Ionic columns, which are very

curiously constructed of bricks, moulded so as to form the volutes to the columns, the exterior of which was afterwards covered with cement; and here I must call your attention to a mode they had of forming a more perfect and dry wall, wherever the quality of the building rendered it necessary, or where they required a more perfect surface to paint upon; in the enclosure walls of the Peribolus of the Temple of Venus, and the wall in the public baths, the internal face is covered by a course of tiles fixed to it by ties or nails, and between which and the wall is a hollow space produced by four projecting feet on the back of the tiles; thus a circulation of air was kept up behind the tiles and the painted stucco, the face remaining uninjured by damp; a method which might be adopted at the present day instead of using battens to our walls, which are subject to the dry rot, affording in my mind a notion that the same would not be inapplicable to the purposes of ventilation.

Fig. 1.



Searching the remains of "the gorgeous palaces, the cloud-capp'd towers," of ancient Rome, we discover them handed down to us built with this almost imperishable material, brick, both *sun-dried* and *kiln burnt*; but most of the old houses of Rome were built with the first kind. They had several sizes of bricks, one of which they called bipeda, or two Roman feet long; another, didoron, about six inches broad and one foot long; in Palladio's time, artificial stone or bricks were called "quadrels," and, according to Pliny, those chiefly used were a foot and a half long and a foot broad, which also agrees with the size mentioned by Vitruvius, though Alberti says, "we see in some of their buildings, and especially in their arches, bricks, two feet every way," but he afterwards remarks, that in several of their structures, particularly in the Appian way, were several different sorts of bricks, some smaller and some bigger, and he mentions having seen some not longer than six inches, nor broader than three, and one inch thick; but these were chiefly used in their pavements and edgeways; and Palladio observes, bricks may be made bigger or smaller, according to the nature and quality of the building, and the use to which they are designed; they also made bricks of other forms than those enumerated. "I am best pleased," says Alberti, "with their triangular ones, which they made in this manner: they made one large brick a foot square and an inch and a half thick; while it was fresh, they cut it in two lines crossways from one angle to the other, which divided it into four equal triangles. These bricks had the following advantages: they took up less clay; they were easier to dispose of in the kiln and to take out again; they were more convenient for working, because the bricklayer could hold four of them with one hand, and with a small stroke divide the one from the other; when placed in the wall, they appeared like complete bricks of a foot long. Some of these bricks are to be seen in the walls of Rome, particularly that part built by the Emperor Aurelian."

From the Basilica of St. Paul.

And Hope speaks of bricks being made in the form of lozenges, and some were even moulded, or were, after being cemented together in regular layers, carved out into every variety of architectural ornament, as we see at Rome, in the remains of the Amtheatrum Castrense, of the Temple of the God Ridiculus, and in another building, where even the capital and foliage of the Corinthian order are cut out of solid masses of brickwork.

Capital at the Temple of the God Ridiculus.

Fig. 3.—Profile.

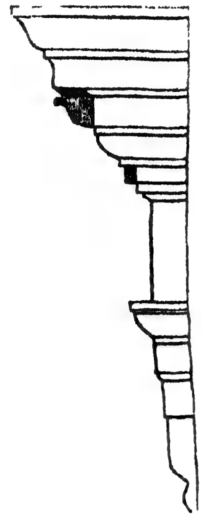

Fig. 4.—Elevation.

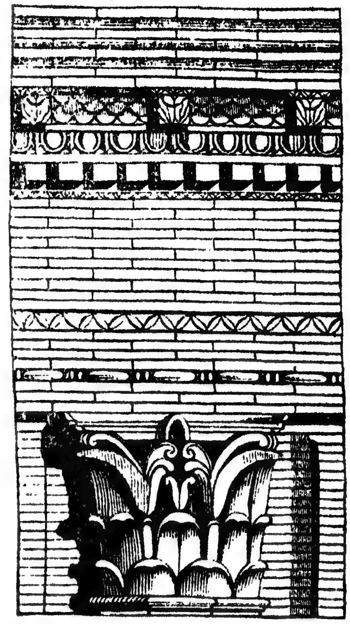

From these ancient examples of ornamental brickwork, may we trace the application of it to the various moulded fronts of houses, &c., subsequently erected in this and other countries. With regard to the method of manufacture, we learn from Vitruvius, that a red or chalky white earth, of a strong sandy nature, mixed with straw, was considered the best, on account of its not being heavy, which it was thought better to dig in the autumn, and make it into brick early in the spring; after they were moulded, they were placed in the shade to dry, and when made properly, they were not put into the kiln for two years afterwards. Alberti says, the ancients mixed marble with the red earth; and it was also customary for the Romans as well as the Egyptians to inscribe and impress their bricks with various devices. In the bigger sort, holes were left, that they might dry and burn better.

The height and thickness of the walls at Rome, anciently were, according to an old law, all built to a certain standard. Vitruvius says, no wall abutting on a public way was allowed to be more than one foot and a half thick; and Julius Cæsar, upon accounts of the mischief that might happen from bad foundations, ordered that no house should be more than one story high; and it is recorded that Augustus did account it a great commendation of himself, that having found Rome mostly built of brick, he left it of marble.

But when we view those vast remains of ancient splendour at the Palatine Mount, the aqueducts, baths, and temples, we must admit, that however much we may owe to the effect produced by the introduction of costly marbles, there was nothing wanted in the use of this material to produce the most powerful idea of strength and magnificence.

I have not sought for examples in those cities on the continent which owe their origin, or at least much of the rank they have since attained to the conquering hands of the Romans, but have transferred my inquiry to England,

"That pale, that white-faced shore,
Whose foot spurns back the ocean's roaring tides."

Fig. 5.

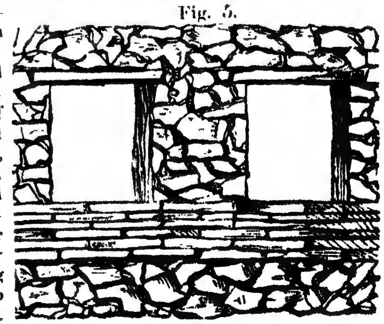

Fig. 6.

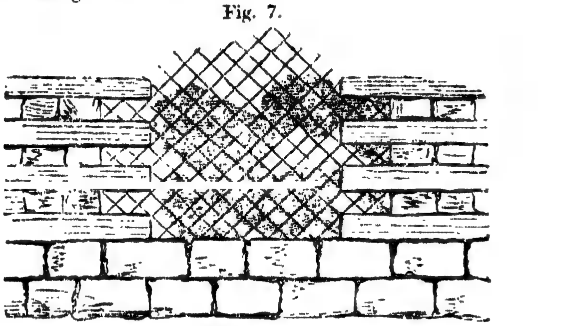
And here is attributed to the Romans their introduction, although the Britons might have been acquainted as well as the Gauls (and with whose country a correspondence subsisted) with the art of making bricks, both in the baked and unbaked form; but, however, it is only in the ancient Roman walls that we have the first record and example of their use in England, where they even then were very sparingly applied, being only inserted for the purpose of turning arches or in making bands to strengthen their other materials. These bands consisted of three or four courses of tiles laid through the wall, and were placed at two or three feet from each other, the intermediate space being built with cement, pebbles, and rag-stone, as fig. 5 and 6: in this manner, the walls of Verulam, Colchester, Chesterford, London, and other places, were built; and Stowe, in his account of the repair of part of London wall, gives the size of these bricks as measuring $17\frac{1}{2}$ inches long, $11\frac{3}{4}$ inches wide, and one inch and a quarter thick.

The Saxons and Normans, we find, continued to use bricks, and called their brickwork tigel; but it is rather uncertain whether they actually manufactured them, or collected them from the works erected by the Romans, for in most cases where they were used, their buildings were near some Roman station. The two churches at St. Alban's were built with the same sort of bricks; the one, St. Michael, built by the Saxons in the tenth century, and the Abbey Church, built by the Normans in the eleventh; but as it is found in the Abbey Church, some are moulded to form nowels, small round pillars, &c., &c. It is most probable, that the Saxons and Normans not only continued the practice of making them, but also deserve much credit for their ingenuity, in moulding them to other forms, as the intersecting arches to the west front of St. Botolph's Priory, in Colchester. How long the practice of making them the size of the Roman ones does not appear, but a change in the form began between the time of Henry the First and Edward the Second (1100 to 1307), when the Flemish manner of making them was introduced. However, the name of bricks was not universally adopted until the time of Henry the Sixth (1422). Wall tiles or bricks were used in some of the buildings belonging to the Priory of Ely, in the time of Edward the Second (1310), made in the Flemish manner, but of different sizes, being 12 inches long, 6 inches wide, and 3 inches thick; and others 10 inches long, 5 inches wide, and 2 inches thick. The price per thousand, in Edward the Third's time (1327), was from 6*s.* to 6*s.* 1*d.*, and they continued much at that sum, until the time of Richard the Second (1377), when they were sold at 6*s.* 8*d.*; at this period, Michael de la Pole, a rich merchant of Hull, erected a large house entirely of brick; and this, one of the earliest thus constructed, set the example for building in that style.

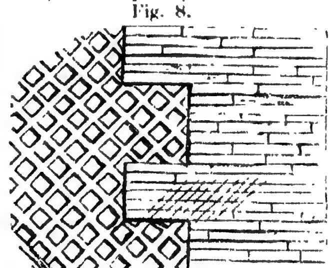
The peculiar method of building with them at this time was merely by facing the wall with brick, irregularly laid, in many instances, and in others in chequered patterns, with black flints, the foundations being formed with rag-stones. See fig. 7.

Fig. 7.



When a more perfect manner of constructing buildings, and its more general use divested it of much of its original irregularity, and towards the latter end of the reign of Henry the Seventh (1505), and beginning of that of Henry the Eighth, the mansions began to lose their castellated character, though still retaining many of its peculiarities. Layer Marney Hall, Essex, built in the time of Henry the Eighth, is a very good example. Chequered compartments of flints, diagonal lines of dark flagged bricks, were frequently introduced into the front of buildings about this period; and in 1530, Hans Holbein, the painter, built a gate at Whitehall, opposite the Banqueting-house, in this manner, with chequered brickwork, stone, and black flints, and ornamented the front with busts, in recesses. Buildings of a deep red brick, window reveals moulded in brick, and during the reigns of Mary and Elizabeth (1553—1558), the ornaments of Roman Architecture, were frequently introduced in brick, or baked clay, which laced the fronts of houses, and covered the shafts of chimneys, and continued in numerous fantastical shapes, until the reign of James the First (1603). Shortly after, they were laid aside. In this and the preceding reign, the walling was very bad, being mere rubbish, or even turf or peat, between two thin shells of brick. Inigo Jones introduced a better method, of which the piers in Lincoln's Inn-Fields are an excellent specimen; and Sir Richard Crispe, the patriotic friend of Charles the First, is said to have been the inventor of the art of making them as now practised. "In the year 1587," says Fuller, "began beautiful buildings in England, as to the generality thereof—whose homes were but homely before, are now most regular pieces of architecture."

Fig. 8.



The method adopted principally in these ages of building with brick was in what we term now English Bond, which was certainly well understood, and many durable examples of which still continue to adorn this country; but about the time of James, and for a long period after, a very careless method of erecting walls with brick began and continued; and although much is attributed to its perfection in the days of Inigo Jones, it does not appear, upon examination of several old buildings, that it was thoroughly understood and appreciated until some years after, when its peculiar advantages over wood, a very common method of building, began to present itself to the government of James the First; and accordingly we find a proclamation by him, March 1st, 1605, forbidding all increase of *all* new buildings within the city and one mile thereof, and likewise commanding all persons henceforth to build with either brick or stone; and another, Oct. 10, 1607, to the same purpose, when it appears that some were censured in the Star Chamber for building contrary to the tenor of the proclamation; and again, in 1614, all commissioners were required to proceed with strictness against offenders in this sort, "for from this time," says Stowe, "began the new reformation in building." But it was not until after the Great Fire of London that it attained universal adoption; and to the age of Sir Christopher Wren, and his immediate successors, must we feel indebted for some of the finest specimens, as far as regards neatness of workmanship, of which the entrance to the Middle Temple, and several fronts of houses about the city and west end of the town, are excellent examples, when the method, styled Flemish Bond, was introduced.

Its use, since then, has been unremittingly multiplied, together with the buildings in this vast city; for, according to Stowe, we find there were, in 1682, only 84,000 houses in the walls of the city, the borough of Southwark, and city and liberties of Westminster; and in 1831 we find the number more than doubled, being no less than 185,000. In 1834, duties were paid upon 1180 millions of bricks; and I find, in 1835, the amount of duty paid on bricks amounted to no less a sum than 395,030*l.* 7*s.* 8¾*d.*

I shall not take up your time further with descriptions of the various purposes to which it is at the present day applied, although I think much benefit and amusement might be afforded in so doing, but hope some more able member will take up the subject and supply the deficiencies, of which, I doubt not, there are many occurrences here.

In concluding, I beg to return many thanks for the kind attention the Society have favoured me with in this my attempt to illustrate the antiquity and application of so useful a material, which to this period composes alike the walls of the monarch's palace and the peasant's dwelling.

MEETINGS OF SCIENTIFIC SOCIETIES.

Institution of Civil Engineers, 1, Cannon-row, Westminster, every Tuesday Evening, at 8 o'clock.

Royal Institute of British Architects, 16, Grosvenor-street, Grosvenor-square, Monday Evening, 8 o'clock, January 15th and 29th.

Architectural Society, 35, Lincoln's Inn-fields, Tuesday, January 2nd, 16th, and 30th.

Society of Arts, Adelphi, every Wednesday, 8 o'clock; Illustration, Tuesday, January 9th.

PARLIAMENTARY PROCEEDINGS.

House of Commons.—For the Session 1837-8.

Nov. 21.—Private Bills.—Standing Order [18th June, 1811] read:—Resolved, "That this House will not receive any Petition for Private Bills after Friday, the 16th day of February next." Resolved, "That no Private Bill be read the first time after Monday, the 26th day of March next." Resolved, "That this House will not receive any Report of such Private Bill after Monday, the 11th day of June next."

Nov. 22. Petitions for Private Bills.—Select Committee appointed, "to whom all Petitions for Private Bills are to be referred, except those for making any Turnpike Road, or to continue or amend any Act for making, maintaining, keeping in repair, or improving any Turnpike Road." Mr. Aglionby, Mr. Baines, Mr. Bingham Baring, Mr. Bell, Mr. Bowes, Mr. Bramston, Sir John Yarde Buller, Mr. George Cavendish, Mr. Chalmers, Lord Viscount Clements, Mr. Robert Clive, Mr. Compton, Mr. Gibson Craig, Mr. Crawford, Mr. Dunlop, Lord Viscount Eastnor, Mr. Tatton Egerton, Captain Gordon, Mr. Greene, Mr. Halford, Major Handley, Mr. Hodges, Mr. Henry Thomas Hope, Captain Jones, Mr. Hope Johnstone, Mr. Shaw Lefevre, Mr. Mildmay, Mr. Morgan John O'Connell, the O'Connor Don, Mr. Robert Palmer, Mr. Pease, Mr. George Philips, Mr. Poulter, Mr. Sanford, Mr. Stansfield, Mr. Villiers Stuart, Mr. Strutt, Sir Charles Style, Sir Harry Verney, Mr. Wodehouse, Lord Worsley, Mr. Wrightson.

Standing Orders.—Select Committee appointed, "to whom shall be referred all Reports from Committees on Petitions for Private Bills, in which it shall be stated that any of the Standing Orders of this House have not been complied with, and to report their opinion thereupon from time to time to the House."—Lord Viscount Clive, Lord Viscount Ebrington, Mr. Estcourt, Sir Thomas Fremantle, Mr. Montagu Chapman, Sir Edward Knatchbull, Mr. Wilson Patten, Mr. Pendarves, Sir Robert Price, Lord Viscount Sandon, Sir George Strickland, Sir Matthew Wood, Mr. George Wilbraham, Mr. William Miles, Mr. Pringle. Power to send for persons, papers, and records, five to be the quorum.

Nov. 21.—Margate Improvement. Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Nov. 27.—Railroads.—Select Committee appointed, "to consider the present state of the communications by Railroads, so far as it affects the regularity and convenience of the transmission of Letters, and the Post Office in general; to ascertain on what terms Mails are now conveyed by the Railroads in operation, and what measures it may be just and expedient to adopt for the purpose of securing to the public, in future, the benefit of the conveyance of the Mails by Railroads."—Mr. Baring, Mr. Wallace, Mr. Labouchere, Lord Viscount Lowther, Mr. Gillon, Lord Viscount Sandon, Mr. Hutton, Mr. Scholefield, Mr. Greene, Lord Seymour, Mr. Easthope, Lord Granville Somerset, Lord Charles Fitzroy, Sir Robert Fergusson, Mr. Loch. Power to send for persons, papers, and records, five to be the quorum.

Nov. 28.—Railroads. Petition of Thomas Parkin, praying for an Act appointing a Board of competent persons to inspect all Railroads previous to their being used, who shall certify the same as safe and fit for use; to lie on the table.

Nov. 29.—Patents for Inventions.—Bill to amend the Law of Patents, and to secure to individuals the benefit of their inventions, ordered to be brought in by Mr. Mackinnon and Mr. Baines.

Nov. 30.—Railway Colonnades.—Petition of Robert Thomas Webb, suggesting a Plan for erecting Railway Colonnades over the Foot-pavements of London, and praying the appointment of a Committee to inquire into its merits; to lie on the table.

Dec. 4.—Newcastle-upon-Tyne and Carlisle Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 4.—Thames Improvement Company and Drainage Manure Association.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 4.—Houses of Parliament.—Bill to enable the Commissioners of Her Majesty's Woods and Forests, Land Revenues, Works, and Buildings, to purchase ground and tenements required to complete the site for the New Houses of Parliament, ordered to be brought in by Mr. E. J. Stanley and Mr. Baring

Dec. 4.—Government Architects.—Address for "Return of the names and dates of the appointments of the several Architects now employed by the Commissioners of Woods and Forests, or by any other department of the Government, to prepare plans, and to superintend the erection or repairs of public buildings; stating the amount of salary, if any, which each receives for that duty, and the rate per cent. allowed on the expenditure as commission for said duties; stating also the regulations under which the public works are conducted by the Government Architects in England."

"Also, a Return of the amounts paid to each Government Architect for salary, for plans, and for superintending the works, and what works, stating the rate per cent. allowed, and the amount of the gross expenditure for each work, in each year since 1820, in England."

"Similar Returns for Scotland and for Ireland."

Dec. 5.—Milton-next-Sittingborne Improvement. Petition for Bill reported, and Bill ordered to be brought in by Sir Edward Knatchbull and Mr. Plumptre.

Dec. 7.—Anti-Dry Rot Company.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 7.—Houses of Parliament Bill.—Read 2d; and committed for this day

Dec. 8.—Houses of Parliament Bill. Petition of Owners and Occupiers of Houses in Abingdon-street, Westminster, for alteration; to lie on the table

Dec. 8.—Houses of Parliament Bill.—Order for Committee read, and discharged.—Bill committed to Mr. Edward John Stanley, Lord Viscount Lowther, Colonel Evans, Mr. Byng, Mr. Charles Wood, Mr. Leader, Lord Granville Somerset, Sir Matthew Wood, Mr. Gally Knight, Mr. Moore O'Ferral, Mr. Thomas Wood, Captain Ellice, Mr. Hume; five to be the quorum. Petition from Abingdon street presented this day; referred.

Dec. 8.—Houses of Parliament.—Copy or Abstract ordered, "of the Tenders delivered by Builders for the Embankment and the Terrace, and a portion of the Foundation of the Buildings of the Houses of Parliament; and stating which of them have been accepted.—Also, an Abstract of the estimates made by Messrs. Walker and Burge, engineers, and Mr. Barry, the architect for the same works, as approved of, and confirmed by, the Surveyors of the Office of Woods and Works, and contained in the Report made by the Commissioners of the Woods and Works, and laid on the table of the House of Commons."

Dec. 11.—London and Greenwich Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 13.—Patterns and Inventions.—Bill to encourage the advancement of the Arts by securing to individuals the benefits of their Patterns and Inventions for one year, ordered to be brought in by Mr. Mackinnon and Mr. Baines

Dec. 14.—Margate Improvement.—Petition for Bill reported, and Bill ordered to be brought in by Sir Edward Knatchbull and Mr. Plumptre.

Dec. 14.—Necropolis Cemetery.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 15.—Thames Improvement Company and Drainage Manure Association.—Petition for Bill reported, and Bill ordered to brought in by the Earl of Euston and Mr. Wilberforce.

Dec. 15.—Houses of Parliament Bill. Reported, and recommitted for to morrow.

Dec. 16.—Houses of Parliament Bill. Considered in Committee, and reported, with an Amendment; Amendment agreed to; Bill to be read 3rd time on Monday next.

Dec. 18.—Milton next Sittingborne Improvement Bill, "for better paving, cleansing, lighting, watching, and otherwise improving the town of Milton-next-Sittingborne, in the county of Kent;" presented, and read 1st time; to be read 2nd time.

Dec. 18.—Houses of Parliament Bill. read 3rd time, and passed

Dec. 19.—Houses of Parliament.—Abstract presented of Tenders for Embankment, &c. of the New Houses of Parliament [ordered 8th of December]; to lie on the table.

Dec. 21.—Saltash Floating Bridge.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 21.—Union Workhouses.—List ordered, "of the Unions for which Work houses have been ordered by the Poor Law Commissioners to be built, purchased altered, or enlarged, from the passing of the Poor Law Amendment Act to the present time, with the number of persons to be provided for, the amount authorized to be expended, and the names of the Architects and Contractors."

Dec. 21.—Metropolis Improvements.—Select Committee appointed, "to consider and report to the House the best means of carrying into effect the Improvements in the Metropolis, as reported by the Select Committee in the Session of 1836." Sir Matthew Wood, Mr. Chancellor of the Exchequer, Sir Robert Peel, Lord Viscount Lowther, Mr. Herries, Admiral Codrington, Sir Robert Harry Inglis, Mr. Shaw Lefevre, Mr. Wakley, Colonel Evans, Mr. Clay, Mr. George Palmer, Mr Pendarves, Mr Barnard, Mr. Hall. Power to send for persons, papers, and records; five to be the quorum:—Report from Committee [2d August, 1836] referred to the Committee.

Dec 21.—Public Monuments.—Return ordered, "of the number of Monuments erected in Westminster Abbey and St. Paul's at the public expense, from the year 1750 to the present time; specifying the names of the persons to whose honour they were erected, and the sums paid for each; with the aggregate amount."

Dec. 21.—Houses of Parliament.—Abstract of Tenders for Embankment, &c. [presented 19th December] to be printed.

Dec. 22.—Paington Harbour Bill.—"for making and maintaining a Harbour and other Works at Paington, in the county of Devon;" presented, and read first time; to be read second time.

Dec. 22.—London and Croydon Railway (No. 1)—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Dec. 22.—London and Croydon Railway (No. 2)—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

House of Lords.—The following are the resolutions adopted by the House of Lords regarding Private Bills: "Ordered, that the House will not receive any petition for a private bill after Tuesday, the 20th day of March next. Ordered, that the House will not receive any report from the judges, upon petitions presented to the House for private bills, after Monday, the 30th day of April next. Ordered, that the said orders be printed and published, and affixed on the doors of the House and Westminster Hall."

LIST OF PATENTS GRANTED BETWEEN THE 2nd AND 23rd DECEMBER, 1837, BOTH INCLUSIVE.

James Dowie, of Frederick Street, Edinburgh, Boot and Shoe Maker, for his invention of "Certain Improvements in the Construction of Boots and Shoes or other coverings for the Human foot."—2nd December; 6 months.

William Occleshaw, of Manchester, in the county of Lancaster, Leaden Pipe Manufacturer, for his invention of "Certain Improvements in the Machinery or Apparatus for Manufacturing Pipes or Tubes, or other similar articles from Lead or other Metallic Substances."—2nd December; 6 months.

Thomas William Booker, of Merlin Griffith Works, Glamorganshire, Iron Master and Tin plate Manufacturer, for his invention of "Improvements in preparing Iron to be coated with Tin or other Metals."—4th December; 6 months.

George Cottam, of Winsley Street, Oxford Street, in the county of Middlesex, Engineer, for his invention of "Improvements in the Construction of Wheels for Railway and other Carriages."—5th December; 6 months.

Moses Poole, of the Patent Office, Lincoln's Inn, in the county of Middlesex, Gentleman, for "Improvements in Looms for weaving Figured and Ornamented Fabrics, being a communication from a foreigner residing abroad."—5th December; 6 months.

Moses Poole, of the Patent Office, Lincoln's Inn, in the county of Middlesex, Gentleman, for "Improvements in Printing, being a communication from a foreigner residing abroad." 5th December; 6 months.

John Hall, of the town of Nottingham, in the county of Nothingham, Lace Manufacturer, for his invention of "Certain Improvements in Machinery, whereby Cloth or woven Fabrics of various kinds may be extended, or stretched, and dried in an extended state." 5th December; 6 months.

Joshua Taylor Beale, of Church Lane, Whitechapel, in the county of Middlesex, Engineer, for his invention of "Certain Improvements in, and additions to his former invention, known by the title of a Lamp, applicable to the burning of substances not hitherto usually burned in such vessels or apparatus, and secured to him by Letters Patent, dated 4th February, 1834."—7th December.

Samuel Mills, of Darleston Green, Iron and Steel Works, near Wednesbury, in the county of Stafford, Iron Master, for his invention of "Improvements in Machinery for Rolling Metals." 9th December; 6 months.

Jeremiah Bynner, of Birmingham, in the county of Warwick, Lamp Manufacturer, for his invention of "Improvements on Lamps." —9th December; 6 months.

Benjamin Cook, of Birmingham, in the county of Warwick, Brass Founder, for his invention of "An Improvement in Gas Burners, commonly called or known by the name of Argand Burners."—9th December; 6 months.

Cornelius Ward, of Great Titchfield Street, Mary-le-bone, in the county of Middlesex, Musical Instrument Maker, for his invention of "Improvements on the Musical Instruments designated Drums."—9th December; 6 months.

Thomas Vale, of Allen Street, Lambeth, in the county of Surrey, Coach Joiner, for his invention of "Improvements in Hinges."—13th December; 6 months.

James Hunter, of Leys Mill, Arbroath, in the county of Forfar, Mechanic, for his invention of "A Machine for Boring or Perforating Stones." 13th December; 6 months.

William Elliott, of Birmingham, in the county of Warwick, Button Manufacturer, for his invention of "Improvements in the manufacture of covered Buttons." —14th December; 6 months.

Thomas Joyce, of Camberwell New Road, in the county of Surrey, Gardener, for his invention of "Improved Apparatus for Heating Churches, Warehouses, Shops, Factories, Hot houses, Carriages, and other Places requiring Artificial Heat, and improved Fuel to be used therewith."—16th December; 6 months.

Joshua John Lloyd Margary, of Wellington Road, St. John's Wood, in the county of Middlesex, Esq., for his invention of "A New Mode of Preserving Animal and Vegetable Substances from Decay."—19th December; 6 months.

John Gray, of Liverpool, in the county of Lancaster, Engineer, for his invention of "Certain Improvements in Steam-Engines and Apparatus connected therewith, which Improvements are particularly applicable to Marine Engines for Propelling Boats or Vessels, and part or parts of which Improvements are also applicable to Locomotive and Stationary Steam Engines and other Purposes."—19th December; 6 months.

Edmund Butler Rowley, of Charlton upon Medlake, in the parish of Manchester and county of Lancaster, Surgeon, for his invention of "Certain Improvements applicable to Locomotive Engines, Tenders, and Carriages, to be used upon Railways, and which Improvements are also applicable to other Useful Purposes."—19th December, 6 months

John White, of Manchester, in the county of Lancaster, Engineer, for his invention of "Certain Improvements in Apparatus usually employed in Lathes for Turning Metals and other Substances."—19th December; 6 months.

James Berington, of Winchworth Place, St. Leonard's, Shoreditch, Gentleman, and Nicholas Richards, of Camomile Street, in the city of London, Builder, for their invention of "Certain Improvements in Curing or Preventing Smoky Chimneys, which Improvements are also applicable to the purposes of Ventilation."—19th December; 6 months.

Christopher Nickels, of Guildford Street, Lambeth, in the county of Surrey, Gentleman, and Henry George Collins, of Queen Street, Cheapside, in the city of London, Bookbinder, for his invention of "Improvements in Bookbinding, parts of which Improvements are applicable to the Cutting Paper for other purposes."—19th December; 6 months.

John Robertson, Jun., formerly of Tweedmouth, Berwick, but now of Great Charlotte Street, Buckingham Gate, in the county of Middlesex, Gentleman, for his invention of "Improvements of Architecture, as regards its Construction, or in the Description or Properties of the Forms and Combinations, and also of the Superficial Figures which may be employed; the Application of these Improvements, or of the Principles or Method thereof, being also for supplying Forms, Figures, or Patterns, in various Arts or Manufactures; also for an Improvement or Improvements with regard to the Surfaces of Buildings, whether Interior or Exterior, for Protecting them from Decay, and also giving them a more Finished Appearance."—19th December; 6 months.

William Henry Pitcher, of the West India Dock House, Billiter Square, in the county of Middlesex, Merchant, for his invention of "Improvements in the Construction of Docks, and Apparatus for repairing Ships and Vessels."—19th December; 6 months,

N[illegible] Clay, of West Bromwich, in the county of St[illegible], M[illegible] Chemist,

for his invention of "Improvement in the Manufacture of Iron."—19th December; 6 months.

William Sandford Hall, of Streathearn Cottage. Chelsea, Lieutenant in the Army, for his invention of "Improvements in Paddle Wheels."—19th December; 3 months.

the means of communicating intelligence by signals."—22nd December; 6 months.

Charles Button, of Holborn Bars, Chemist, and Harrison Grey Dyar, of Mortimer Street, Cavendish Square, Gentleman, both in the county of Middlesex, for their invention of "Improvements in the Manufacture of White Lead."—23rd December; 6 months.

William Bundley, of Birmingham, in the county of Warwick, Patent Paper Tray Manufacturer, for his invention of "Improvements in the Construction of Presses."—23rd December; 6 months.

William Losh, of Benton Hall, in the County of Northumberland, Esquire, for his invention of "Improvements in decomposing Muriate of Soda, (Common Salt), parts of which Improvements are also applicable to the condensing Vapours of other processes."—23rd December; 6 months.

Jehiel Frankling Norton, of Manchester, Merchant, for "Certain Improvements on Stoves or Furnaces; being a communication from a foreigner residing abroad;" 23rd December; 6 months.

John Elvey, of the city of Canterbury, in the county of Kent, Millwright, for his invention of "Improvements in Paddle-Wheels," 23rd December; 6 months.

STEAM NAVIGATION.

Havre.—On the 24th November last was embarked from this port for Hamburgh, all the machinery for the engines of two steam boats, built in Belgium, to commence the operations of the Company established for navigating the river Meuse. A house of this place (Messrs. Durosselli and Co.) has been placed at the head of this company: present appearances of success are most favourable, as there are, in the course of the river Meuse, a great number of populous towns. The two boats will commence service next spring; they will be propelled by steam engines of thirty horse power, are calculated to carry at the least 150 passengers, and will not draw more than 20 inches of water. The engines, including water in the boiler, will not weigh more than 18,000 kilogrammes (39,677 lbs. English). The engines were manufactured by Mr. John Cockerill of Seraing, who also furnished those for the Tagus steam-boat. This is the first time that machinery for steam-boats have been constructed in our port for foreigners: it is expected that this new branch of industry will be attended with the best success, and that it will preserve to the port of Havre that superiority for which it has been hitherto distinguished.

A new steam ship, named the *Tagus*, was launched on the 30th of November last, in this port. She is the largest and best that has been constructed in France: the tonnage of this superb boat is 600 tons, she is to navigate between Havre, Vigo, Oporto, Lisbon, and Cadiz: it is calculated that she will (although touching at Vigo and Oporto) perform her voyage to Lisbon in 90 hours, and to Cadiz in 120 hours. She is to carry 150 tons of coal, and 200 tons of merchandise, besides accommodation for 100 passengers. Her engines were manufactured by Mr George Cockerell, and are equal to 172-horse power; they are constructed on a new system, and will not consume more than 800 kilogrammes (1,763 pounds English) of coal per hour, without merchandise, she can take sufficient fuel to last fifteen days. A new plan has been adopted in fitting up this ship, conformably to the wants of the country which she is destined to visit; instead of a single chamber, surrounded with cabins, there will be a dining room and a spacious saloon, where the passengers can repose during the heat of the day. She is the second steam-ship which has been launched in the port of Havre within the last few days. the two are reckoned to be the finest steam boats in France.

Steam Navigation for Long Voyages.—A proposal has been made for shortening the communication with New South Wales, by steam communication with Acapulco to Vera Cruz, touching at Otaheite for coals, by means of which the voyage might be accomplished within fifty days. A plan by which the whole course might be completed in from sixty five to seventy days is by way of the proposed steamers to Jamaica, and thence, through Panama, to Lima and Chili, from the latter of which an extensive intercourse is carried on with Australia in wheat.—*Courier.*

Steam v. Draught Power.—Two new vessels have been launched, the *Wilberforce* and *Seahorse*, for the Hull and London stations, which are to perform the distance in 18 hours, for 5*s*. Coaching between Hull and London is 1*l*. 10*s*. outside, and for the last month, it has taken, upon an average, 23 hours to do the journey. In the one case the passengers are exposed to the atmosphere day and night, in the other they are snugly ensconced in a warm and convenient room. The coach fare from Lincoln to London is now 1*l*. 8*s*. outside by the night coach, and the journey takes 18 hours. *Lincoln Gazette.*

Advancement of Science in Steam Navigation.—It is with pleasure we lay before our readers an account of the trials of the *William Wilberforce* steamer, which took place before she proceeded to Hull, to the great satisfaction of a number of scientific gentlemen who witnessed the performance of the engines. Nothing could surpass the beautiful style in which the vessel passed down the Thames, the engines performing in a manner beyond the expectation of every one on board. The *Wilberforce* is commanded by Captain Wilkinson, and belongs to the spirited and enterprising gentlemen forming the Humber Union Steam Company, and is for the conveyance of passengers, &c., between Hull and London. That which gives to the engines of this vessel a great superiority, and an immense additional power, is the application of Mr. Samuel Hall's, of Basford, patent condensers, which are becoming generally applied to first rate steam-vessels, and which no doubt, ere long, will be found in every steam-packet of importance. On both of the above occasions, the barometer indicated a vacuum in one engine of 29⅝ inches of mercury, and in the other of 29⅝ inches, the engines making 21 strokes of six feet per minute. The advantages attending Mr. Hall's patent condensing engines in heavy gales and storms at sea are quite surprising, for it matters not how hard it blows or how heavy the sea rolls, the same uniform power is maintained as in a calm; and while common engines, under similar circumstances, cannot keep up the vacuum to a higher point than from 20 to 25 inches, the patent engines obtain a steady vacuum of from 29 to 29¾ inches. The cause of this superiority is very obvious. In the common condensing engine, the steam is condensed by a jet of cold water coming in contact and mixing with it, the whole having to be removed by means of the air-pump—the quantity varying from five to seven gallons per horse-power per minute. Now, it is well known to practical engineers, that if so much water were injected as to keep the common engine up to its full power in a rough sea, it is highly probable that the engine would break down, and that the vessel would be greatly endangered; because, in a rough sea,

brought up almost to a stand; and as the injection is pouring in as rapidly when the engines are going at a slow as at a quick speed, the engines will be brought up altogether, or a breakage takes place, unless the injection water be reduced much below the average quantity required to keep a sufficient vacuum. No such danger or difficulty can take place with Mr. Hall's patent engines; for he condenses through the medium of metallic surfaces, whereby the condensing water from the sea never comes in contact with or mixes with the steam. The quantity of sea water required to be injected in a pair of common marine engines equal to those of the *Wilberforce* (viz., 300 horse power) is about 1,800 gallons per minute, which has to be pumped out of a vacuum by the air pump, whereas Mr. Hall's engines aboard the *Wilberforce* have only twenty gallons per minute requiring pumping out of a vacuum by such pump. There are many other important advantages resulting from Mr. Hall's patent invention, such as the much greater durability of the boilers, owing to their being supplied with pure distilled instead of sea or dirty water, in consequence of which the saline and earthy deposits, which must inevitably take place in common engines, are avoided. A great saving of fuel is the result of thus working with clean boilers, which never require blowing out, and the consequence is, additional room for the stowage of goods in proportion to the reduced quantity of fuel required. A great many more advantages are consequently obtained, but we will confine ourselves to adding those of the avoiding of the well-known nuisance of muddy water from the boilers being frequently showered over the passengers, and of the utter impossibility of an explosion taking place from want of water in the boilers.—*Correspondent of the Hull Observer.*

PROGRESS OF RAILWAYS.

Arbroath and Forfar.—Three parts of this railway are already finished. It is expected that in May next it will be partially at work, and that in August, at the latest, it will be in full operation.

Edinburgh, Leith, and Newhaven Railway.—We are authorized to state, that this undertaking is progressing rapidly, above 400 yards of the deepest cutting have been completed, and upwards of 50,000 cubic yards of earth excavated.

Edinburgh and Dalkeith Railway.—(Main line 10¼ miles long; branches 6½ miles.) The original object of this railway was to open a better and cheaper communication than previously existed between collieries and limestone quarries in the district through which it passes, and the Scottish capital, as well as the port of Leith; but so much has it been resorted to by passengers, that since the opening of it up to the 11th instant inclusive, there have been no less than 1,406,932 persons conveyed by it; and of this vast number *three only* met with serious injuries, from which, however, they ultimately recovered.

Eastern Counties. The works of this railway are now pushed as far as Ilford, and it is confidently expected that it will be opened to that town (seven miles) next summer. The Lea Bridge, Stratford Viaduct, Mill Pond and Abbey River Bridges, of five arches, are all completed, with the exception of the parapets, which will not be added till time have been allowed for the usual settlement of the masonry and brick-work. The Stents Mill, Angel Lane, and Maryland Point Bridges, are also fast advancing to completion; and last week, preparations were commenced for the erection of the only two other bridges of consequence on this side of Ilford, namely, those over the Aldersbrook and the Roding. *Railway Times.*

Great Northern Railway.—The Directors of this noble undertaking have already contracted, on very advantageous terms, for the execution of that part of the line extending from the much celebrated Stockton and Darlington Railway to Birkby, a distance of about eight miles; and that they have, in like manner, concluded a contract for the erection of a bridge over the river Tees, at Croft, a work of considerable magnitude: thus giving earnest to the shareholders of their determination to proceed with vigour, in order to a speedy completion of this connected link, so much needed to unite the North of England and Scotland with the southern counties, by means of the York and North Midland, North Midland, Midland Counties, &c. &c. railways, all expected to be in simultaneous operation at no remote period, so as to communicate with the Grand Junction, and London, and Birmingham railways. From all the data in our possession relative to this great national railway, we cannot help congratulating such of our readers as happen to possess an interest therein on the certain prospect now before them of ultimately deriving most ample remuneration on their capital so invested, more especially when we find that the Grand Junction Railway, which cost so much more than the Great North of England will do, is likely to pay to the fortunate shareholders a dividend at the rate of *twelve* per cent. per annum for the first six months. What this admirably managed undertaking will realize to the shareholders, when the London and Birmingham line and its other tributaries shall come into full operation, it is impossible to calculate with any degree of precision.—*Liverpool Journal.*

Grand Junction Railway.—It is said that the Post office Department have concluded a valid agreement with the Directors, which will enable the inhabitants of Liverpool, after the first of May next, to receive their London letters, dispatched on the preceding evening, at eight o'clock on the following morning.—*Standard.*

Grand Junction Railway.—Notice has been given, that it is intended to dispatch a train from the station in Lime-street, on Tuesday next, for the conveyance of pigs to Birmingham, which will be continued every Tuesday, Wednesday, and Thursday. This accommodation will open a new field of traffic to the dealers in Irish pigs, the increase and improvement in this stock having been very great of late. Hitherto the arrivals from Ireland have been principally taken to Manchester and some parts of Yorkshire.—*Liverpool Times.*

Lancaster and Preston.—The whole of the line of Railway has been re-measured and some slight variations and improvements have been determined on.—*Lancaster Guardian.*

North of England.—The contract for the formation of about eight miles of this Railway south of Darlington, was let on the 31st ult., the works of which will be commenced forthwith.—*Hull Advertiser.*

Sheffield, Ashton-under-Lyne, and Manchester Railway.—We are authorized to state, that the above undertaking is in a progressive and daily improving state, and that operations will be commenced early in the spring. The statement which has appeared in several of the papers, relative to its abandonment, is totally without foundation.—*Manchester Guardian.*

Whitby and Pickering Railway.—A great increase has taken place in the tonnage amount of traffic and number of passengers conveyed on this line during the last half year, the increase in the latter being 8,000, and the former 6,000 tons over the previous half-year.—*Hull Packet.*

London and Birmingham.—On the 1st of January next, the London and Birmingham Railway will be open as far as Stoney Stratford, and also the Birmingham end as far as Rugby, making in the whole 77 miles of this great undertaking completed.

Lancaster and Glasgow.—At the Penrith meeting on Tuesday week, the Earl of Lonsdale in the chair, Mr. Brockbank, in alluding to the western line over Morecambe Bay to Whitehaven, said, tha Mr. Stephenson had made a mistake of fourteen miles in computing the length of the line by the coast. He stated it would be eighty-eight miles, whereas in point of fact it would be one-hundred and two. The distance from Lancaster to Ulverstone was twenty-two miles, to Whitehaven, from the latter place, was forty-one, and Carlisle was thirty-nine from Whitehaven; and, upon a moderate computation, the error in the cost would amount to 200,000*l.* The expense of embanking twenty miles of sand would be enormous, far exceeding the cost of the formation of a tunnel, which would occur on the inner line. M. Brockbank further suggested, that a line might be adopted seven miles longer than that over Shap Fells, but thirty miles shorter than the coast line. There would be no tunnelling or cutting of consequence on this line. It appears that the line recommended by Mr. Brockbank will go within eight miles of Kendal, while the coast line would, at the nearest point, be sixteen miles distant.—*Lancaster Guardian.*

Bolton and Preston Railway.—This line of Railway seems to be at length determined upon, and is likely to be commenced in good earnest, and completed with success. The principal obstacle in its way is the high ground, a mile to the north of Chorley, under which, and the turnpike road, it will pass by a tunnel above a third of a mile in length, and at a depth of seventy-two feet from two of the summits on the surface. It had, however, been long ago ascertained that the material below consisted partially of loamy gravel, but for a considerable length under the highest part, of a bank of dry and solid marl, to a depth of one hundred feet. The borings which have been made on the south east side of the hill, corroborate former observations, and the writer of this article is confident that the north-western slope will be still more favorable. At all events, by keeping only fifty yards still more to the north, favourable results would be quite certain. This, however, would lead the projected line too far from entering the North Union Railway to advantage, with which it is intended to form a junction, a short distance from Rose Wittles. The above is only a cross line of communication betwixt the two rail roads, of about two miles and a half in length. That which is more direct to Preston, and perhaps to Blackburn, will afterwards, we understand be proceeded with.—*Preston Observer.*

London and Birmingham Railway.—The works of this great undertaking are proceeding most favourably—the worst points, viz., at Kilsby and Blisworth, being now quite under command. One hundred and fifty yards of the Kilsby tunnel were completed last month, and one hundred and seventy four the month preceding, leaving on the 5th instant only seven hundred and fifty six yards to accomplish. There is every reason to anticipate that the whole line will be open for traffic by the 1st of next October.—*Railway Times*

Uxbridge and Staines Junction.—The newly projected collateral line of railroad, called the "Grand Western Uxbridge and Staines Junction Railway" (plans of which have been forwarded to the different parishes, through which it is intended to pass, some months since), is intended to be introduced to the notice of Parliament as early in this session as possible. The bill, when obtained, is to be put into operation as quickly as possible.—*Aylesbury News*

FOREIGN RAILWAYS.

Austrian.—The railroad near Vienna called *Kaiser Ferdinand's Nordbahn*, or the Emperor Ferdinand's North way, was partially opened on the 23d of November, from Florisdorf to Wagram, a distance of one German mile and three quarters, or about eight English miles. An immense crowd, including all the fashionable world of Vienna, assembled to witness the novel and interesting spectacle. A train of eight passenger carriages was formed, some conveying eighteen, and others twenty-four, the whole train one hundred and fifty individuals, and attached to a locomotive machine of thirty-horse power. The locomotive, which was ordered from England, arrived at Vienna some months ago, and has since been a great object of curiosity to all the engineers and mechanicians of the capital, who express the most unbounded admiration of its construction. The passenger-carriages were, we believe, of native make, and are highly praised for their luxurious elegance. At ten o'clock precisely the whole train moved off, to the enthusiastic delight of the spectators, and safely arrived at Wagram in twenty six minutes, where it was turned round, and guided back to Florisdorf. The whole affair went off to the satisfaction of all parties. It is anticipated that early in December, the line will be practicable as far as the Prater itself, the gigantic bridge over the great branch of the Danube being now nearly completed.

Dutch.—A pamphlet by Mr. Donker Curtius, in favour of the extension of railways in Holland, has met with an opponent in the person of Mr A. F. Bouricius, "Royal Prussian Titular Postmaster at Arnheim." Mr Bouricius, in his pamphlet on the subject, even declares himself opposed to the railway already begun between Amsterdam and Haarlem, observing, that "in commerce Amsterdam is now no more a Liverpool, than Haarlem is a Manchester." He considers that injury will be done to the capital already embarked in canals, treckschuyts, &c., and no counterbalancing advantages obtained by a mere increase in the speed of internal communications, the probable profits of which, in Holland, he regards as totally inadequate to reimburse its promoters. We can only observe, that the circumstances of Holland, with regard to canals, are certainly so peculiar, as to render the new improvement of less convenience to them than to any other state; but it would be a most singular spectacle, if, while almost all Europe is eagerly pressing forward to reap the advantages of this great discovery, and the thinly-peopled States of America, one of its richest, most industrious, most commercial, and most thickly-peopled communities, were to remain inactive.

French.—Operations are carrying on with activity on the railroad from Montpellier to Cette. The road through the morasses of Vic and Frontignan is already marked out, and that through the piece of water called the "Pond of Ingrill," begun. The works are under the direction of an English engineer, Mr. Thomas Brunton. A railroad is projected from Montpellier to Nismes.

Italian.—The works are begun on the railroad from Naples to Castellamare. The shares of this undertaking are 1,000 Italian *lire* each, or about 40*l.* sterling, each *lira* being equal to a French franc, or nearly tenpence English. The whole capital comprises eleven thousand of these shares, or eleven million of *lire*, about 440,000*l.* There is a great difference of opinion at Naples as to whether the undertaking will ever pay; but, we believe, little difference of opinion any where else.

Prussian.—The Royal permission, or "concession," as it is technically called, for the formation of a railway from Magdeburgh to Leipzig, was received at Magdeburgh, on the 24th of November, together with the law of expropriation, or permission to take possession of private landed property for the purposes of the railway, on the payment of an adequate compensation awarded to the proprietors, in the same manner as in the use of high roads made by Government. This permission is clogged with conditions, one of which is, that after the expiration of thirty years, the Government is to be at liberty to take possession of the whole concern, paying a compensation to the then existing shareholders—a measure which, of course, is certain to be adopted in case the undertaking should prove successful. Another is, that at the expiration of ninety years, the railway becomes unconditionally the property of the State. The new railroad is to pass through Kothen and Halle to Leipzig, where, by the time it is completed, it will find that from Leipzig to Dresden in full operation.—*Railway Times.*

Heilbronn and Ulm (German) Railroad.—The idea is now abandoned of forming a grand railroad through Wurtemburgh from Heilbronn to Ulm. The difficulties presented by the nature of the ground are unusually great; it rises and sinks in alternate swells the whole length of the line, so as to offer facilities for nothing but an undulating railway. The Wurtemburgers are not, however, disposed to abandon the hope of participating in the advantages of the great discovery of recent times. A railway is now projected from Stuttgard to Carlsruhe, which is likely to be carried into execution. On this line, the difficulties, though not so great as in the other, are still by no means small, as along some extent of it there is the same wave-like conformation of country.

Railways in France.—A letter from Havre of the 9th says, "Our Chamber of Commerce met yesterday, to consider the question of iron railroads, to which so little attention has hitherto been paid. The members of the assembly appointed Mr. Reilly, President of the Chamber of Commerce, and Mr. Ferrere, to go to Paris, to take the necessary steps to obtain the line from Paris to Havre."—*Railway Times.*

Baltimore and Ohio Railroad.—The revenue of this railway has increased as follows:—

	Dollars.
Year ending 1st October, 1832	18,305,311
1833	19,167,835
1834	22,297,392
1835	26,336,862

Thus, in four years it had nearly doubled. The receipts during the month of August, 1836, exceeded those of August, 1835, by 142,260 dollars, and this, notwithstanding a great reduction of the tolls on the Chesapeake and Ohio Canal.

Railway Travelling.—Marshal Gerard was lately making a tour through Belgium, and while at Antwerp, walked to the gate of the citadel, expressing a wish to see it once more. He was told, that without an express permission from the government he could not be admitted. "But I am Marshal Gerard," said he, "I helped to take the citadel, and I think I might be allowed to enter it!" "If you were the king himself," replied the officer on duty, "you should not enter without the permission of the minister of war." An *employé*, hearing this conversation, went up to the Marshal and said, "If you will walk about the town for a couple of hours, I will undertake to procure a permission in the interim." The Marshal accepted the offer. The *employé* immediately started for Brussels by the railroad, and returned in less than two hours, with an order, not only to admit the Marshal, but to place five hundred men under arms to render him military honours. The distance from Antwerp to Brussels is upwards of 28 miles.—*Greenock Advertiser.*

TRANS-ATLANTIC RAILWAYS.

We find from the various recent arrivals from the West Indies and North and South America, that a spirit of enterprise in Railway speculations is very fast spreading over the New World.

Mexico.—It appears by the papers from Vera Cruz, that a contract has been entered into by General Bustamente, the President of the republic, with a gentleman named Senior Agostina, for the construction of a line of Railroad from the city of Mexico to the port of Vera Cruz. The distance is about 176 miles, and the country tolerably favourable, with the exception of one very abrupt rise of several thousand feet, which occurs at the commencement of the table-land, at a distance of about 15 miles from Vera Cruz. This once surmounted, it does not appear that any further important obstacle occurs upon the line; for the table-land of Mexico is one vast and fertile plain, and timber and other materials universally abound. The papers contain the most sanguine anticipations of the advantages to Mexico, which this work will produce; for though Mexico is one of the finest and most fertile countries in the world, yet agriculture and trade are in their infancy, and neither coffee, cotton, nor sugar are exported, because of the impossibility of conveying those articles to the coast, so destitute is the country of any thing deserving of the name of roads. How the rise at the commencement of the table-land is to be surmounted we do not as yet understand, but presume that a break in the line must be the consequence of so great an inequality, and that the traffic must be conducted up the mountain by mules, as at the present time.

Cuba.—At the date of the last arrivals, the attention of Governor Jacon was much occupied with experiments upon the Batabano Railway, with the steam locomotive engine which had arrived from England some time before. The Railway was not quite completed in the neighbourhood of Batabano, but the entire line would probably be opened, with the commencement of the business of the ensuing winter months. The port of Havannah was very sickly, and almost destitute of shipping, as usually is the

case at that season of the year. It may give some opinion of the value of this magnificent island, to remark that the imports of the past year were valued at 22,551,969 dollars; and the exports 15,398,248 dollars; whilst the number of ships entered at the various Custom-houses was 2,353; making an agregate of trade considerably greater than the island of Jamaica itself. Hence it is seen that the introduction of the Railway system is by no means premature in so wealthy an island. Railways and steam locomotive power are peculiarly adapted to hot climates like that of Cuba, where the abbreviation of human and animal labour is so much more to be desired than in colder and more populous countries.

Isthmus of Panama.—A contract was entered into in the course of the recent year, between the government of New Granada and a French gentleman, for the construction of a Railroad across the Isthmus of Panama; but it does not appear that a commencement had been made at the latest dates. There are only twenty-one miles of land between the port o Panama and the city of Chagres, which is upon the river of the same name, which falls into the opposite sea. But, though this comparatively small distance intervenes between the waters of the Pacific and Atlantic Oceans, it is unfortunately a most mountainous tract of country, and the difficulties of forming a Railroad very great, if carried in a direct line. The present contractor has, however considerable powers as to the choice of his line, and large privileges as to the land and materials required.

In *Brazil* we find that a number of short Railroads are proposed, for the purpose of overcoming the difficulties arising from the interruption of the navigation of the principal rivers by sand bars. At these positions it is proposed to form Railways upon the banks of the river, and for the present to construct them entirely of wood. A company had been formed for the purpose of running omnibuses in the city of Rio de Janeiro, and the vehicles were to be ordered from England forthwith.—*Railway Times.*

ENGINEERING WORKS.

Thames Tunnel.—We are glad to find that the public can again be admitted to view this stupendous undertaking, it appearing that the whole of the water and strata of sand, clay, and gravel, which had forced their way into the tunnel during the last eruption of the river, have been entirely cleared out. We are also happy to understand that along the comparatively short distance which the works have now to progress to low-water mark at Wapping, a more effective covering o. the bed of the river is about to be deposited, by permission of the Thames Navigation Committee.

A new lighthouse, which will cost £5,000, is about to be erected by the Trinity House, near that point in the Isle of Wight off which the unfortunate ship Clarendon was wrecked last year.

Safety Valves for Steam Boilers.—M. Sorel has announced to the Academy of Science, that his safety valves for the security against explosion in steam boilers are completed, and requested the appointment of Commissioners to examine them. The apparatus is fixed to a steam boiler in the manufactory of M. Bourdon, Engineer and Machinist, Fauxburg du Roule, Paris.

[The above notice furnishes no clue to ascertain the value of this safety apparatus; we shall be happy to publish any description of the valves, and also any account of experiments entered into by the Commissioners appointed by the Academy, with which the Inventor may favour us.—Ed.]

Embankments from the Sea.—There seems to be no operation connected with agriculture which promises more immediate and important results that the reclaiming of submerged lands in the estuaries in our large rivers. Till within these thirty years, the sole object contemplated in embanking submerged grounds, seems to have been the exclusion of water from the surface of soil which required only to be protected from its occasional invasions, and kept dry merely to make it eminently fit for most productive cultivation. Within the last twenty years, a system has been entered on, and is now, in the Forth and Tay in particular, being carried out to the most astonishing extent, not only of bringing into a cultivable state lands already, but for the periodical submergence, fit for cultivation, but of causing rivers to precipitate their mud in convenient localities, and so of creating fields where nothing before existed but a gravelly river bed, covered by from eight to twelve feet of water every tide, of the most unprecedented and unlooked for productiveness.

In the Forth, 350 acres of this sort of land have been, in the last twelve years, reclaimed by Lady Keith, at a cost of about £21,000, and affording an annual return of about £1,400, or nearly seven per cent. In the Tay, seventy acres have been recovered opposite to the shores of Pitfour, 150 on those of Errol, and twenty around Mugdrum Island, making in all 240 acres, at about an outlay of £7,200, yielding an annual rent of about £1,680, or upwards of twenty-three per cent. On the Errol estate alone, 400 acres are just about to be embanked, in addition to the above 150, all of which may probably be in cultivation before 1847. Off the shores of Seaside, a wall just now being built, 800 yards in length, will effect the recovery of not less than 150 acres; and on Murie property, 60 acres might be taken in by seed-time 1838. The operations of the embanker, which began off Pitfour in 1826, will thus probably have been brought into cultivation before 1816, on a shore of not more than seven miles in length, no less than 810 acres of land, renting at from £6 to £7 per acre, or of a gross annual value of £5,670, and a gross total value, at twenty-five years' purchase, of £141,750. This is a clear creation of £117,450 of new agricultural capital, taking the reclaiming cost at £30 an acre. The junction of Mugdrum Island to the north shore would probably afford 1000 acres at a single operation, while thrice that surface might be obtained betwixt Errol and Invergowrie.

The capabilities of the Forth, over and above what has already been effected above and below Kincardine, are not much, if at all, behind those of the Tay, though no sufficient inquiry has been made to permit details to be gone into.

The basin of Montrose affords a surface of nearly 3,000 acres, all capable of embankment, and which, by being relieved of the salt water of the ocean, which every tide at present overflows them and keeps them submerged for twelve hours out of every twenty-four, and irrigated by the fertilizing current of the Esk, which, for at least forty days every season, bears along with it not less that 1.800th part of its weight of the richest mud, might speedily be made not less productive than those of the Forth or Tay.

It is probable that between North Berwick and Montrose are to be found the most favourable localities for embanking on the east coast of Scotland, if not indeed the only ones which could be made available with a sure prospect of profit. It would be at the same time wo l that the débouches of all our great rivers were examined, lest at the mouths of the Spey, the Dee, the Don, the Esk, and the Tweed, might lurk localities equally accessible to the embanker, and equally unlooked-for, more than in the Tay or Forth thirty years since.

If the harbours on both sides of the Forth be examined, as low down as Dunbar on the one side, and Crail on the other; and those on the Tay down to Broughty Ferry; those on the Esk to Montrose and Ferryden, larger quantities of silt will be found accumulating in each of them, quite as impalpable and fine, and probably, if freed of salt, as fertile as those deposited and taken in higher up the rivers. It is probable, then, that lands might be embanked much farther out in these estuaries than seems at present to be suspected, by much the greater part of the agillaceous flocculi which the river bears along with it being actually carried out to sea.

The various embankments hitherto completed have been constructed by those manifestly little acquainted with hydraulic engineering, with little concert amongst the proprietors, and without almost any recognition of general principles or systematic plan of procedure. Many anomalies are consequently apparent in the now finished works, and many cases of useless expense and annoying inconvenience have arisen which it would have been most desirable and no difficult to have avoided.

On these and on many other grounds which must be apparent, but to enter into a detail of which would be much too tedious for the present memoranda, it seems most important that something should be done in the way of an historical account of all the embanking operations of any importance in Scotland, whether for the purpose of merely defending lands previously existing, but liable to periodical inundations, from tides or river freshes, or for the purpose of obtaining and enclosing accumulations of silt, which, but for the skill and industry of man, would have been wholly swept away.—*The Quarterly Journal of Agriculture, Scotland.*

NEW CHURCHES AND PUPLIC BUILDINGS.

Trowbridge Church, Wilts.—The notice of this edifice, in our last Number, was incorrect in some of the particulars. We have received the following corrected statement.—Plan, cruciform, with a tower over the *south* transept. Style, early English, about the latter end o' the thirteenth century. Material, stone. Interior, vaulted ceiling to the whole, with nave and side aisle groining. Accommodation, 1,026 persons, with but one small gallery at west end for 100 children. Dimensions, extreme length inside, from east to west, 109 feet, extreme width inside, from north to south walls of transepts, 96 feet. Cost, 4,760*l.*

Portsea.—A church capable of containing 1,200 persons, with galleries on north, south, and west sides, is about to be erected in this parish, from the designs, and under the superintendence of Augustus F. Livesay, Architect, Portsea. The church to be in the form of a cross, with nave, transepts, and a chancel. Style: early pointed English Dimensions, extreme length inside, from east to west, 88 feet, extreme breadth in transepts, from north to south, 63 feet. Cost, 2,900*l.*

Newtown, Hants.—The beautiful little church recently built at this place, as the last and noblest act of the late corporation, and under the superintendence of A. F Livesay, Esq., Architect, of Portsea, was consecrated on Nov 1, 1837, by the Bishop of Winchester. After the service was concluded, his lordship stopped to admire the beauty of the structure, which he was pleased to designate as 'Newtown Cathedral,' declaring, that in his extensive diocese it was second only to the church at Old Gatton. In this, we believe, his lordship was perfectly correct; for the uncommon beauty of the church, together with the surpassing splendour of the great east window, will make it a special object of attraction to the tourist."—*Hampshire paper.*

Leeds.—A cruciform church, in the perpendicular English style, 66 feet long and 27 feet wide, the chancel 22 feet by 20, and the transepts 18 by 20 feet each, with gallery at the west end, to contain 600 sittings, is just completed, at Headingley, in the borough of Leeds, Yorkshire, from the designs, and under the superintendence, of R. D. Chantrell, Esq., of Leeds, F.R.I.B.A. It has a tower at the west end, with octagon, belfry, and spire, together 97 feet high; total cost, 2,450*l.*, including hot-water apparatus. Professor Murray's lightning conductor is attached to the spire: this is constructed with ½ inch copper tubes, screwed to a cap, gilt point at the summit, and terminates at the base in a stone trough of water, supplied by the waste water-drain from the supply cistern for the warming apparatus. This church is built by subscription of the inhabitants of the village. it is built with a millstone grit, from Watwood, near the place.

Skipton.—A church, in the early decorated style, was begun last June in Skipton: length 72 feet, breadth 52 feet; octagon pillars and arches supporting a clerestory; the side aisles are each half the breadth of the nave; the chancel is 32 feet by 21, rises nearly to the height of the nave, and has side aisles to appearance externally, which form the entrances, vestry, and robing room; the seats (pews and free) are all formed alike, are 3 feet in width, and, allowing 20 inches for sitting, the body contains 540 sittings; the chancel or choir is raised by five steps, and the pulpit and reading-desk are on each side of the chancel arch; the tower is 16 feet square with a. The church is built upon a low site, and the greater part of the foundation is upon a bed of concrete, the east end being upon clay, and the west upon gravel and loose sand · the whole is vaulted with stone; the average depth of the vaults 12 feet, to suit the site, and elevate the ground floor to the level of the Canal Bridge adjacent. The cost will be 4,000*l.* R. D. Chantrell, Esq., F.R.I.B.A., Architect.

New Churches have been recently built at Milnthorpe, Westmoreland; Tintwistle, Chester; Bamberbridge, Lancaster; Colchester; Augworth, Lancaster. Southport, Lancaster, called Trinity Church. It is a neat composed brick building, in the early English style, with a tower; it is calculated to accommodate 500 persons. Goring, Sussex. The erection of this beautiful church, on the site of the old one, has cost, including its six bells, about £6,000, which has been solely defrayed by David Lyon, Esq., who has a seat near.

St. Dunstan's, Stepney.—Three large Gothic churches are now building in this extensive parish; one near Arbour-square, Commercial-road; one at Mile-end, and one at Ratcliffe.

Additional churches will be shortly built in the parish of St. George in the East.—*Gentleman's Magazine.*

New Church, Ratcliffe, in the parish of Stepney, is being erected under the direction of E. Lapidge, Esq., Architect; the form of plan is a parallelogram, 75 feet in length and 49 feet wide, with side and end galleries; the style is early English; it has a bell-

turret and spire, the base of the turret forms the entrance vestibule; the material brick with stone dressings; accommodation for 1,022 persons; contract under £4,000.

Liverpool.—A new Church is proposed to be erected by subscription at Waterloo, near this town; and three more in the immediate neighbourhood, on the Cheshire side of the Mersey. One is now in the course of building at Accrington, near Blackburn, in the early English style, with a tower and spire; to accommodate about 1,600 persons. It is to be built of the hard freestone of that district, and is estimated to cost £5,000. The architect is A. Y. Williams, Esq., Liverpool.

Hawley Green Church, Yately, Hants.—This Church was consecrated on Thursday, the 21st of December, 1837, by the Lord Bishop of Winchester. The church contains 306 sittings; nearly one half of which are free. The cost of the church alone is within £700 and the total expense, including fences, amounted to £970. The corner-stone of this church was laid on the 28th of July last, and the whole has been completed within the short space of five months. It is a very neat Gothic structure, with plain lancet windows, and bell turret at the west end. Robert Ebbels, Esq, of Trysull, Wolverhampton, Architect.

The Parish Church of Windlesham, Bagshot, Surrey, is about to be considerably enlarged, under the directions of Robert Ebbels, Esq., of Trysull, Wolverhampton, Architect.

Wincanton, Somersetshire.—A National School is now erecting from the designs, and under the superintendence, of R. G. Clark, Esq., Architect, of Bognor, Sussex. The building is of stone, and in the Gothic style, the first stone was laid by the Bishop of Bath and Wells last July, before a large concourse of people. It is to contain 240 children, the cost is £500. C. N.

FOREIGN INTELLIGENCE.

GERMANY.

The Cathedral at Halberstadt, which is justly esteemed one of the most admirable monuments of Gothic architecture in the north of Germany, has been fully described and illustrated in a folio volume, with seven plates, by Dr. Lucana, of Berlin. Of this church, the older part was begun in 814; but the first structure having been nearly destroyed by Henry, surnamed the Lion, in 1179, the present edifice, or addition to what remained of the former one, was commenced in 1181, and consecrated in 1220. The works, however, continued to be carried on long after the last mentioned date; the choir, for instance, not being finished until the following century. As shown in two views, plates 3 and 5, the interior of the church is highly imposing, and the painted windows of the choir and Bishop's chapel produce a rich and harmonious effect. The grandeur of the edifice generally is fully equalled by the variety and elegance of the ornamental details, which are so numerous, that they alone would furnish a series of architectural studies of considerable extent. The Bishop's stall is esteemed one of the greatest ornaments in the church, and is, in fact, a most exquisite piece of design, in which fertility of invention, ingenuity, and taste, are complete with each other.

Bavaria.—On the 6th of December, a meeting was held of the two Committees of the Augsburg and Munich Railway, one from Augsburg and the other from Munich, at which all differences were adjusted. We may, therefore, hope that all the obstacles which have hitherto opposed the execution of this line, one of the most promising and interesting in Germany, will now be removed. The delay which has occurred in the progress of this useful undertaking, in a country which has of late years become famous throughout Europe for its advances in public improvement, has occasioned not a little surprise, and, it has been hinted, would never have taken place had the Government shown half as much interest in the furtherance of a railway as of a picture-gallery or a "Valhalla."

Pesth.—Of two new edifices in this city, one is now completed, the other now in progress. The former is the National Hungarian Theatre, which was opened in August last: it was erected chiefly by voluntary contributions, and is said to be fitted up in an exceedingly tasteful style. The other is for the National Museum, and will, when completed, be the largest building in the whole city.

Hamburg.—Some time ago there was a competition for the new Exchange, to which foreign architects were invited, by public advertisement, to send in designs. The committee have now adjudged the first premium (100 louis d'ors) to Zwirner, of Cologne; and the second (100 ducats) to Maack, of Hamburg. Whether any designs were sent from this country, we have not heard.

Italy.—We are happy to learn that surveys are now making of the line of railway from Venice to Milan. The engineers who are employed are under the direction of Signor Milani.

LAW PROCEEDINGS

Bristol and Exeter Railway.—On Monday last, the 27th of November, an Inquisition was held at Weston super-Mare, before the Under-Sheriff, Edward Coles, Esq., and a highly respectable Jury, to assess the value of land required by the Bristol and Exeter Railway Company from C. H. Payne, Esq., at Uphill.

The damages were thus assessed by the Jury:—

The value of the land	£98 10 0	
Compensation for severance	58 0 0	
		£156 10 0

After delivering the verdict, the Foreman added, "That the Jury desired to express their unanimous opinion, that the conduct of the Company throughout the transaction had been highly honourable and liberal, and entitled the Directors to the entire confidence of the landowners, that they would be fairly and equitably dealt with in their negotiations and arrangements with the Company."—It was given in evidence that the Company had offered Mr. Payne 200*l*., in order to avoid the expense of proceedings before a jury. By the 30th section of the Act of Incorporation it is provided, that in case of a verdict for a less amount than had been previously offered by the Company, a moiety of all the costs, charges, and expenses of summoning the jury, and of witnesses, is to be borne by the owner of the land, and may be deducted from the sum awarded.—*Bristol Gazette.*

MISCELLANEA.

British Museum.—Within the last month, two new rooms have been opened to the public, in the gallery on the west side of the building, over the gallery of antiquities, the approach to which is from a spacious stone staircase at the extremity of the latter. One of these is devoted to Etruscan antiquities, several of which have been removed from the room known as Sir William Hamilton's collection; and the other expressly to the monuments and records of ancient Egypt. Of these there are several mummies and mummy-cases, the names of the owners of which have, as far as could be deciphered from the hieroglyphics, been attached to them: some of the latter are very rare and curious. The collection has lately received many rare additions of the household furniture and implements of this interesting nation; and amongst the most singular relics must not be omitted those votive offerings which were placed within their vaults to nurture the spirit on its passage to the other world. One of these relics, along with a basket of fruit and different varieties of bread, consists of three baked fowls, which are as firm and attenuated as the bodies of those for whose nutriment they were furnished.

Hydraulic Telegraph.—A novel and ingenious method of conveying intelligence from one place to another has lately been invented by Mr. Francis Whishaw, of South-square, Gray's Inn. The principle on which the process is carried on depends on the well known fact of water always finding its level. The invention is worked by the rising or depression of water, and is therefore appropriately called the "Hydraulic Telegraph." In the experiments which have been made, sentences of several words have been communicated with the greatest rapidity from one room to the other, and the interpretation, although the vocabulary of Mr. Whishaw at present has not above 12,000 words, has been perfect. The rough estimate of the expense of a telegraph of this sort, including stations and contingent expenses, is 200*l*. a mile. The invention is exceedingly curious, though dependent on a well known and simple principle.

Means of Conveyance in the United States.—Notwithstanding the late commercial calamities with which we have been visited, and notwithstanding that the tolls on the Erie Canal, the great channel by which commerce flows from the mercantile emporium of this country towards the far west and the lakes, have decreased, it is gratifying to learn, by the late statistical returns of the canals and railroads of Pennsylvania, from Philadelphia to the west, that instead of a decrease, there has been a considerable increase in the amount received during the past year, as compared with the previous one. The amount of canal and railroad tolls received in Pennsylvania, for the fiscal year, ending on October 15th last, was 892,384 dollars, being 54,578 more than the preceding year. I dwell upon this fact emphatically, because these railroads and canals are the grand highways between the Atlantic cities and the western states and rivers. It is true, had not the pressure, to which I have so frequently alluded, taken place, a great increase would have been apparent in the tolls above referred to, and hence in the general business of the country. As it is, the increase has been by no means inconsiderable; and it proves that no circumstances, no temporary panic, can repress the energies of this mighty people. While upon this subject, and with a view of showing the enterprise and liberality of individual states, I may mention the fact, that the great line of canals and railroads connecting Philadelphia with Pittsburgh, and thus the waters of the Delaware and the Ohio, has cost Pennsylvania upwards of 20,000 dollars! The consequence is, that the people of the commonwealth of Pennsylvania have been very heavily taxed, and yet they are as decided and unequivocal in their attachment to all judicious and proper improvements as ever. Even now they are making arrangements for a great railroad to connect Philadelphia with the lakes, and thus to afford a new channel for the united wealth of the "Great West."—*Philadelphia Correspondent of the Morning Chronicle.*

Grand Junction Railway.—Early on Friday morning last, one of the bridges under the railway near Warrington gave way, owing to a very heavy fall of rain, which had inundated a large tract of country between Warrington and Manchester, and which, in flowing through the bridge, washed away the earth between the piers, and thus undermined the foundation. A temporary bridge of wood was soon erected, across which, during the whole of Friday, passengers with their luggage had to pass. In this way a delay of about half an hour was involved. The directors met in the course of the day, and issued a notice that until another bridge was constructed, passengers would be liable to the inconvenience of changing luggage; but before this notice was published, by the activity of the company's agents, a wooden bridge for carrying the railway was constructed, across which all the trains on Saturday passed, and business has since proceeded as before. Mr Locke, the company's engineer, who was in London attending a trial at Guildhall, was sent for by express, and reached Warrington early on Sunday. He expressed himself quite satisfied with the measures that had been taken, and is now proceeding to rebuild those parts of the bridge that had been carried away.

Liverpool, Dec. 25, 1837.

TO CORRESPONDENTS, AND NOTICES.

We consider the Spring Wheels of Mr. Mackenzie's wholly inadmissible in practice, their complexity, the expense of construction, and liability to derangement is such, that we could not recommend their adoption in any case. The Drawings, which are very beautifully done, are at our Publisher's Office, and may be had on application.

"An Architectural Student", is informed, that the qualification of Competitors for Prizes proposed by the Architectural Society, is, that they must be Members of the Society.

We cannot answer Mr. Prosser's inquiry with confidence, as to the correctness of the description in Moore's Improved Almanack for 1838, relative to "Compressed Bricks being cheaper than ordinary bricks, and harder than granite." (!!) We very much doubt both statements. We had intended to have continued a series of experiments on the strength of bricks, which we commenced some time since, but our professional engagements have prevented us; as soon as we can spare time we will proceed with them, and then put to the test whether "compressed bricks are harder than granite." In the mean time we shall be obliged for any communication on the subject.

We regret that we have not space for Mr. Davy's communication in our present number; also those of J. J., an Old Engineer, and other Correspondents.

Books for Review should be sent early in the Month—Communications on or before the 20th—and Advertisements on or before the 25th Instant.

DRAINING BY STEAM-POWER.

Fig. 1.

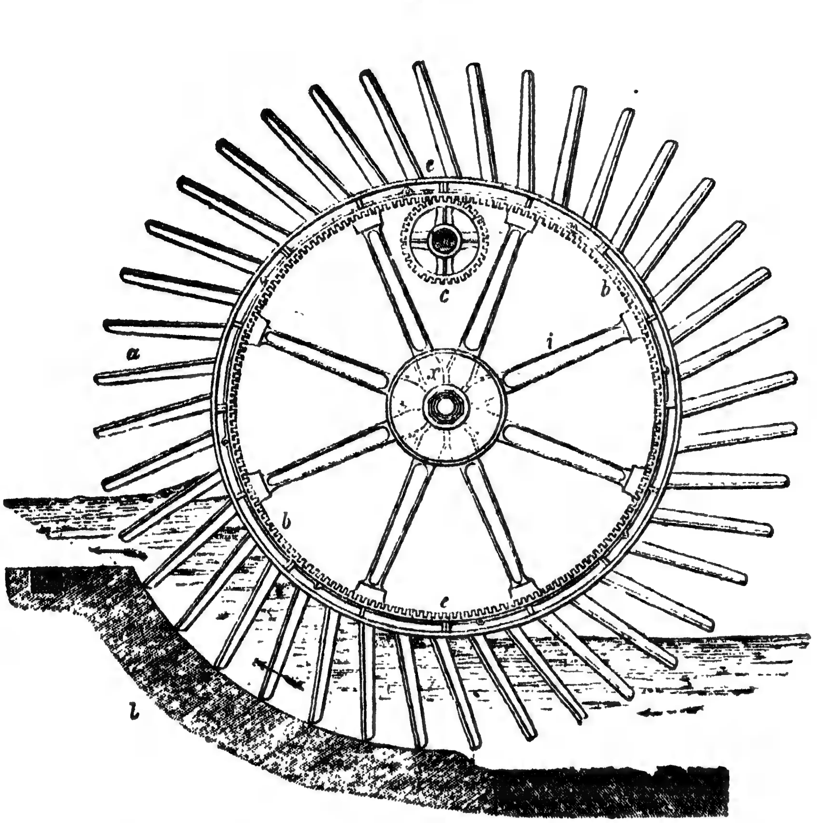


Fig. 2.

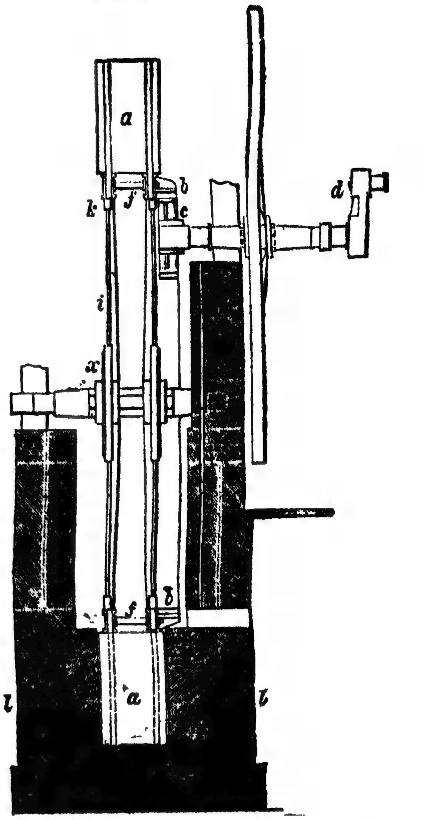


TRANSACTIONS OF THE SOCIETY, INSTITUTED AT LONDON, FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.

Vol. LI. London, 1837.

This Society, which may be considered the parent of most of our Scientific Institutions, has been established upwards of eighty years, and has distributed, in premiums and prizes for the encouragement of the arts and improvements in manufactures, &c., several thousand pounds in money and medals; through its medium has been brought to light many valuable inventions which otherwise would have been lost to the world; many men, now standing high in their professions, recollect well that feeling of enthusiasm which has supported them through all the difficulties of their progress towards distinction, was excited and kindled, in the first instance, by the rewards and commendations of this society; the valuable collection of models in the museum, and the many excellent papers annually published in the Transactions of the Society, fully attest its value to the public.

The disbursements of the Society are maintained, for the most part, by the trifling subscription of two guineas annually by members; but we conceive that a society so valuable and so national ought to receive the support of every friend to the improvement of the arts and education generally, and this is the more to be desired, as its finances are not now in so flourishing a condition as formerly; so that unless public patronage be extended towards the institution, its means of doing good will be materially curtailed.

The subscriber is entitled at all times to free admission to the museum and extensive library—the meetings, conversaziones, and various committees, each one affording a field for instruction and improvement.

We insert an essay on Draining, by Joseph Glynn, Esq., published in the last volume of the Transactions, as one proof amongst many of the highly useful and well-written papers abounding in them—a paper which may be read and studied by every man, professional or otherwise, with exceeding advantage.

"The Gold Isis Medal was voted to Joseph Glynn, Esq., Civil Engineer, for the following communication on his application of Steam Power to Draining Fens:—

Butterley, by Derby, Feb. 8, 1836.

"Sir,—I have thought it my duty to submit to the Society some account of a very important application of the steam-engine, which at present appears to be but little known beyond the immediate localities where it has taken place, and which has been successfully made in several extensive works wherein I have been engaged, for the drainage and improvement of fens and marsh lands, chiefly in Lincolnshire and Cambridgeshire, and which I believe would be found of great advantage in many other parts of England.

"As the introduction of the steam-engine, on the large scale, cannot, I presume, be uninteresting to the Society, which alike patronises agriculture and the arts, I trust I shall be excused in venturing to lay before you the following observations, illustrated by plans of three of the principal works of this kind, which have been executed under my superintendence.

"Although much has been done in the fen countries to improve the outfalls of their rivers, and to promote as much as possible the action of natural drainage, yet many districts are so situated, that, without the aid of mechanical power, they must still have remained little better than waste swamps, affording only a precarious summer pasturage for cattle.

"The introduction of the wind-engines, or Dutch mills, was therefore of great utility, as their use enabled the fen farmers to throw off a large portion of the water, and, by raising the banks round their districts, they kept them so far dry, that in favourable seasons they reaped abundant harvests, the great fertility of the soil returning them large crops of wheat when brought into tillage.

"But here the farmer was subject to great risks. Often, when his crops were almost ready for the sickle, he had the mortification to see the rain fall in torrents when there was not a breath of wind to turn his mills, which stood motionless with their sails spread to catch the vainly expected breeze, whilst the produce of his fields perished on the ground.

"The aid of the steam-engine is, therefore, invaluable in the fens; and the extent and fertility of these lands, when properly drained and cultivated, render them an object of almost national importance. The fen districts in the Bedford level alone amount to nearly 300,000 acres, and the whole of the fen and marsh lands in England is, perhaps, not less than 800,000 acres.

"In one of the districts where I was employed, I found the rich black earth formed of decomposed vegetable matter, to be upwards of thirty feet in depth.

"Few persons, I believe, are aware how small a quantity of mechanical power is sufficient to drain a large tract of fen land. Generally speaking, there are no natural springs; and when the upland waters are banked out and carried into the rivers by catch-water drains, we have to lift that water alone which falls from the clouds. The quantity of rain which descends on the flat eastern counties of England, is less than in any other part of the island, seldom exceeding 26 inches in depth in the year, whilst in the hilly western counties of Lancaster and Westmoreland it often amounts to 54 inches in depth. It would seem almost like an arrangement made by Providence to place the cultivation of these rich lands within the compass of our ability.

"In many months the evaporation is greater than the downfall, and it then becomes necessary to open the sluices, and let in water from the rivers to moisten the earth and to supply the cattle, which, when steam-engines are used, may be done without fear.

"If the wind-engines could be depended upon, they might be rendered sufficient for the purposes of artificial drainage; but it unfortunately happens, that when there is most rain there is generally least wind, and the mills are useless when all depends on them. The steam-engine ensures certainty; it is ready to act whenever it may be wanted; and the first cost and subsequent maintenance of one powerful steam-engine is less than the expense of building, repair, and attendance on a great number of windmills. In one large district where I was employed, named Deeping Fen, near Spalding, and now drained most effectually by two steam-engines, there were forty-four windmills for lifting the water.

"I would here remark, that I do not claim the merit of having originated the idea of employing the steam-engine in the drainage of land. It did not escape the great mind of Smeaton, who gave it as his opinion, that it would one day become a powerful agent in the improvement of the fens; and subsequently his pupil and successor, the late Mr. William Jessop, I believe, on one occasion, unsuccessfully recommended its adoption. Afterwards, the late Mr. John Rennie endeavoured to introduce steam-engines into the fens, but he could only prevail on the proprietors of one district to erect a small steam-engine in aid of their windmills, consequently it had not a fair trial; and here the matter rested for many years.

"I am happy, however, in that I have been able to realize what these great men had imagined; and in so doing, I have not only caused "two blades of grass to grow where but one grew before," but I have had the pleasure to see abundant crops of wheat take the place of the sedge and the bulrush. I have been fortunate, in that I have been permitted to carry these improvements to a greater extent than I could possibly have anticipated; and, whilst I confess myself ambitious of obtaining some mark of the Society's approbation, I trust that, through the means of their widely-circulated Transactions, the knowledge of these things may be further extended, not only in England but on the Continent; and that when it is known by what comparatively small means the swamp or marsh, exhaling malaria, disease, and death, may be converted into fruitful corn-fields and verdant pastures, the blessings of health and abundance may be still more widely spread. I beg to apologize to the Society for this digression, which has led me away from the practical part of my subject.

"In most cases it is not requisite to raise the water more than three or four feet higher than the surface of the land intended to be drained; and even this is only necessary when the rivers into which it is delivered are full between their banks, from a continuance of wet weather, or from upland floods.

"In some instances, the height of water in these rivers is affected by the tides, so that drainage by natural outfall can only take place during the ebb; in others, the rivers, uninfluenced by the tides, form the means of drainage, but have not fall or descent sufficient during heavy rains to carry off the water.

"In all these cases I have erected steam-engines for draining marsh land with complete success, and the plans* which accompany this paper will explain their application.

"I have stated, that the quantity of rain fallen in the fens on the eastern side of the island seldom exceeds 26 inches in the year; and that it is with the rain alone we have to contend, the upland waters being banked out, and there being no springs in the fen. If there be rising ground within the district, or uplands adjoining, whose waters cannot be banked out, the surface of such lands must be taken account of in our calculations as if they formed a part of the district.

"If we suppose that in any one month there fall 3 inches depth of rain, of which 1 inch is absorbed and evaporated, we have $1\frac{1}{2}$ cubic feet to every square yard of land; and this multiplied by 4840 (the number of square yards in an acre), gives 7260 cubic feet of water to the acre.

"I have found it expedient in practice, to keep the water in the drains within the district about 18 inches below the surface of the cultivated land; and if we must raise it $3\frac{1}{2}$ feet higher than the surface, which happens very generally to be the case, especially when the water is high in the rivers, our lift between the surface of water in the drains and that of the outfall river will be 5 feet. I have generally caused the principal or main drains to be cut $7\frac{1}{2}$ feet deep, and of width to give them sufficient capacity to contain the rain-water as it falls, and to bring it down to the engine, keeping it in full work within a descent or declivity of from $1\frac{1}{2}$ to 3 inches in a mile.

"I have always used scoop-wheels, the float-boards of which dip 5 feet below the water's surface where powerful engines are used, or $6\frac{1}{2}$ feet below the land in the level of the fen.

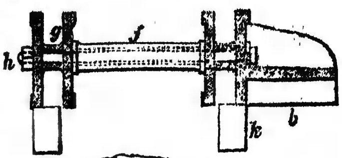
"The main-drains, then, are 1 foot deeper than the wheel-track, which allows for the deposition of mud and weeds, and facilitates the flow of water to the wheel. Such a wheel, in technical language, will be said to have 10 feet head and dip.

"These scoop-wheels I have made of cast-iron, with wooden float-boards, like the undershot wheel of a water-mill; but, instead of being turned by the impulse of the water, they are used to lift it, and are kept in motion by steam power.

"The details of the construction of these wheels are shown in the engraving.

* These plans, which consist of a very elaborate and excellent set of drawings, are deposited in the Society's collection, and are open to examination by those who are interested in such works.

Fig. 3.



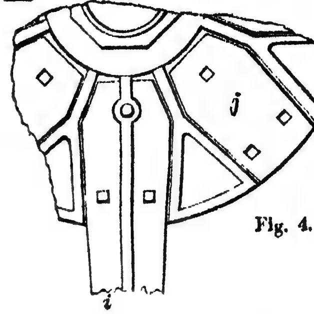


Fig. 4.

Fig. 5.

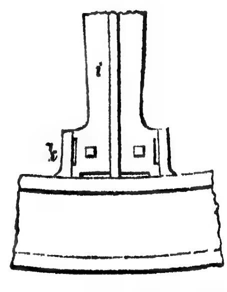

Fig. 6.

"Fig. 1 is a side view of the scoop-wheel.

"Fig. 2 is a front sectional view of the same, showing only the top and bottom paddle-boards and pairs of arms, and one top and one bottom tooth.

"*a a* the paddle-boards, each fastened to its pair of arms; *b b* the ring of internal teeth, which are engaged by the toothed wheel *c*, having on its axis a fly-wheel and a crank *d*, by the latter of which it is connected with the prime mover.

"The wheel is composed of 2 pair of rings, an outer and an inner in each pair, one of the latter of which is the ring of teeth *b b*, already mentioned. Each ring is cast in eight segments, which are joined as shown at *e e*, fig. 1. These four rings are kept in their proper places by several sets of hollow pillars, each set consisting of one long and two short ones, as *f* and *g g*, fig. 3; one long screw-bolt *h* passes through the three pillars, and also through corresponding holes in the four rings, and thus binds the whole firmly together. Each pair of rings is connected with the common axis by a set of arms or spokes *i i*, &c., the converging ends of which are secured in a circular flanch *x x*, fixed on the axis.

"The form of the recesses in the flanch into which the ends of the arms are fitted is shown in fig. 4, where *j j* are two such recesses, and *i* is an arm in its place, and made fast by three bolts. Fig. 5 is a cross section of an arm. Fig. 6 shows the outer end of one arm, and part of a ring: it is fitted into a recess or box *k*, which projects from the rim, and is secured by two bolts. These latter are cast with the two outer rings, as shown in the transverse section, fig. 3, *b*; in the same figure, is one tooth of the ring of teeth, fig. 1. The close fitting of the masonry that forms the channel for the water in which the paddle-boards *a* work, is shown in cross section *l l*, fig.2, and at *l*, fig. 1, in longitudinal section.

"The float-boards move in a track or trough of hewn stone or masonry, worked to fit them, as shown in the figure, the lower end of this wheel track being open to the main drain, the upper end communicating with the river, which is kept out when the wheel ceases working by pointing doors, like the lock gates of a canal. The float boards do not radiate from the centre of the wheel, but form an angle of forty-five degrees with the horizon at the point where they deliver the water.

"The diameter of the scoop-wheel should be such, that the surface of the water in the outfall drain or river may never rise higher than within four or five feet of its axis, otherwise the water might pass over the float-boards, and flow back again into the fen.

"I have found about six feet in a second to be the best speed for the circumference of the wheel, as that velocity gives sufficient centrifugal force to hold the water up against the "breast" of the wheel-track or trough of masonry, and yet not so much as to cause its being carried up by the float-boards past the point of delivery.

"As engineers, by common consent, make a horse's power to be equal to 33,000 lbs. raised one foot high in a minute, or 3,300 lbs. ten feet high in the same time, consequently, as a cubic foot of water weighs $62\frac{1}{2}$ pounds, and a gallon of water 10 pounds, a horse's power will raise and discharge from the fen, at ten feet high, 330 gallons, or $52\frac{8}{10}$ cubic feet of water in a minute.

"Now a good steam engine applied to work a scoop-wheel will consume about 10 lbs. of Newcastle coals in the hour for each horse's power, and in that time lifts and discharges 3,168 cubic feet, or 19,800 gallons of water (at a height of 10 feet) per horse's power per hour.

"I have taken the quantity of rain which may fall in excess on an acre of fen-land in a month to be 7,260 cubic feet, which one horse's power will raise and discharge in ($2\frac{29}{100}$ hours) about 2 hours and 20 minutes.

"Suppose, therefore, we wish to drain 1,000 acres of fen or marsh land, and that the upland waters are all banked out; we have an excess of rain equal to 7,260,000 cubic feet of water to raise and get rid of.

"A good steam-engine of 10 horses' power will do this in 232 hours, or less than 20 days, working 12 hours per day, and I have found these calculations fully supported in practice. It is true, that the rain due to any given month may fall in a few days, but in that case the ground absorbs a good deal of it, and I have before observed that the drains must have capacity enough to receive and contain the rain as it falls; besides, in case of need, the steam-engine may be made to work 20 hours per day instead of 12. It is also true that, as the dip of the wheel lessens, the quantity of water discharged is

[illegible] safe, for the upper edges of the float-boards are 18 inches below the level of the land.

"In order to show what has been done in actual practice, I here beg leave to submit the results of an experiment made with one of the engines of 80 horses' power, which I have erected at Pode Hole, in Deeping Fen, near Spalding, Lincolnshire. The quantity of water thrown being ascertained by the contents of a portion of the main drain, partitioned off for the purpose by dams, properly planked and secured by puddling of clay.

Results of an Experiment made with the Eighty-Horse Engine at Pode Hole, on the 18th of July, 1830.

Time the Engine was at work.	Coal burnt.	Mean Lift at which the Engine worked.	Mean Dip of the Wheel.	Weight of Water raised per Hour.
	Bushels.	Ft. In.	Ft. In.	Tons.
1st hour's trial . . .	$12\frac{1}{2}$	6 $7\frac{1}{2}$	3 4	9,810
2d ditto ditto . . .	12	6 10	2 10	8,520
3d ditto ditto . . .	$11\frac{1}{2}$	7 2	2 6	7,560
4th ditto ditto . . .	11	7 5	2 2	6,660
5th ditto ditto . . .	10	7 6	1 10	5,700
6th ditto ditto . . .	10	7 6	1 6	4,740
7th ditto ditto . . .	10	7 6	1 3	4,220
8th ditto ditto . . .	10	7 6	1 2	3,990
	87			51,230

"The water-wheel is 28 feet in diameter, its float-boards are $5\frac{1}{2}$ feet in depth by 5 feet wide, and they travel with a mean velocity of 6 feet in a second. The section of the stream delivered, when the engine has its full dip, is, therefore, $27\frac{1}{2}$ square feet, and the quantity discharged is 165 cubic feet, equal to more than $4\frac{1}{2}$ tons of water in one second, or about 16,200 tons in one hour.

"It will be observed, that the float boards had only 3 feet 4 inches dip, instead of 5 feet 6 inches dip, at the commencement of the experiment, or, in proportion to the full dip, as 20 to 33, or as 9,810 tons, the quantity lifted in the first hour, are to 16,230 tons; so that the trial proves the correctness of the calculation.

"It will also be remarked, that had the wheel been working with a full dip, "the head," that is, the lift from surface to surface of the water, would have been only 4 feet 6 inches, instead of 6 feet $7\frac{1}{2}$ inches. At the end of the eighth hour the enclosed portion of the main drain, which was $6\frac{1}{2}$ miles in length, and averaged at the water's surface $34\frac{1}{2}$ feet in width, being so far emptied of its contents that the float-boards of the scoop wheel dipped only 14 inches in the water, it was useless to continue working the engine.

"The fuel used during this trial, was Yorkshire coal, of which the average consumption was about $10\frac{1}{2}$ lbs. per horse power per hour. From 8 to 9 lbs. of Newcastle coal would, with this engine, be found to do the same quantity of work.

"I have drained two districts of fen land, near March, in Cambridgeshire, where the engine's power bears about this proportion of 10 horses' power to 1,000 acres of land, and the water can always be kept down to any given distance below the roots of the plants. If the rain fall in excess, the water is thrown off by the engine; if dry weather prevail, they can open the sluices without risk, and let the water flow in from the river, to fill the drains and moisten the earth.

"The engines work about four months out of the twelve, at intervals varying of course with the season. Where the districts are tolerably large, and the drainage effected by steam power, the annual expenses, including all charges, will not exceed 2*s.* 6*d.* an acre. The first cost of the works varies, of course, in almost every district, from the nature of the substrata; but generally I have found that it amounted to about 20*s.* an acre for the requisite machinery and buildings: that is to say, an engine of 40 horses' power, with its scoop-wheel, machinery, and buildings erected for the drainage of 4,000 acres of land, cost about 4,000*l.* I have found this to be the case in four different districts.

"Where the clay or other firm measures lie near the surface, so that we can either dig down to them, or drive short piles, I prefer the steam-engines in the form generally used in cotton-mills and other manufactories, and commonly called by workmen, "factory-engines;" but where it is necessary to drive long piles, and to plank and cross-plank over them, so as to form an artificial foundation or platform to build upon, I prefer the "marine engines," that is to say, in the form usually adopted on board of steam-packets, which is more compact, requiring smaller and less expensive foundations.

"The districts wherein I have been employed are eleven in number; the quantity of land drained or improved is about 90,000 acres, and the steam power used is equal to 620 horses.

"In many places, persons who were able to foresee the consequence of these improvements, and to avail themselves of it, have purchased land at from 10*l.* to 20*l.* an acre, which they may now sell at from 50*l.* to 70*l.* an acre, producing from four to six quarters of wheat to the acre.

"Many of these gentlemen farm their own land; are commissioners by qualification; they live in abundance on the produce of their fruitful soil, and their hospitality and kind attention I have every reason gratefully to acknowledge.

"I will now mention these districts in the order their works were undertaken, with the quantity of land and the power used in each case, and attempt an explanation of the drawings sent herewith.

[illegible]

"Deeping Fen, near Spalding, Lincolnshire, in 1825, containing about 25,000 acres, is effectually drained by two steam-engines of 60 and 80 horses' power, the larger one being made entirely under my superintendence at the Butterly Iron Works; the 60-horse engine by Fenton and Murray. The scoop-wheels and machinery for both engines were entirely made and put together at Butterley, under my direction. The cast-iron toothed wheels used were of necessity very strong, more so, indeed, than any I had seen, being 15 inches in width across the face of the wheel, and the pitch of the teeth, 5 inches.

"March West Fen, adjoining the town of March, Cambridgeshire; in 1826, about 3,600 acres are completely drained by an engine of 40 horses' power, and it is in contemplation to add about 400 or 500 acres to the district to be drained by the same engine.

"Misterton Soss, with Everton and Gringley Cars, in 1829; comprising an extensive district between Bawtry and the river Trent, of about 6,000 acres, more than two-thirds of which are marsh land, is effectually drained by a 40-horse power engine.

"The engine is situate about three-quarters of a mile from the Trent, and the outfall drain from the engine to that river is contrived, during the rising tide, or when the Trent is flooded, to form a capacious reservoir, into which the engine throws the water until it acquires sufficient head to open the pointing doors at the Trent side, and discharge its contents into the river. This is done when the Trent is flooded; but in favourable seasons, the sluices by the side of the engine are raised, and the district is drained by natural outfall; these sluices are also used in dry seasons to retain the water in the district.

"1830, Littleport Fen, near Ely, about 28,000 acres, drained by two steam-engines of 30 and 80 horses' power, but with a few of the old wind-engines still retained. Before steam power was used, there were seventy five wind-engines in this district; and often has the Fen farmer, in despair, watched their motionless arms, and earnestly hoped a breeze might spring up to catch their sails, whilst his fair fields gradually disappeared below the rising waters, and the district assumed the appearance of an immense lake.

"The large engine was entirely constructed under my inspection, and built from my drawings, at the Butterley Works; the small one was purchased by the commissioners, and I afterwards repaired and adapted it, so as to make it available for their purpose.

"As it was desirable that the large engine should be erected on the bank of the Hundred Foot, or New Bedford River, in which the tide rises to a considerable height, a scoop wheel, of large size and great strength, was necessary, the head and dip being at times not less than 16 feet; but when the tide was out, the head was much diminished, and I therefore made two speeds, or combinations of wheel work; so that the scoop wheel might revolve with greater velocity, and throw a larger quantity of water during the ebb, whilst the engine's full power and uniform speed were maintained at all times.

"The foundation was naturally very bad, there being seven yards in depth of black peat above the clay.

"To resist and to work against so great a head of water, I was compelled to take artificial means to make it secure, and, accordingly, I caused upwards of 600 strong piles to be driven firmly down into the clay. Having spiked to the pile-heads, which were sawn off to a uniform level, stout cross sills of Memel timber, the whole was planked over with 3-inch deals laid close together, and spiked down to form a complete floor under the whole of the buildings, so that if any settlement took place they might sink equally. The works, however, have stood as firm as a rock.

"The scoop-wheel is 35 feet in diameter, and with its axis and the toothed wheel-work upon it, weighs 51 tons, to which, when in action, the weight of water upon it must be added.

"The pinion on the engine-axis is 4 feet in diameter; it makes 13 revolutions per minute, and weighs 33 cwt.

"When the tide is high, this pinion works into a wheel of 24 feet in diameter, having internal teeth; the float boards on the periphery of the scoop-wheel then travel with a velocity of 212 feet per minute, and in that time discharge 3,519 cubic feet, or 21,980 gallons of water. When the tide is low, the pinion, by the help of machinery, is made to slide into action with another wheel of 16 feet diameter, having external teeth, and the float-boards then move at the rate of 318 feet per minute, delivering 5,278 cubic feet, or 32,880 gallons of water in the same time.

"Before these works were completed, many persons who professed to understand such matters predicted their total failure, and greatly alarmed the commissioners for the result; but their success in saving the district from being drowned, during a long continuance of heavy rain, which, without their aid, must have laid the whole of it under water, gave unquestionable evidence of their efficacy. The commissioners were pleased to make a public expression of their thanks for my services, conveyed in terms most flattering; and, by printing their resolutions in the local papers, to induce other districts to follow their example.

"Middle Fen, near Soham, Cambridgeshire, about five miles from Ely, in 1832. About 7,000 acres are drained by a steam-engine of 60 horses' power. The foundation was similar to that in the preceding district of Littleport, and the expense and difficulty encountered in that instance led me to adopt the marine engine here: the drawings Nos. 5, 6, and 7, show the arrangement. My success in Littleport Fen led to this understanding, several of the commissioners having estates in both districts, as also in the following.

"Waterbeach Level, lying between Ely and Cambridge, containing about 5,600 acres, was drained in the same year by a 60-horse power engine. The foundation here is a natural bed of concrete gravel, held together by an ochreous cement; a large patch of this was found at the very point where it was desirable to establish the works at an accessible depth from the surface, so that we could build upon it.

"Magdalen Fen, near Lynn, Norfolk, in 1834, contains upwards of 4000 acres, and is completely drained by a 40-horse engine, under circumstances similar to the preceding; the water is discharged into the Eau Brink Cut.

"March First district, or Binnimoor Fen, in Cambridgeshire, 1834. 2,700 acres of land are kept in the finest possible state of drainage by a 30-horse power steam engine; the water of about 300 acres of adjoining high ground drains into the fen. This is, perhaps, the most complete work of the kind in Cambridgeshire. It lies close by the town of March, and the commissioners were, therefore, desirous that the drainage should be perfect: as they instructed me to spare no pains to make it so, I trust their wish has been accomplished.

"Feltwell Fen, near Brandon, Suffolk, about 2,400 acres, drained or improved by a 20 horse engine, now just completed.

"Soham Mere, Cambridgeshire, formerly, as its name implies, a lake, of 1,600 acres in extent, and about 300 or 400 acres of higher land, the waters of which cannot altogether be excluded. As the lift is great, it is requisite to employ a 40 horse engine. These works are now constructing; they are in a forward state, and will soon be in operation, I trust with success.

"I have exceeded the limits I at first proposed to myself, and, I fear, trespassed on your time; I therefore refer to the plans, which I hope will further elucidate the subject, and respectfully submit them to the Society.—I am, sir, &c. &c. JOSEPH GLYNN.

"A. AIKIN, Esq., Secretary, &c. &c.

"Whilst I was writing the preceding paper, I thought it expedient to apply to Mr. John Tricket, superintendent of the works at Deeping Fen, for an account of the quantity of rain which had fallen in his district during the last two years, and what quantity of water he had thrown off with the steam engines, to which I received the following reply:—

"Sir, *Pode Hole Engines, Feb. 11, 1836.*

"According to your request, I have sent you a copy of my log book for the last six years, knowing it would be better information for you than if I had given you the last two years only, as it gives some wet seasons. We are working day and night at this time, and, I am happy to say, are giving general satisfaction. The district we drain is about 25,000 acres. I am, sir, &c.

"JOSEPH GLYNN, Esq., Butterley, near Derby. "JOHN TRICKET."

REVIEWS.

Eastbury, illustrated by Elevations, Plans, Sections, Views, &c. By THOMAS HUTCHINGS CLARKE. Large 4to. 16 Plates.

WHILE we are inclined to withhold from the mansion here described the epithet "magnificent," bestowed upon it in the title-page itself to the volume, which title has been above abridged by us, we do not, therefore, consider it unworthy of the study Mr. Clarke has devoted to it. On the contrary, we are of opinion that he has performed a laudable task in restoring the building in the drawings he has made of it, and thus preserving a specimen of our ancient domestic architecture, historically interesting and curious, although in itself not one which we ourselves should recommend for direct imitation at the present day; since it belongs to that transition period, when the Tudor style had lost much of its better character, and was gradually sinking down into Elizabethan, and the still more degenerate taste that was in vogue in the time of James.

The elevations are for the most part marked by a heavy formality, and also by monotony; their windows being alike both as to design and dimensions, and similarly disposed throughout on every floor; such, at least, is the case with the east and west sides, which have, moreover, no breaks whatever to give any variety or relief to the flatness of their general aspect. The apertures, again, are so numerous and so large, as to give to the house the appearance of being nearly all windows, too much exposed to cold in winter, and to the sun in summer. The want of variety attending the windows is still further increased by the hood-mouldings of their labellings being continued from one to the other, so that those on each floor are connected

together. In this respect the north, or principal front, is less objectionable; the centre portion being recessed, and the windows above the porch, which comes between that part and one of the extremities, being narrower than the others. Of decoration there is very little, except the pinnacles to the gables, and the shafts of the chimneys. By far the most piquant and picturesque aspect the building presents is that on its south side, where it forms a small court, enclosed by a screen wall, the height of the lower floor, and having at its inner angles octagonal staircase towers rising above the roof, with an extensive and very bold stack of chimneys between them, with others on the sides of the court.

In addition to the other plates, there are two coloured ones, showing the side of a room over the hall painted in fresco, and two compartments of a gallery similarly decorated, or, we ought to say, disfigured, for it is hardly possible to conceive anything in more preposterous taste. It is, indeed, so preposterous, so *outré*, and so truly frightful, that we may spare ourselves the trouble of protesting against it, being fully convinced there is no danger whatever of its finding any imitators, even among the most bigoted admirers of the fantastical mode of embellishment which prevailed during the times of Elizabeth and her successor. By no means, however, do we wish to be understood as censuring Mr. Clarke for introducing these curious specimens: rather do they add to the historical value of his publication, by furnishing a record of the taste of the age to which they belong; and if we seem to have been very sparing of commendation in the course of our remarks, it is because the subject itself belongs to a style we cannot advocate, as we are far from admiring it.

We suspect that Mr. C. chose his present subject in compliance rather with the present demand for specimens of the Elizabethan period, than with his own taste. At any rate, it gives us pleasure to find that he has since directed his attention to something better deserving it, namely, the Collegiate Church of Southwell, in Nottinghamshire, of which he has announced a series of engravings, comprising sections and details, to be published early in the present year, of this church. The nave and transepts are Norman, but the rest is chiefly early English, in which respect Rickman praises it as being one of the best examples in the kingdom. "The chapter-house," he further observes, "is a fine specimen of early decorated work: the tracery of the windows, the stalls under them, and the entrance door, which is double, are all very good The organ-screen and some inferior stalls are of later decorated character, and are peculiarly beautiful. The whole of this church deserves the study due to a cathedral, and though it is not so varied in its styles as some edifices, it claims attention for its purity and good preservation."

The Grand Junction Railway Companion. By Arthur Freeling. Liverpool: Henry Lacey. 1837.

This is a very useful little work, which should be in the hands of every person previously to travelling on the Grand Junction Railway—it describes the route of the line, the engineering works, the distances, and all places worthy of notice in the neighbourhood; it also gives a description of the different conveyances and times of starting at each of the termini; likewise the public buildings and places of amusement.

Irish Collegiate Architecture; with Observations on Architecture in General. By Henry Fulton, Esq. Second Edit. Dublin, 1837.

So very rarely does anything concerning architecture, even though limited to mere intelligence, come from the sister island, that even this pamphlet, small as it is, claims more notice than it might otherwise obtain from us. The title indeed is rather a misnomer, the subject being not collegiate architecture, but a building for a museum and lecture-rooms in the court of Trinity College, Dublin; for which, it seems—for we have never chanced to hear anything of the matter before—architects "from all parts of the world" were invited to send in plans by the 1st of March, 1834, premiums of £70, £40, and £30 being offered for the three best. The writer himself, though only an amateur architect, thought fit on this occasion to submit a design, of which the following is his own account:—

"One of my plans was to erect a classical temple, somewhat in the centre of the Library square, having a Corinthian portico of six disengaged columns facing the grand entrance from College Green, and harmonizing in effect with the fronts of the Chapel and Examination-hall; an imaginary line drawn from the east angle of the west (!) flank of the Library would just clear the front of the temple. From this to the centre point, midway between the doors of the Chapel and Examination-hall, the distance would be 159 ft. 6 in., which is just half the distance of the same line to the College Green entrance. This building was calculated either for a chapel, an examination hall, or lecture-rooms, and exteriorly had some resemblance to, but was not a copy of, the Maison Carrée at Nismes, a model of which was at the same time exhibited."

We omit the rest of the description, which, we are informed, was written in order that readers might compare it with the works now in progress, and doubtless with the view of convincing them that the adopted plan is decidedly inferior to it. We further learn, that there were twenty-three competitors, four of whom were Scotch, two English, and the rest all Irish; also, that the cost was limited to £20,000; yet the estimates varied from £43,000 to £19,000, while some designs had no estimates accompanying them; and of the successful candidates, one subsequently gave in his estimate at £80,000, the other at £38,000. Yet as to what the actual design is, and who the architect employed to carry it into execution, we are left entirely in the dark; all that we can gather from the very confused account here given of the business being, that the first premium was awarded to a Mr. Paine, who, on being required by the Provost to make some alterations in his designs, made also a charge for them which was resisted by the College, till an action being instituted against them, they thought fit to compromise the matter by paying £650! After that, an English architect who had not been a candidate, and whose name is not mentioned, was employed; but he too was dismissed for some one else, whose name the writer has not divulged. All this is certainly a very strange business; but instead of stating it as clearly and explicitly as possible, Mr. Fulton has so mystified it by inuendo, and obscure "round-about-way" remarks, that we cannot make out more than his general drift, namely, that there has been strange mismanagement and blundering throughout the whole business, and the building will be very ill adapted to its situation.

Not knowing the precise *locale*, either in regard to space or the arrangement of the surrounding buildings, we are at a loss to comprehend many of the remarks relative to the situation, although to persons acquainted with it they may be intelligible enough; and instead of being "*bothered*" by the author's attempt at explanation, we, and others in our predicament, might have understood it too, had he given in a small wood-cut, a sketch block-plan of the site and relative situation of the adjacent edifices. What adds not a little to the botheration we complain of is, to find him, after speaking of "the works now in progress" in College-court, saying, that that site has been abandoned, and for no other reason, it would seem, than because he had fixed upon it; and that it is now "projected to make an extended square, of which the library range will form half a side; where, perhaps, we are to have a prison-like edifice in the middle, with a beehive on the top, and the portico of the Roman Pantheon stuck on the centre of its front." Are we to understand by this, that everything has been begun *de novo*, or rather is entirely "at sixes and sevens," and nothing as yet—at least at the time the pamphlet was written—definitively settled upon? We give up the point in despair. The truth is, the writer is a very bad hand at mere matter-of-fact; let us therefore see, whether he be much better in regard to matters of opinion, as he has subjoined "a few remarks on architecture in general," a subject which, he says, he greatly desires to see more studied by his countrymen.

These remarks amount to no more than a mere confession of faith on his part; which leaves no room for suspecting him of being infected with the Gothic heresy when we read, that after the decadence of the art in the age of Diocletian, "then every order, every principle of architecture, was violated and thrown into confusion; every expedient exhausted for the purpose of producing novelty; and strange to say, out of this chaos there arose a style—although eminently characteristic of those violations, charged with meretricious ornament without limit, regardless of all order, trifling and weak in detail, yet magnificent and bold in the aggregate. Such is the style called Gothic—a barbarous term better exchanged for that of Diocletian, out of which it sprung, and to which it bears more resemblance, even with the acquisition of the pointed arch and clustered column, than the Palladian does to the Greek style." This passage throws some new light on the subject, because it shows that we have all along been blundering in calling the style alluded to Gothic, when it should in reality be termed Diocletian; but it is a light that will strike Welby Pugin as a *coup de soleil*, should he ever chance to light upon the book. "Charged with meretricious ornament—trifling and weak in detail!"—for those scandalous expressions Mr. Fulton ought to expect nothing short of immolation from Pugin the pugnacious, the very next time he takes pen in hand; from

"the Goth,
Whose rage for the Gothic is such that it fairly amounts unto wrath."

Neither do we think that John Britton will be much better pleased when he finds that his term Christian architecture, which he flatters himself he has brought into vogue, is now to be exploded, and to make way for the horribly heathenish one of "Diocletian." As for ourselves, why we could forgive him much more, and give him a hearty bravo to boot, in return for the thrust he has directed against that arch-

heresy of all, the Palladian style. He further on declares the Saxon and Tudor styles—which are by-the-by tolerably wide apart from each—and their varieties, to be more commendable than that now called Palladian; for entertaining which opinion it will be well if he escapes without a flagellation from Joseph Gwilt, the sworn champion of Palladianism, and the bitter foe of all amateurs.

Afterwards, we admit, he puzzles us not a little when he says: "As to the erection of public buildings, unfortunately, modern architects, too vain of their own resources, draw little from the treasures the ancients have left us, except a column or a moulding." How they manage matters just now on the other side of the Irish Channel we know not; but we do know that, here at home, it is impossible to accuse our architects of relying too much on their own resources, since for public buildings they rarely do more than help themselves by wholesale to the "treasures of the ancients," as far as they can be made to answer their purpose, without having recourse to their own stock of ideas, unless when their drafts upon the common treasury are returned dishonoured. The writer objects—and so do we—to super-columniation; not, however, on critical grounds, but for the following whimsical reasons—"columns are supposed to represent trees, and cannot with propriety be placed on the top of one another." Where he picked up the notion that columns represent trees we know not; it is an odd idea, pretty near akin to that of old Serlio, if we mistake not, when he compares a chimney to the nose on a man's face. For our part, we have always taken columns to be neither more nor less than columns. Why are columns like trees? would be a more puzzling conundrum than, "Why is the roof of a house like the sun?"—since to that question every child can reply, "Because it has *beams*." And now, having arrived at this very sunny and luminous point in our lucubrations, we may as well vanish like a flash of "the brisk lightning."

Companion to the Almanack, or Year-Book for 1838. London. Knight and Co.

For a series of years this publication has distinguished itself by giving, under the section of "Public Improvements," an historical *précis* and description of the principal buildings erected or commenced within the preceding twelvemonth, so as to form an exceedingly useful and valuable record in regard to the progress of architecture; and, we have no doubt, is so well known as such to most of our readers, as scarcely to require our recommendation. The present volume is, in this respect, quite equal to any of its predecessors; much superior, in fact, to the earlier ones, and contains some ably written descriptions, with not a few exceedingly clever remarks. The fullest accounts are those of the interior of the College of Surgeons, and the Fitzwilliam Museum. There is likewise a very satisfactory one of the Leicester General Newsroom and Library, lately erected from the designs of Mr. W. Flint. Of this subject there is a wood-cut. The other illustrations are the portico of the National Gallery—the principal Front of the Fitzwilliam Museum—the Medical Institution at Liverpool—the Arch before the New Palace—the Oxford and Cambridge Club House—a Plan of the Corn Market and Grey Street, Newcastle—and the Entrance to St. Mary's Cemetery, Liverpool. The idea of showing the portico only of the National Gallery, and the parts immediately adjoining it, appears to us a very excellent one, as that feature is thereby exhibited more distinctly than it would be in a view of very large dimensions, and without more than just the lower portion of the dome being seen, which, though the portico itself is the best, happens, unfortunately, to be the most censurable feature in the whole design.

We are of opinion it would very well answer the publishers' purpose were they now to reprint all the architectural portions of the series, as far as it has proceeded, in a separate pocket volume, with an enlargement of some of the descriptions, and some additional cuts. Such a reprint would not at all interfere with the "Companion" itself; on the contrary, many, we apprehend, would be glad to have all the architectural chapters in a collective and separate form, even though they might happen to have the whole of the "Companion to the Almanack."

The Millwright and Engineer's Pocket Director. By John Bennett, Engineer, &c.

This is a little work containing the prices of machinery and other articles connected with millwork, machinery, engines, &c., together with calculations of the weight of iron, copper, and other metals, and a few useful diagrams, showing how the square, the circle, triangle, and other geometrical figures may be subdivided into proportional parts. The prices, in general, are too high; if they were revised, the work would be very useful to the younger members of the profession.

LITERARY NOTICES.

Dr. Ure has for a considerable period been engaged on "A Dictionary of Arts, Manufactures, and Mining," which is now in the press, and will form one very thick volume, 8vo., illustrated by a large number of engravings on wood, and is intended as a companion to Mr. M'Culloch's "Dictionary of Commerce and Commercial Navigation."

Dr. Arnott, whose "Elements of Physics" have been so eminently popular, has just ready for publication a work "On Warming and Ventilating, with Directions for making and using his Thermometer Stove, or Self-regulating Fire, and other New Apparatus," which he has lately invented.

Mr. Wood's valuable work on "Railroads," which has so long been out of print, will shortly re-appear. The new edition is now in the press. It has been thoroughly revised and corrected, and much enlarged; with an entirely new set of plates and woodcuts.

Mr. John Howard Kyan, Patentee of the Anti-Dryrot Composition, is about to publish a work "On the Elements of Light, and their Identity with those of Matter, Radiant and Fixed."

Mr. H. Lacey is about to publish, in a pocket volume, under the sanction of the Company, "A London and Birmingham Railway Companion," on the plan of, and by the same Author as "Freeling's Grand Junction Railway Companion."

Mr. Williams is preparing for publication a valuable work "On Bridges," which, we are happy to hear, is to be edited by Mr. Macneill, C.E., &c.

An Elementary Course of CIVIL ENGINEERING. *By* D. H. Mahan, *Professor of Military and Civil Engineering in the United States' Military Academy.**

The general series of operations preliminary to establishing a line of internal communication, whether it be a road, a canal, or a railroad, is the same in all cases, and consists, in the first place, of a *reconnaissance*, or examination of the country between the two points to be connected by the line, for the purpose of ascertaining the most favourable direction pointed out by the natural features of the country; and, in the second place, of an accurate survey of the various lines which have been fixed upon by the reconnaissance, in order to compare their relative advantages.

Reconnaissance.—In taking into view any considerable extent of country, two remarkable features immediately present themselves, which are the valleys of the water-courses, and the high grounds by which these valleys are separated. Each of these features would seem, at first sight, to present an endless variety of forms and combinations; but, upon more careful inspection, it will be found, that the more considerable valleys are the main channels, or drains, for others of a secondary character, whilst these, in their turn, perform the same functions for others of a still smaller class, and so on, in the descending order of progression, from those immense basins which receive the waters of the largest rivers, to the scarcely distinguishable furrows of the most trifling rills. A similar order of progression will be found to hold with respect to the high grounds, in descending, by successive degrees, from those lofty chains which separate valleys of the first order, to the spurs which, proceeding from their sides, divide the secondary valleys, and throw out in their turn others of an inferior order, which separate the tributaries of the secondary valleys, and are themselves the main stems of a still inferior order.

Two remarkable classes of lines present themselves in connexion with these natural features; they are the water-courses, which form the lowest lines of the valleys; and the dividing ridges, which are the highest lines of the main chains and spurs; and each of these classes possess the remarkable properties of being lines of greatest declivity of the surfaces to which they belong.

From this glance at the general configuration of any portion of the earth's surface, it will readily appear, that lines of communication admit of a division into two classes: 1. Those which connect two points of the same valley; 2. Those which connect two points separated by a dividing ridge. And as one of the principal conditions which every line of communication should satisfy is to connect the two points by the shortest practicable route, it will also readily appear from what has been said, that this condition will be satisfied for the first class of communications, by following a direct line between the two points, since the level between the two does not admit of reduction; whereas, in the second class, the line must not only be as direct as practicable between the two points, but must also pass the dividing ridge at the lowest level between them, in order to effect all possible reduction in the height between the two points and that in which the line crosses the ridge.

It is, therefore, a subject of importance to be able, by a simple reconnaissance, to ascertain the lowest point of a dividing ridge between any two points, since it will abridge the labour of the succeeding operations.

In the common maps of every portion of a country, it will be found that the water-courses are usually laid down with sufficient accuracy to shew the direction in which the valleys lie; that of the rising grounds by which they are separated, and even the approximate position of the ridges. With these approximate data the engineer is furnished with a guide to direct him to the points which present the greatest probability of a favourable result. For there exists a necessary co-relation between the water-courses and ridges, as the lines of greatest declivity of the surfaces to which they belong, from which the highest and lowest points of those surfaces can be readily determined. A few familiar illustrations will serve to place this in a clear point of view,

* Published at New York by Wiley and Putnam.

without entering into the strictly mathematical reasoning upon which it rests.

From the physical facts of water always seeking what is commonly termed its lowest level, and that by the shortest line, or the line of greatest declivity of the surface along which it flows, it follows, that the water-courses mark out the lowest points of the valleys, and are also their lowest lines of greatest declivity. If, then, on a map of any portion of a country, it be found that the water-courses all diverge from, or converge towards one point, it will indicate, without farther examination, that this point is in the first supposition the highest, and, in the second, the lowest point of that portion of country.

If two water-courses flow in opposite directions from a point, it will indicate that this is the lowest point of the ridge of the rising ground by which their valleys are separated; for, from what has just been laid down, the ridge must evidently decline on both sides to this point.

If two water-courses flow in the same direction and parallel to each other, it will simply indicate a general inclination of the ridge between them, in the same direction as that of the water-courses. The ridge, however, may present in its course elevations and depressions, which will be indicated by the points in which the water-courses of the secondary valleys, on each side of it, intersect each other on it; and these will be the lowest points at which lines of communication, through the secondary valleys, connecting the main water courses, would cross the dividing ridge.

If two water-courses flow in the same direction, and parallel to each other, and then at a certain point assume divergent directions, it will indicate that this is the lowest point of the ridge between them.

If two water-courses flow in parallel but opposite directions, there is nothing to indicate the direction of the inclination of the ridge between them, if any exists; but the meeting of the water-courses of the secondary valleys on the ridge, or an approach towards each other at any point of the two principal water-courses, will indicate the points of depression in the ridge.

Survey.—The surveys which succeed the reconnaissance consist of several *trial lines* between the points, fixed upon in the reconnaissance, which are generally run with the chain and compass, and are then levelled with the spirit level throughout their entire extent, for the purpose of determining the undulations of the ground along the lines. Besides the longitudinal levels, a series of cross levels are made, at equal distances apart, perpendicular to the directions of the trial lines, in order to show the inclination of the ground, on each side of the trial lines, for a width greater than that which the line of communication will probably occupy.

Map and Report.—After these surveys are made with all desirable accuracy, a map, exhibiting the topographical features of the ground, and the profiles in the direction of the different levels, is carefully drawn up from the notes taken on the ground. As there are many other points, upon which accurate information is desirable in such cases, that cannot be shown on the map, it should be accompanied by a descriptive report, in which should be set forth the character of the natural features of the country along the lines which are deemed favourable or otherwise to the construction of the road, as the nature of the soil, that of the water-courses, &c. &c.

Survey for a Road.—In laying out a common road, the engineer is less restricted in the direction of his line than in any other kind of communication, owing to the character of the conveyance used upon it; nevertheless he should confine himself, as far as economy of expenditure will permit, to the most direct line between the two points, and the one which offers the least height to be overcome. The obstacles with which he will meet to prevent this are hills, valleys, marshes, and water-courses.

When a hill intervenes between the two points to be connected, the principal object to be attended to, is to give the road such a slope, that in the descent with the usual speed there shall be no danger to the carriages from the accelerating force of gravity in the direction of the road; and this will be accomplished by not making the slope greater than what is termed *the angle of friction* for the particular kind of a road covering used, whether it be a pavement, a broken stone surface, or a gravel road. For when the slope of the road is equal to the angle of friction, the friction of the carriage wheels will be in equilibrium with the component of the force of gravity in the direction of the road, and this component will, therefore, have no tendency to increase the velocity of the carriage, which it would do were it greater than the force of friction, as the difference between the two forces would then act as an accelerating force on the carriage.

To determine the angle of friction, direct experiments have been made, by allowing carriages to descend freely on a road of variable inclination until the friction overcame the force which caused the motion; and also by the *force of traction* on a level road, or the fractional part of the weight of the carriage which, when applied to it, would be just sufficient to overcome the friction and set the carriage in motion.

The following are the results of those experiments, the load moved being one ton, or 2240 pounds.

No. 1.	Well made pavement	33 lbs.
2.	Broken stone surface laid on an old flint road . .	65 „
3.	Gravel road	147 „
4.	Broken stone surface on a rough pavement bottom .	46 „
5.	Broken stone surface on a bottom of beton . . .	46 „
6.	Railways	8 „

From this it appears that the angle of friction, in the first case, is represented by $\frac{33}{2240}$, or $\frac{1}{68}$ nearly; and that the slope of the road should therefore not be greater than one perpendicular to sixty-eight in length, or that the height to be overcome must not be greater than one sixty-eighth of the distance between the two points measured along the road, in order that the force of friction may counteract that of gravity in the direction of the road.

A similar calculation will show that the angle of friction, in the other cases, will be as follows:—

No. 2.	1 to	35 nearly.
3.	1 „	15 „
4 and 5 . . .	1 „	49 „
6.	1 „	280 „

In laying out, therefore, a road, when one point is higher than another, or when it is necessary to pass a ridge at a point higher than either of the extreme points, the line followed should be direct between the two points, so long as the ascent is within the foregoing limits, according to the character of the road covering, and no other obstacles intervene which would render necessary a change of direction. If, owing to any of these causes, a change of direction should become necessary at any point, it will be made, and be continued in the new direction until the direction towards the point of arrival can be resumed. An examination of the line, between the point where the original direction is resumed, and the first point, will remain to be considered in comparison with those already laid out.

In all cases, so far as it can be done with a due regard to economy in the outlay of construction, a uniform ascent should be obtained between the points of departure and arrival, to avoid useless ascents and descents, which occasion a loss of power. Cases of this character not unfrequently present themselves; as for example, where the points of departure and arrival, lying on opposite sides of a hill, can be connected by a straight line by crossing the ridge at a level higher than either of the points; or else by taking a circuitous direction around the base, by which the ascent between the two would be made uniform. In such cases the choice of the engineer must be governed by his judgment, founded on a comparison of the expense of the two lines, and the advantages which they severally offer with respect to the time and means of conveyance.

A uniform ascent within the prescribed limits can always be obtained, whenever there is a continual rise of the ground between the point of departure and the point where the road crosses the ridge, by making frequent changes of direction in a zigzag line between the two points. The length of each zigzag will depend on the nature of the surface, and will in no manner affect the total length of the road if the ascent be uniform; for it is a property of lines of the same inclination which connect two different levels to be of the same length, whatever change of direction the lines may assume.

It may be stated in this place, that the straight portions of the line are connected at the points of change of direction by an arc of a circle tangent to the two lines which it connects. This curved part should not be so abrupt as to require any considerable diminution of speed in the carriage whilst passing over it, and, as a farther precaution for safety in descents, the slope of the road at these points should be less than along the straight portions of the line.

When a valley intervenes between the two points, the same principles should guide the engineer in the choice of his line as in the case of a hill; for the valley must be descended on the side towards the point of departure to be ascended on the opposite side; and the ascent and descent should be as uniform as practicable, and in no part greater than the limits already laid down.

The case may also here present itself, whether it will be best to pursue the direct line between the two points, or to deviate from it, by crossing the valley at a higher level nearer the head of it, by a more circuitous line. Other cases may present themselves where the width of the valley, being much less at some lower level, might offer a great economy in the embankments; or, finally, where undulations in the ground, if taken advantage of, would produce the same effect, by cutting down a portion of the elevated parts to fill up the depressions between them. All of these cases require careful examination before any line between the points is definitively adopted.

When a marshy or very wet soil intervenes between the points, it will generally be best to change the direction of the line to avoid crossing it, owing to the difficulty of obtaining a firm bottoming for the road covering in such localities, which can only be effected by a thorough system of drainage.

When a water-course intervenes between the points, the point at which the line should intersect it will depend on the character of the stream, and that of the approaches to it; as both economy of construction, and safety to the structure over which the road is carried, may designate some other point than that in which the direct line intersects the water-course.

As the general direction of a road will usually be the same as the valleys of the water-courses between the points of departure and arrival, the advantages presented by both sides of the valley for constructing the road should be carefully balanced. The principal favourable points are few secondary water-courses intersecting the line of the road, a firm soil, a free exposure of the road surface to the action of the sun and wind, and facilities for procuring the necessary materials to form the road covering.

A careful comparison of the surveys of the different trial lines will usually enable the engineer to decide, without farther labour, upon the one which combines the most desirable advantages.

Equalizing the Excavations and Embankments, &c.—The next important point to be adjusted is *balancing*, or *equalizing* the excavations and embankments; that is, to make such a disposition of the slopes, and such partial changes in the main direction of the line, that the parts which will require to be excavated shall furnish just sufficient earth to form those portions which must be filled in. The solution of this problem, in the cases which most usually occur in practice, is of a very indeterminate character, and the engineer is obliged to resort to a system of successive approximations, by assuming different slopes within the prescribed limits, and by shifting the position of the line to the right or left, until he arrives at the most favourable

result. In conducting these trials, the whole line should be subdivided into several portions, and the equalization of these portions should be attempted independently of each other, instead of trying a general equalization throughout the entire line.

In balancing the excavations and embankments, their solid contents are calculated, by subdividing them into the most simple geometrical solids, such as prisms, prismoids, wedges, and pyramids, whose solidities can be determined by the ordinary rules for the mensuration of solids. This subdivision will present but little difficulty when a sufficient number of cross profiles have been taken. Each cross profile will present a quadrilateral, or a triangular figure, of which the line of the roadway, the side slopes, and the line of the surface of the ground, will form the sides. The three first will be right lines, and the last a curved line, but generally of such slight curvature that it may be regarded as a right line. The same remark may be made with respect to the surface of the ground, which, although in fact a curved surface, may be regarded as a plane surface, between any two of the consecutive planes of the profiles, provided these profiles be not taken too far apart. This manner of regarding the surface of the ground, will only give an approximate result in calculating the contents of the solids; but this approximation will be sufficiently accurate for all practical purposes, and will avoid more complicated methods, which, although more rigorous in their results, are less suited to the solution of problems of this nature.

In determining the relations between the volumes of the embankments, and the excavations by which they are to be furnished, it must also be borne in mind, that earth in its natural state occupies less space than when broken up; and as the embankments when first formed are in the state of earth newly broken up, an allowance must be made according to the nature of the soil. This allowance will generally vary between one twelfth and one eighth; that is, earth when first broken up will occupy from one twelfth to one eighth more bulk than it does in its natural state.

After the excavations and embankments are equalized, the changes caused by the operation in the *direction of the line* are laid down on the map previously to lying out the line on the ground. This operation is performed by running the new line as laid down on the map, and marking the middle line, or *axis* of the road, by stakes or pickets, placed at equal intervals apart, and numbered to correspond with the same points on the map. The width of the roadway, and the lines on the ground, corresponding to the side slopes of the excavations and embankments, are laid out in a similar manner by stakes, placed along the lines of the cross profiles.

Besides the numbers marked on the stakes to indicate their position on the map, other numbers, showing the depth of the excavations, or the height of the embankment from the surface of the ground, accompanied by the letters *Cut. Fill.* to indicate a *cutting* or a *filling*, as the case may be, are also added, to guide the workmen in their operations. The positions of the stakes on the ground, which show the principal points of the axis of the road, should, moreover, be laid down on the map with great accuracy, by ascertaining their bearings and distances from any fixed and marked objects in their vicinity, in order that the points may be readily found, should the stakes be subsequently misplaced.

Detailed maps of the different divisions of the road, made to a suitable scale, should accompany the general map. The object of these maps being to give, with the utmost accuracy, the longitudinal and cross sections of the natural ground and the road way, by exhibiting all the parts of the road surface, and of the excavations and embankments, with the horizontal dimensions of all the parts, and the vertical heights of the different points above one general plane of level, termed the *plane of comparison*, numbered with great care.

Detailed drawings of the road covering, of the masonry and carpentry of the bridges, culverts, &c., to which are added written *specifications* of the manner in which the embankments, excavations, masonry, &c., is to be executed, should accompany the division maps, to guide the superintending engineer of the division in the performance of his duties.

Before breaking ground, to commence the *grading*, or forming the excavations and embankments, another problem of a very intricate character, which has occupied the attention of the first mathematicians, and has called into play all the resources of the higher analysis, remains to be solved. This is the removal, and the disposition of the different volumes so as to present the greatest economy in transportation and expense. The results which have been arrived at in the different cases which have been treated, seldom present themselves in practical operations. There is, however, one general principle which is applicable to all cases, which is, that to make the transportation a minimum between the points from which the earth is taken, and that where it is deposited, the lines passed over by the centre of gravity of all the particles must neither cross each other in a horizontal, nor in a vertical direction. To apply this principle to practice, the entire volumes of the embankments and excavations should be subdivided into several others, by planes in the direction of the transportation, and these partial solids should be removed within the boundaries marked out by these planes. The farther the subdivision is carried, the greater will be the accuracy of the result.

Grading.—In forming the excavations, the inclination of the side slopes demand peculiar attention. This inclination will depend on the nature of the soil, and the action of the atmosphere and internal moisture upon it. In common soils, as ordinary garden earth, formed of a mixture of clay and sand, compact clay and compact stony soils, although the side slopes would withstand very well the effects of the weather with a greater inclination, it is best to give them two base to one perpendicular, as the surface of the roadway will, by this arrangement, be well exposed to the action of the sun and air, which will cause a rapid evaporation of the moisture on the surface. Pure sand and gravel may require a greater slope according to circumstances. It is not usual to use any artificial means to protect the surface of the side slopes from the action of the weather; but it is a precaution which, in the end, will save much labour and expense in keeping the roadway in good order. The simplest means which can be used for this purpose, consist in covering the slopes with good sods, as shown in fig. 1, or else with a layer of vegetable mould about four inches thick, carefully laid and sown with grass seed. These means will be amply sufficient to protect the side slopes from injury when they are not exposed to any other causes of deterioration than the wash of the rain, and the action of frost on the ordinary moisture retained by the soil.

Fig. 1.

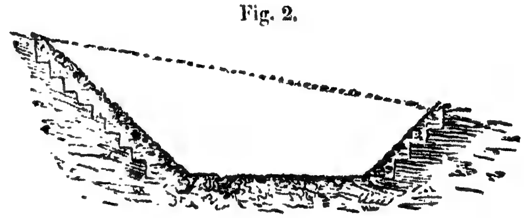
When the side slopes are not protected in this manner, it will be well, in localities where stone is plentiful, to raise a small wall of dry stone at the foot of the slopes, to prevent the wash of the slopes from being carried into the roadway.

A covering of brush-wood, or a thatch of straw, may also be used with good effect; but, from their perishable nature, they will require frequent renewal and repairs.

In excavations through solid rock, which does not disintegrate on exposure to the atmosphere, the side slopes might be made perpendicular; but as this would exclude in a great degree the action of the sun and air, which is essential to keeping the road surface dry and in good order, it will be necessary to make the side slopes with an inclination, varying from one base to one perpendicular, to one base to two perpendiculars, or even greater, according to the locality; the inclination of the slope on the south side in northern latitudes being greatest, to expose better the road surface to the sun's rays.

The slaty rocks generally decompose rapidly on the surface when exposed to moisture and the action of the frost. The side slopes in rocks of this character may be cut into steps, as shown in fig. 2, and then be covered by a layer of vegetable mould sown in grass seed, or else the earth may be sodded in the usual way.

Fig. 2.

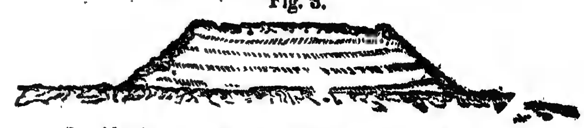


The stratified soils and rocks, in which the strata have a *dip*, or inclination to the horizon, are liable to *slips*, or to give way by one stratum becoming detached and sliding on another, which is caused either from the action of frost, or from the pressure of water, which insinuates itself between the strata. The worst soils of this character are those formed of alternate strata of clay and sand, particularly if the clay be of a nature to become semi-fluid when mixed with water. The best preventives that can be resorted to in these cases, are of adopt a thorough system of drainage, to prevent the surface water of the ground from running down the side slopes, and to cut off all springs, which run towards the roadway from the side slopes. The surface water may be cut off by means of a ditch (fig. 1) made on the up-hill side of the road, to catch the water before it reaches the slope of the excavation, and convey it off to the natural water-courses most convenient, as in almost every case it will be found that the side slope on the down-hill side is, comparatively speaking, but slightly affected by the surface water. To cut off the springs, it will be necessary to sink a ditch, or drain, on the side of the road from which the water flows, sufficiently deep to intercept the springs, and to fill this drain with broken stone loosely thrown in, to offer an easy water way, and to prevent the drain from filling in with earth. The drain, thus arranged, must have an outlet towards some natural water-course.

Neither of these precautions, however, will suffice in some cases where the soil is very loose, or is of a marly or chalky character: and all that can be done will be to give the wash a wide berth, and to allow the side slopes to assume with time their natural inclination, removing the fragments of the slips as they are deposited at the foot of the slope, except such as may form a kind of buttress for the slopes.

In forming the embankments, as shown in fig. 3, the side slopes should be made with a less inclination than that which the earth naturally assumes, for the purpose of giving them greater durability, and to prevent the width of the top surface, along which the roadway is made, from diminishing by every change in the side slopes, as it would were they made with the natural slope.

Fig. 3.



To protect the side slopes more effectually, they should be sodded or sown in

grass seed, and the surface water of the top should not be allowed to run down them, as it would soon wash them into gullies, and destroy the embankment. In localities where stone is plenty, a sustaining wall of dry stone may be advantageously substituted for the side slopes.

To prevent, as far as practicable, the settling which takes place in embankments, they should be formed with great care; the earth being laid in successive layers of about four feet in thickness, and each layer well settled with beetles. As this method is very expensive, it is seldom resorted to, except in works which require great care, and are of trifling extent. For extensive works, the method usually followed, on account of economy, is to embank out from one end, carrying forward the work on a level with the top surface. In this case, as there must be a want of compactness in the mass, it would be best to form the outsides of the embankment first, and to gradually fill in towards the centre, in order that the earth may arrange itself in layers with a dip from the sides inwards; this will in a great measure counteract any tendency to slips outwards.

A common method also, but a very bad one, is to make what is termed a *side forming*, which is done by raising the whole embankment at once, commencing at one side and filling towards the other. This method is only used when the road is partly in cutting and partly in filling; it is unstable, and the earth settles greatly and is liable to slips.

Besides the necessary embankments for the road surface, there are others termed *spoil banks*, which consist of the surplus earth from excavations that is deposited in some convenient locality as near to the point from which the earth is taken as safety to the side slopes of the excavation will permit. The spoil banks are generally formed parallel to the roadway, and some feet back from the top of the side slopes, to prevent the weight of the mass from crushing in the side slope. The down-hill side will, in most cases, be the most suitable locality; and, if it be thought necessary, a slight surface drain may be placed at the foot of the slope, towards the road, to prevent the water from the spoil bank from making its way to the side slope of the excavation.

In the cases of what are termed *side cuttings*, where the roadway is partly in excavation and partly embankment, the formation of the side slopes and excavations and embankments, with the precautions to preserve them from damage, will be arranged as has already been explained. But if the inclination of the natural surface of the ground on which the embankment rests is so great as to endanger its stability, it will be necessary to form the surface into steps, as shown in fig. 4, to give the embankment a stable bed.

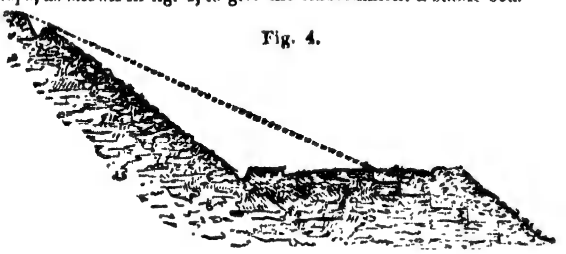


Fig. 4.

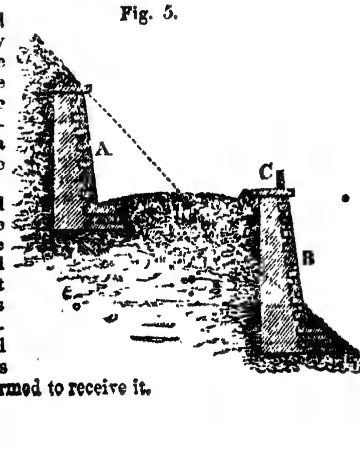
In side cuttings along a natural surface of great inclination, the method of construction just explained will not be sufficiently secure, and sustaining walls must be substituted for the side slopes, as shown in fig. 5, both of the excavations and embankments. These walls may be made simply of dry stone, when the stone can be procured in blocks of sufficient size to render this kind of construction of sufficient stability to resist the pressure of the earth. But when the blocks of stone do not offer this security, they must be laid in mortar, and hydraulic mortar is the only kind which will form a safe construction. The batter of the walls may vary between twenty-four perpendicular to one base, and six perpendicular to one base. It should never be less than this latter, otherwise the mortar between the joints near the surface will be washed out by the rain, and the seeds of vegetables lodging in the voids will germinate, and in a short time destroy the adhesion between the mortar and stone by the penetration of their roots between them. The wall A which supplies the slope of the excavation should be carried up as high as the natural surface of the ground; the one B that sustains the embankment, should be built up to the surface of the roadway; and another wall C, of less thickness and about four feet high, termed a *parapet wall*, should be raised upon it to secure vehicles from accidents in passing from the line of the roadway.

Fig. 5.



A road may be constructed partly in excavation and partly embankment along a rocky ledge by blasting the rock, when the inclination of the natural surface is not greater than one perpendicular to two base; but with a greater inclination than this, the whole should be in excavation.

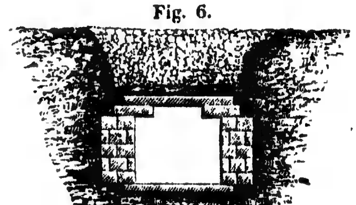
There are examples in road constructions, in localities like the last, supported on a frame work, consisting of horizontal pieces, which are firmly fixed at one end by being let into holes drilled in the rock, and are sustained at the other by an inclined strut underneath, which rests against the rock in a shoulder formed to receive it.

Drainage.—A system of thorough drainage, by which the water that filters through the ground will be cut off from the soil beneath the roadway, to a depth of at least three feet below the bottom of the road covering, and by which that which falls upon the surface will be speedily conveyed off, before it can filter through the road covering, is essential to the good condition of a road.

The surface water is conveyed off by giving the surface of the roadway a slight transverse convexity from the middle to the sides, where the water is received into the gutters, or *side channels*, from which it is conveyed by under-ground aqueducts termed *culverts*, built of stone or brick, and usually arched at top, into the main drains that communicate with the natural courses. This convexity is regulated by making the figure of the profile an ellipse, of which the semi-transverse axis is 15 feet, and the semi-conjugate axis nine inches; thus placing the middle of the roadway nine inches above the bottom of the side channels. This convexity, which is as great as should be given, will not be sufficient in a flat country to keep the road surface dry; and in such localities, if a slight longitudinal slope cannot be given to the road, it should be raised, when practicable, three or four feet above the general level, both on account of conveying off speedily the surface water, and to expose the surface better to the action of the wind.

To convey the water from the subsoil in a level country, ditches termed *open side drains*, are made parallel to the axis of the road, and at some feet from it on each side. The bottom of the side drains should be at least three feet below the road covering; their size will depend on the nature of the soil to be drained. In a cultivated country the side drains should be on the field side of the fences.

Fig. 6.



As open drains would be soon filled up along the parts of a road in excavation by the washings from the side slopes, covered drains, built either of brick or stone, must be substituted for them. These drains (fig. 6) consist simply of a flooring of flagging stone or of brick, with two side walls of rubble, or brick, which support a top covering of flat stones, or of brick, with open joints of about half an inch, to give a free passage way to the water into the drain. The top is covered with a layer of brushwood and clean gravel, or broken stone in small fragments is laid over this, for the purpose of allowing the water to filter freely through to the drain, without carrying with it any earth or sediment which might in time accumulate and choke it. The width and height of covered drains will depend on the materials of which they are built, and the quantity of water to which they yield a passage.

Besides the longitudinal covered drains in cuttings, other drains are made under the roadway which, from their form, are termed *cross mitre drains*. Their plan is in shape like the letter V, the angular point being in the centre of the road, and pointing in the direction of its ascent. The opening of the angle should be so regulated, that the bottom of the drain shall not have a greater slope along either of its branches, than one perpendicular to one hundred base, to preserve the masonry from damage by the current. The construction of mitre drains is the same as the covered longitudinal drains. They should be placed at intervals of about 60 yards from each other.

In some cases surface drains, termed *catch water drains*, are made on the side slopes of cuttings. They are run up obliquely along the surface, and empty directly into the cross drains which convey the water into the natural water-courses.

When the roadway is in side cutting, cross drains of the ordinary form of culverts are made, to convey the water from the side channels and the covered drains into the natural water-courses. They should be of sufficient dimensions to convey off a large volume of water, and to admit a man to pass through them, so that they may be readily cleared out or even repaired without breaking up the roadway over them.

The only drains required for embankments are the ordinary channels of the roadway, with occasional culverts to convey the water from them into the natural water-courses. Great care should be taken to prevent the surface water from running down the side slopes, as they would be soon washed into gullies by it.

Very wet and marshy soils require to be thoroughly drained before the roadway can be made with safety. The best system that can be followed in such cases, is to cut a wide and deep open main drain on each side of the road, to convey the water to the natural water-courses. Covered cross drains should be made at frequent intervals to drain the subsoil of the roadway. They should be sunk as low as will admit of the water running from them into the main drains, by giving a slight slope to the bottom each way from the centre of the road to facilitate its flow.

Independently of the drainage for marshy soils, they will require, when the subsoil is of a spongy elastic nature, an artificial bed for the road covering. This bed may, in some cases, be formed by simply removing the upper stratum to a depth of several feet, and supplying its place with well packed gravel, or any soil of a firm character. In other cases, when the subsoil yields readily to the ordinary pressure that the road surface must bear, a bed of brushwood, from 9 to 18 inches in thickness, must be formed to receive the soil on which the road covering is to rest. The brushwood should be carefully selected from the long straight slender shoots of the branches of undergrowth, and be tied up in bundles termed *fascines*, from 9 to 12 inches in diameter, and from 10 to 20 feet long. The fascines are laid in alternate layers crosswise and lengthwise, and the layers are either connected by

pickets, or else the withes, with which the fascines are bound, are cut to allow the brushwood to form a uniform and compact bed.

This method of securing a good bed for structures on a weak wet soil has been long practised in Holland, and experience has fully tested its excellence.

Minutes of Proceedings of the Institution of Civil Engineers, containing Abstracts of Papers, and of Conversation for the Session of 1837.

(Continued from Page 79.)

"May 2, 1837.—The President in the Chair.

"The Ordnance Maps of England and Wales were received from the Master-General and Board of Ordnance, and the President announced that, by the munificence of Mrs. Chapman, the Institution was to be made the depository of all the professional plans and papers of the late William Chapman, of Newcastle.

"Mr. Harrison presented a drawing of the Drops at South Shields, erected by himself, and gave an account of the method of working them.

"Some remarks were made on the various methods which had been employed for representing the nature of a country as to levels and slopes. In one map of Warsaw the level of every point was shown; in the Ordnance maps of France the heights of most principal points above the level of the sea are noted. With respect to slopes, different degrees of shading might be used advantageously for mountain ground, the gentle inclinations being lightly and the steep places deeply shaded. In some Prussian maps they had represented mountain ground by circular lines at assigned distances, the lines being very near for considerable slopes. An objection to this plan is, that an engraver aims at a degree of accuracy which he can rarely arrive at; he cannot easily possess sufficient data to put the lines all round a mountain with any tolerable degree of accuracy.

"'*On the Velocity of the Water in Belfast Harbour, by William Bald, Civil Engineer, F.R.S.E., M.R.I.A.*'

"The Bay of Belfast, or Belfast Lough, is about eleven miles long by three broad, and has a depth of water varying from two to eight fathoms at low tide. The bottom consists of mud, and is an excellent holding ground. The mean of thirteen observations assigns the low-water line of spring tides, during the months of January and February last, at *two* feet above the sill of the gate of the new Graving Dock.

"The waters of the river Laggan, fed by a basin whose area is 200 square miles, are discharged into Belfast Bay. The average quantity of rain annually is about 36 inches; *assuming that one third of this falls into the sea by the Laggan river*, the quantity will be equal to *one foot* of depth over the whole basin. The mean daily quantity will be somewhat more than fifteen million cubic feet per day. This is the power combined with the tidal water to keep open the Channel of Belfast.

"On a map accompanying this paper are delineated the velocities of the ascending and descending currents at different states of the tide and parts of the channel.

"Mr. Harrison gave, at the request of the President, some information respecting the fuel and fire-boxes of the locomotives on the Stanhope and Tyne Railway. From long experience they found that coal, which contains much bitumen, causes the tubes of the fire-boxes to leak in a very short time. They obtained coal as free from sulphur as possible, and the consequences had been most advantageous; for during two years and a half not more than 120 tubes had been required for seven engines, of which four were always at work. The tubes were of copper, and $1\frac{5}{8}$ inch in diameter. The usual speed about ten miles an hour. One engine weighing ten tons on six wheels takes 128 tons of coal. The consumption of fuel is $2\frac{1}{10}$ lbs. of coal per ton of goods per mile. The gross load is more than double the weight of the goods. The cheapness at which they carried was to be attributed to the low speed.

"Mr. Carneghie, in reply to a question from the President, stated, that the Stone Planing Machine had not answered for sharp sand stone; but by endeavouring to imitate the mason's tool, and making the machine work in the same manner as the mason, they had succeeded completely. This tool was a comb with teeth, and curiously enough he had found at Dresden a tool which had been in use from time immemorial exactly similar to that which they had adopted.

"May 9, 1837.—The President in the Chair.

"'*On the application of Steam as a moving Power, considered especially with reference to the reported duties of the Cornish and other Engines. By G. H. Palmer, M. Inst. C.E.*'

"In this paper Mr. Palmer first considers the maximum duty which can be done by atmospheric steam, and then, by reasoning analogically from certain theories, some of which are recognised as established, he infers that highly elastic steam, worked expansively, cannot be as economical as atmospheric steam. The reasoning by which the first question, namely, the amount of duty done, is treated, is as follows:—One bushel, that is 84 lbs. of coal, will convert 12 cubic feet of water into atmospheric steam, or each cubic foot of water is made to occupy 20,328 cubic feet. This may be applied directly to raise a column of water, say 35 feet high; that is, 84 lbs. of coal will, in the absence of all friction, be effective for raising 20,328 cubic feet of water 35 feet high; that is, 1,270,500 lbs. 35 feet high, or 44,573,375 one foot high. Making then the usual deduction of 4-10ths for friction, according to Tredgold's calculations, we have about 26,000,000 lbs. as the effective duty of the atmospheric steam produced by 84 lbs. of coal.

"Mr. Palmer having ascertained the maximum duty of 84 lbs. of coal, proceeds to infer that high pressure steam, worked expansively, must be less efficient than this; and the reasoning by which he arrives at this conclusion is founded on the following theories:—

1°. That the sum of the latent and sensible heat is a constant quantity.

2°. That all matter, steam of course included, evolves caloric on compression, and absorbs caloric on dilation.

3°. That equal quantities of water will always require equal quantities of fuel to convert it into atmospheric steam; but though equal weights of water must absorb equal increments of caloric when atmospheric steam is generated, it does not follow that all the caloric absorbed in high pressure steam is exclusively supplied by the fuel expended.

4°. That steam of two or more atmospheres elasticity does not contain two or more times the quantity of water contained in atmospheric steam, but contains proportionably less water as the pressure under which it is generated is increased.

"The preceding principles are illustrated, explained, and insisted on in great detail, and the author infers from them that the high pressure steam generated by one bushel of coal cannot, when worked expansively, perform more duty than atmospheric steam, unless, as is premised in the earlier part of the paper, more than $62\frac{1}{2}$ lbs. of water can be converted by 7 lbs. of coal from 40° Fahrenheit to atmospheric steam, and unless steam can dilate without converting sensible into latent caloric.

"May 23, 1837.—The President in the Chair.

"The paper by Mr. G. H. Palmer, commenced at the last meeting, having been concluded, a discussion took place on the duties of Engines. The question was asked, whether the water raised had been actually measured, and whether the calculations were not made from the known contents of the working barrel. It was the opinion of several present that the duties had always been ascertained in the latter manner. An engine in which the Cornish system is adopted, near London, has a duty of fifty millions, and the Cornish system of clothing was considered as effecting a very considerable saving in fuel.

"'*Account of some Blasting operations through the white Limestone on the Antrim Coast Road, in the north of Ireland; by William Bald, Civil Engineer, M.R.I.A., F.R.S.E.*'

"In the commencement of the paper, the nature of the Antrim Coast and of the white limestone, and the method of blasting, are briefly described. This limestone is similar to the chalk of England in the flints which it contains, but it is exceedingly indurated. From the results of the blasting of several large masses of rock, it appears that *one* ounce of powder will rend 14·12 cubic feet of this limestone when in blocks; whereas the same quantity of powder was required for 11·75 cubic feet of loose whinstone blocks. The specific gravity of the white limestone is very nearly 2·760, and of whinstone or basalt about 3·200. The induration of white limestone may be estimated from the fact, that two men will bore *one* foot deep in half an hour, the diameter of the augers or jumpers being from $1\frac{5}{8}$ to 2 inches.

"A table is given exhibiting the diameter of the auger or jumper used, and the number of inches of gunpowder put in—*one* pound of gunpowder occupies *thirty* cubic inches. The force of the explosion of gunpowder is assumed to be as the cube of the line of least resistance; if the *one* oz. of gunpowder will open a distance of 1 foot of rock, 2 feet would require 8 oz., and 10 feet 1000 oz. There will be some difficulty in ascertaining the line of least resistance in stratified rocks, since the rock may be fissured, or some bed or opening may lie near to the line bored; but the hypogene rocks, as granite and sienite, lying in compact unstratified masses, present no such difficulty.

"The paper is accompanied by drawings and sections, showing the mode pursued in blasting down high cliffs, by boring at the *toe* of the rock; the peculiar character of the veins commonly called scull veins, from their strong resemblance to the sutures of the scull, which traverse the blocks of white limestone; and concludes by expressing the importance of collecting accounts of the quantity of gunpowder consumed per cubic yard in blasting the various kinds of granite, sandstone, &c.; also the diameter of the augers or jumpers; the depths bored, and the quantity of gunpowder the most effective.

"May 30, 1837.—The President in the Chair.

"'*On the results obtained by Mr. G. H. Palmer, respecting the Maximum Duty of a given quantity of Atmospheric Steam; by Thomas Webster, M.A., Sec. Inst. C.E.*'

"The object of this paper was to show, that the result obtained by Mr. Palmer, in his paper on Steam, read at the two previous meetings of the Institution,* coincides very accurately with the authenticated accounts of the best Watt engines. In the calculation made by Mr. Palmer, no account is taken of the heat rescued by employing over again the hot water. This, considering the relative quantities of latent and sensible caloric in steam, may be taken at one-sixth; and being taken into the account, we may consider that, on the principles laid down by Mr. Palmer, the duty done by a Watt engine ought to be about thirty-two millions.

"The next question is, what amount of saving is to be attributed to the system of clothing adopted in the Cornish engines. This it is stated may change the data entirely; the quantity of water evaporated may be very different; the quantity of heat saved and worked over again incalculable; at

---

* See *Minutes*, May 16 and 23.

present then we cannot apply any principles of theoretical calculation to this case.

"'*Further Observations on Blasting the white Limestone of Antrim Coast, by William Bald, Civil Engineer, F.R.I.A.*'

"These further observations are directed more especially to the principle assumed by Mr. Bald in his previous communication, that the force of the explosion of gunpowder is as the cube of the length of the line of least resistance. This is the law which Vauban and Belidor have been led to assume as the result of their investigations, and Mr. Bald proceeds to show that his experiments confirm it. It appears from the experiments there detailed, that 1·9 oz. was required for the smaller blocks, and 2 oz. for the larger, per cubic yard. Knowing then the quantity of gunpowder used, and the solid contents of the blocks, we have only to extract the cube root of the cubical contents of their respective masses. Taking then the length of the line of least resistance in each of these cubes to be equal to the distance from the centre to the nearest point on the surface, we know from the preceding calculation the lengths of these lines, and it appears that these experiments confirm the law of the explosive power of gunpowder, being as the cube of the line of least resistance.

"The paper concludes with remarks on the purposes for which this limestone is adapted, and on the ravages to which all calcareous rocks are subject from the Pholas Dactylus, and is illustrated by drawings of the forms, fissure of the limestone, and of the beautifully radiated and fluted shell of the Pholas. From the curves traced by nature in this shell, the engineer may learn the best shape to be given to the slopes of breakwaters and harbours exposed to the run of the ocean.

"'*On Warming and Ventilating; by James Horne, F.R.S., A. Inst. C.E.*'

"In this paper the author describes a method of warming and ventilating, on the principle of spontaneous ventilation, by means of an iron stove, care being taken that the *quality* of the air is not affected by the iron plates exceeding a certain temperature; and mentions a successful attempt to warm and ventilate a chapel on the same plan.

"Mr. Horne gives also an account of a method which he had adopted to ventilate an extensive drift or level, by forcing in air. The machine, a drawing of which, with all the details and dimensions, is annexed, consists of an upper cylinder inverted, and working in a lower cylinder nearly full of water. An attempt was at first made to ventilate by drawing out the foul air; this, however, did not succeed. The level is 7 feet high, and 4 feet 6 inches wide, and driven a mile before a rise into an upper level; the rise was then put up 400 feet in height; both level and rise were ventilated successfully by this apparatus. The diameter of the ventilating pipe was 5 inches, its length a mile. This showed most satisfactorily that ventilation could be effected by forcing in air through a great length of pipe.

"Some conversation took place on the power expended in producing this ventilation, and on the friction of air forced through pipes; and reference was made to several cases which seemed to show that air could not be forced with effect through a great length of pipe, as for the purpose of blowing blast furnaces, whereas some experiments seemed to show that air could be forced through small pipes of 50, 100, or 150, in length, with the same velocity under a given pressure.

"Mr. G. H. Palmer stated, that if 100 cubic feet of air could be forced through a small hole under a pressure of *one* inch of water in a given time, only 25 cubic feet would be delivered under the same pressure through a pipe 1000 feet in length in the same time.

"Mr. Hawkins stated, that in the old Thames Tunnel a two-inch pipe had been found quite insufficient for ventilation at a distance of 400 feet, but that a three-inch from the same bellows, and under the same pressure, had been quite sufficient. In the former case it was suggested that the friction of the pipe was nearly the same as the pressure in the bellows, so that the air was simply condensed.

"Several other instances and experiments were quoted, and it appears that we must often consider whether the condensation has had time to take effect. The air may be condensed rapidly and none forced out, but if the operation takes place slowly, the condensation will have time to take effect.

"June 6, 1837.—The President in the Chair.

"The subject of forcing air through pipes and of ventilation being resumed, Mr. Cottam stated a case in which a circular blowing machine, having a straight pipe 10 feet in length, and 6 inches in diameter, was sufficient to supply three furnaces, but that a single elbow rendered it incapable of supplying one.

"Mr. Oldham, of the Bank of England, stated, that in all the attempts which he had made to effect any purpose, he always endeavoured to imitate nature. Now nature supplies a large quantity of air slowly heated. He had consequently established a stove with a very large heating surface, and a pump capable of delivering fifty cubic feet per stroke. To get rid of the foul air, he made large openings in the roof, and took care that there should be an abundant supply of air properly heated. The air is brought in at a temperature of 180° F.; thus there is a rapid change of air; and a summer heat is obtained without any sense of oppression. The success which had attended this system during two frightful seasons of typhus and cholera in Dublin, would be attested by many medical men; in the middle of winter he kept the doors and windows open, and threw in abundance of warm air.

"'*On the Methods of Illuminating Lighthouses, and on a Reciprocating Light; by Captain Smith, of the Madras Engineers, F.R.S., A.Inst.C.E.*

"In this paper, Captain Smith details the two different systems of fixed and revolving lights, which are generally adopted, and the objections to which each is liable. In the fixed light, the effect produced is precisely proportioned to the means employed, and none of the light is lost, since none of the reflectors are pointed inland; but in a revolving light, provided the revolution continues complete, part of the light is expended to no purpose. The revolving light is however necessary in many cases, since it is only by a series of flashes and eclipses succeeding in a determined order, that the particular lights on a thickly-studded coast can be distinguished from each other.

"As a means of obviating the objections to which each is liable, Captain Smith proposes, in places where lighthouses are not numerous, to stop the revolution of the apparatus after a certain portion of the circumference has been traversed, and then to reverse the motion so as to cause the light to reciprocate. The action of the reflectors is thus confined to the sea-side only. By this means, a light may be obtained at five-eighths of the expense usually incurred.

"The paper is accompanied by a diagram descriptive of the mechanical contrivance for obtaining this alternating motion.

"June 13, 1837.—The President in the Chair.

"Mr. Oldham resumed the account of his system of warming and ventilating, and exhibited a model of his stove for heating the air. He was convinced that the expedient of forcing the air by mechanical means must be resorted to. He had raised the temperature of a room 24° F. in one hour; by a spontaneous ventilation he could never obtain a temperature of more than 100° F., but by pumping in the warm air he readily obtained a temperature of 150° F., or 180° F.

"Mr. Horne called the attention of the Institution to a lamp which he thought would be peculiarly applicable to lighthouses, or wherever an intense light is required. The usual burners are an inch in diameter; now he had succeeded in producing a clear white light by a burner of half an inch in diameter. The excellence of the light is due to the complete combustion obtained by making the area of the external equal to the area of the internal apertures. The air thus passes directly to the burner; there is a perfect uniformity of draught, the rapidity of which may be regulated by the height at which the burner is above the bottom of the glass, or chimney. The draught of air being thus supplied with perfect equality to both sides of the wick, a flat and steady flame of two inches in height is obtained, and the force of the draught is sufficient to prevent the flame from touching the edge of the burner, so that the edge is always clean and fit for use.

"'*A series of Experiments on the Elastic Weight and Strength of Cast Iron Beams; by Francis Bramah, M. Inst. C.E.*'

"This very extensive series of experiments had been undertaken several years ago, with the view of verifying the truth of the theory of Bernouilli, Young, and Tredgold, with respect to the equality of the forces of extension and compression in cast iron within the elastic limit. The experiments are accompanied with a paper fully explaining the method in which they were conducted, and with a drawing of the proving machine.

"'*A practical Method of forming the Stones of an Elliptic Arch; by William Bald, Civil Engineer, F.R.S.E.; M.R.I.A.*'

"In presenting this paper to the Institution, the author has no object in view but to leave a record of the proceedings of an operation successfully carried into execution more than seventeen years ago. This consists in the application of the well-known property of the elliptic, 'that the lines from the foci make equal angles with the tangent at any point.' The moulds are thus traced out by drawing a few straight lines.

"This plan was adopted in the construction of a bridge over the Owen-More river, in the west of Ireland; and a model of the two courses of the cutwaters of this bridge was presented to the Institution. In these courses the stones are cut so as to break joint with each other, and the blocks are connected together into one course after the manner so ingeniously devised in the construction of the Edystone.

"The meeting of the Institution was then adjourned to the second Tuesday in January, 1838."

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS, No. 2.

BETHLEHEM HOSPITAL.

The tone of my introductory remarks appeared, no doubt, to more than one reader, to partake so much of the Bedlam vein, that they may probably suspect my *habitat* to be not very far distant from the obelisk in Blackfriar's-road. This short flight brings me at once to my present subject, which is no other than the very edifice where, in the opinion, perhaps, of more than one, I am well qualified for occupying an apartment.

And what do I purpose to say of it? Am I going to expatiate on its "front of extraordinary grandeur and beauty"—its "beautiful Grecian portico?" Hardly; unless I am desirous of proving myself to be quite as mad as any of its inmates. Rather should I say that it is precisely the kind of building to captivate the ignorant, and to obtain extravagantly fulsome compliments from ignoramus criticism; for there is plenty of it, and plenty of windows, and is moreover bedizened out with a portico in the true *soi-disant* Grecian fashion; that is to say, it exhibits a bald, common-place copy of columns with Ionic capitals, without a particle

of taste or feeling either Ionic or Athenian, or for the antique at all, in any other respect. Not only is it absolutely crowded with windows, in such manner as to present a most offensive antithesis to all classical precedent, but it is so awkwardly stuck on against the building, that instead of its entablature being continued along the whole of what constitutes the central division of the design, there are three small windows on each side, upon that line. One very injurious consequence of this is, that the portico looks depressed in comparison with the rest, the architrave being below the upper range of windows; so that in addition to having the air of being merely stuck on to the part behind it, this portico looks as if it had been borrowed or stolen from some lower structure. Yet what, it will be asked, was the architect to do? Had he carried up his columns, they must have been proportionably enlarged; which done, other alterations would have become necessary. Or was he, out of compliment to the portico, to omit all the upper windows throughout the whole extent of front?—since to have omitted them in the centre alone would have been of no avail upon the whole, but rather have tended to throw that part even still more out of keeping with all the rest than it is at present. To extricate us from these very perplexing questions, another presents itself, which in this instance is dictated equally by common sense and good taste—namely, what occasion could there possibly be for a portico at all to a building intended for such purposes as Bethlehem Hospital?—where, besides being offensively solecistical, considered in regard to design alone, it is an appendage partaking of ostentation, where ostentation partakes in its turn of hard-hearted mockery of the intense wretchedness within those walls.

If, indeed, it was the architect's intention to parody Grecian art, to bring the practice of modern portico-patching into utter contempt, and at the same time to build up a satire upon vanity, he must be allowed to have succeeded admirably; yet, as we cannot give him credit for such ingenious malice, we must per force attribute to sheer cloudiness of intellect all that he has here done. Do I say all that he has done?—let me add, all that he has left undone. For a man of any talent—any imagination, here was a golden opportunity to produce a work fraught with original expression,—one that would have legibly declared its purpose to every beholder, and would have awed while it delighted him. But—*ach! die verdammte Kunst!* as a German philosopher has it, upon every golden opportunity does it operate like a leaden incubus, smothering not imagination alone, but poor common sense into the bargain, leading us to extract nothing better than a *caput mortuum* of absurdity, seasoned with the quintessence of insipidity.

Of one thing, indeed, the architect has here given us assurance all compact, which is, that by no possibility could he at any time have become an inmate of his building, at least not in the quality of a patient: for that he was infinitely too phlegmatic. Such he must have been in no ordinary degree, where, instead of at all tasking his invention to produce what should display propriety and congruity, if nothing of originality or poetic fancy, he condescended to resort to the hackneyed expedient of tacking a crude portico to a most homespun exterior, and withal so perforated with windows in every direction, as to exhibit a direct contradiction to the style which that feature reminds us of so exceedingly *mal-à-propos*. On the score of economy, it is equally contradictory, since, if it was regard for economy which condemned all the rest to the bareness of the hole-in-the-wall system, to bring in columns merely for the nonce, amounts to a gratuitous and barefaced renunciation of any such principle. Really, there seems to be a kind of fatality attending architectural design in this respect; for as far as columns are concerned, our architects generally contrive to begin where they ought to end—that is, they determine in the first instance upon having columns, whether anything else can be made to accord with them in point of expression and richness or not; instead of endeavouring to make the most of every other part of the design, rendering it subservient to architectural quality, and working it up in such manner that columns may very properly be introduced, as a heightening touch in decoration—a *crescendo* embellishment, and a suitable climax to all besides. It is owing to a disregard of this wholesome principle in composition, that most of our new churches in the "classical style" betray an utter absence of classical taste, or rather, a taste not alone negatively unclassical, but in direct opposition to that manifested in the works professed to be followed. With such a very flagrant example of the misapplication of a portico, as Bethlehem Hospital affords, it might reasonably be thought that subsequent architects would take warning; for even did it possess the merit of being a fine specimen of the kind in itself, and in perfect keeping with the building to which it is attached, it would still be a preposterous inconsistency as the entrance to a building which serves as a receptacle for lunatics and maniacs. How infinitely more becoming would have been a portal in a simple, yet noble style, which, in that case, might have been extended to other parts, so as to have rendered this extensive line of front one consistent façade, whereas at present it exhibits a centre building, with a large *flare up* of a portico—the vulgarity of the expression must be excused for the sake of its forcibleness—placed between two sash-windowed elevations, of most ordinary physiognomy. Of the "grandeur and beauty" which others have discovered in it, we are unable to discern the slightest trace; nor do we think any one can point out any other species of it than that which arises solely from extent, and which is in no small degree counteracted by the petty and truly insignificant character of the features that are crammed into it. Had the architect at all aimed at energy in his design, he would have disposed his windows very differently, have been far more sparing of them in the front of the building, which is now quite cut up, almost drilled and reticulated by them, the proportion between the solid parts and the voids, or the apertures, approaching nearly to that between the bars and interstices of a massive grating.

Undoubtedly, as far as size alone goes, the building is calculated to make some impression upon the spectator—the entire front extending very little short of 600 feet; yet, instead of size being made to contribute to *impressiveness* and greatness, or being at all enhanced by grandeur of conception and nobleness of forms, it is for the most part nullified by a truly lackadaisical insipidity. In architecture, bigness is one thing, and greatness is another, although the public, and those who undertake to guide the public in such matters, do not appear to be aware of the slightest difference between the two, consequently fall into the same unlucky mistake for which a blundering courtier was corrected by Napoleon, who, when the other reached down a book from a shelf for him, saying, "Permettez, Sire; je suis plus grand que Votre Majesté;" sarcastically replied, "Dites donc, plus *long*." So, too, as respects the *plus long*—mere length, longitude, or elongation, the building here spoken of may be allowed to bear away the palm from most others in the metropolis; yet, independently of that qualification, it possesses no quality as a production of architecture, or as more than a piece of mason and bricklayer's work. The *ensemble* is frigidly prosaic, nor is it rendered at all less so by the appendage of a portico, which here shows itself to be nothing else than a flourish of architectural bombast and downright clap-trap. A *design* of this description might be achieved within an hour—and, I should say, an after-dinner hour, were it not that it exhibits no *verve*—not a single particle even of such fancy and imagination as a bottle of wine might infuse into one who was otherwise a torpid and frigid mortal.

Extracts from a Paper, entitled "Considerations, &c.," read before the Architectural Society, on Tuesday, Jan. 2, 1838, by THOMAS HENRY WYATT, *Esq., Vice President.*

HAVING been requested, at a very short notice, to read a Paper before the present Meeting, I have been unable to prepare one in accordance with my own wishes, or which would be likely to interest the attention of those not belonging to the architectural profession. I must therefore draw largely on your kind indulgence, and content myself with laying before you a few remarks which I had put together for the exclusive consideration of our own members. In doing this, I shall probably lay myself open to the charge of presumption for choosing a subject on which neither my age nor practice can render me an authority; still it was one that struck my fancy, and which, if properly dealt with, cannot fail to have some interest. It has also this advantage, that it is one on which no standard authority exists, and where the views of any follower, if founded upon common sense and a high principle of honour, cannot mislead. * * *

Much has already been said and written in objection to the system of competition adopted in this country—various schemes have been devised for its alteration and improvement. I have heard of none that appear to me unobjectionable; for whilst vanity and selfishness form so large a portion of the alloy of human nature, I can conceive no plan, no test of merit, that would prove satisfactory to disappointed candidates.

If I wanted confirmation of this belief, I might cite, as a case in point, the recent decision upon the designs for the parliamentary buildings, where, unless we are justified in setting aside the solemn assertions of the Commissioners (men previously of undoubted honour and truth), there is no ground for believing that interest or partiality had any foul weight. And yet, sir, whilst no decision on architectural competition (certainly within our recollection) ever received the confirmation of public opinion more unequivocally or unanimously, was there ever one that called forth more uncompromising hostility?

By some it has been proposed, that professional men, and those competitors, should alone be judges in these competitions. I will fearlessly ask, if in this case such had been the ordeal through which the designs must have passed, would their decision have been different? And if not, would the wound thus inflicted by the hands of a brother have been thought less unjust, less painful, than as coming from those birds of ill omen, in our day called Amateurs?

Much stress and much objection is applied to the influence of interest; but until you devise some means of effectually insuring secrecy, and until you change the tone of English feeling, you will find interest, which I call *the zeal and energy of friends*, carry a powerful weight.

It is not to the fair and *avowed* exercise of friendship or patronage that

I object; but it is against that unblushing abuse of it, under the garb of "fair play to all parties" (which, I regret to say, has lately been so conspicuous), that I would raise my voice. Much do I wish that some uniformity of proceeding amongst the respectable members of our profession could be laid down as a rule of conduct, and it appears to me a point on which the powers and utility of the two architectural societies might well be brought to bear. Had some acknowledged "*Esprit du corps*" been understood and acted upon, should we have had architects of respectability accepting invitations for plans, &c., addressed to "Builders, Surveyors, and Architects!" Such, sir, was the prelude to more than one advertisement emanating from those most liberal *Guardians* of their own pockets, rather than of the standing and consideration due to an enlightened and useful profession. It is somewhere said, that the repetition of injustice induces the belief on the part of the injured, that their oppressors have the *privilege* of maltreating them. It would really seem as though architects had arrived at this point of submissivenes with respect to competition committees, there being no affront, however barefaced, which they do not seem to have made up their minds to bear.

These repeated acts of injustice, and public affronts to a whole profession, can have only the effect of lowering the members of that profession in public opinion, as manifesting their own disunion and submissiveness. It would be well if, in self-defence, some higher ground could be taken by the profession; but I believe the remedy must emanate from ourselves; for I have no great faith in the honourable and liberal feelings of committees, where men do not hesitate as a body, to commit acts which, individually and separately, few would have courage to acknowledge.

I almost wonder that architects can be found willing to submit plans in the face of such acts of favouritism as have been recently perpetrated. In the cases of public competition recently advertised for at Reading, Leicester, Ashby-de-la-Zouch, and Oxford, the prize has, I am informed, in each case been awarded to *a local architect!* It will not, I imagine, be argued, that IN EACH of these cases the talent of the native practitioner must have shone resplendent over the 20 or 30 other competitors (in some of these cases consisting of men of acknowledged talent); or that such abilities could have lain, as it were, "hid under a bushel," only to be developed by contrast, and the sharpness of a canvass! If, sir, the successful candidates in these instances have the superiority of talent which their selection would imply, it cannot have been the growth of a day;

> "Such flowers mature by parts; must take their time
> To stem—to leaf—to bud—to blow!"

and cannot surely have been unknown to, or unappreciated by, those determined to ensure them a triumph, at the expense of their fellow labourers. How much more manly and just would it be, in the first instance, to avow their belief in the ability of their *protegé*, and their determination to intrust him with their employment! Committees might then openly (as they *now* do privately) make him acquainted with their wants and wishes, and thus secure more perfect plans, without the wasting the time of those to whom time is income. If, after such results, the beginner, in the fulness of hope, throws for such prizes, I would have him prepare his mind for the "influence of interest," if he would avoid disappointment and annoyance.

I would, however, have him fight with every honourable and legitimate weapon which his adversaries can use; but a decision having once been made, I would have him avoid, as he values the high opinion of his profession, and of those *whose judgment he seeks to turn*, all attempts to prejudice a rival, or set aside such decision, unless, indeed, there are grounds sufficiently strong to justify such a course. If successful, there should be such a mixture of modesty and gratitude in our demeanour as will very soon beat down the prejudice and ill-humour of those who had supported other and defeated candidates.

No employment requires such care as that obtained by competition under boards or committees. Too much consideration cannot be given to every reply—too much care and detail to estimates—to contract drawings and specifications—for, surely enough, there will be found on every committee one Joseph Hume, a single false step, a glimpse of extras, however distant, puts you in his power, and you are not likely to be dealt with less vigilantly, less mercilessly, than is the unfortunate propounder of Ways and Means in the House of Commons by this peerless economist.

In the different meetings which previous to commencing and during the progress of the works you will be expected to attend, your opinions on many points will naturally be required: these should be given with much consideration, but with firmness; for, in endeavouring to suit our opinions to the conflicting ones you will hear urged, I believe that the invariable result is, that you *satisfy none*, and impress several with the idea, that having no decided opinion of your own, there can be neither science nor experience on which to found one.

Your sketches once approved, contract drawings and specifications are generally wanted, as hurriedly as the committees have been tardy in making up their minds to build. But in these the architect should never consent to be hurried improperly. Time and consideration in preparing them are the only guarantees against oversights; and when the results of these show themselves in bad construction or unexpected changes, the committee will have forgotten the haste, and *you alone* will be the scape-grace. These drawings cannot be too minute, or the specification too much detailed; and I would strongly urge the advantage of furnishing all the drawings before the contract is entered into, instead of promising detail drawings during the progress of the work, as I hear is too frequently done. It almost invariably produces dissatisfaction on the part of the contractor, and, in my opinion, carries with it a certain degree of injustice on the part of the architect, who must either imagine that the builder can divine his *exact ideas of decoration*, or he must consent to his employer being charged, perhaps, an exorbitant sum to cover the future flights of his fancy.

On the subject of furnishing the builders with the exact quantity of materials, &c., from which they are to estimate, some difference of opinion seems to exist in our profession.—Some think that the architect should have nothing to do with this part of the business, and that in doing so, he involves himself in a dangerous and unnecessary responsibility. Others (of whom I am one), argue that the architect should be aware from what quantities the estimate is made, and that the way of ensuring the fairest competition is to furnish all with the same data. In London it has become so general a rule with the large builders, that they will only furnish tenders on their own terms; and they will not incur an expense which is not to be repaid by the employer. Neither will they run the risk of oversights or inaccuracy from employing only one party to take out the quantities; but in cases where the architect does not insist upon appointing one surveyor on his part, they appoint two; nor do I see that any valid objection can be urged against this caution on their part. On whom can the cost of making this accurate and detailed estimate fall so justly, as on the party for whose use it has been calculated! It is one that may very fairly be considered as contingent upon the benefits of competition; for it would be rather too much to expect builders to incur the risk and odium of cutting each other's throats (and frequently their own) with the additional privilege of incurring a heavy expense for this chance. The architect may fairly claim to appoint one party;—the employer should pay the expense, and the advantages of having a *mutually acknowledged* measurement of quantities to refer to in case of dispute or misunderstanding, must, I think, be fully equal to its cost, and can entail no responsibility on the architect with which he may not fairly be charged.

On the principle of believing "every man a rogue till you find him honest," prepare your contract drawings as though you anticipated quibbles and trickery of every kind, and in every trade. If the builder starts with the idea of *scamping*, this will soon pull him up; if he intends to complete his work honestly and conscientiously, he will merely be spared the trouble of thinking what would be necessary.

I will suppose that the site, the aspect, the foundations, and the materials of which the building is to be erected, have been considered before the first sketches were made—but I will not suppose that any decision on these points has been so perfect as to be incapable of improvement. The increased intercourse with the locality which the fact of his employment will necessarily cause the architect before his building is commenced, will afford time and opportunity for each observation and inquiry on these heads. Too much care cannot be given to the selection and testing of materials; this should be a primary inquiry—for I hold, that design and construction should be made applicable to the materials at your command, and not, as I have known, expensive and uncharacteristic materials forced into a design. The proper aspect for a building is so dependant upon circumstances, and the fancies of individuals, that it would be difficult to lay down any definite rule. Aspect should be more considered than prospect, and these relatively studied when the weather is unfavourable as well as fine, in order that the judgment may be exercised towards every circumstance and defect.

In these decisions, our employers generally require, and indeed they have a right to do so, the indulgence of their own whims; and the ingenuity of the architect (who, to design successfully, should have studied and experienced the wants and habits of the different classes for whom he may be employed) should consist in making the most of these prejudices, rather than in endeavouring to force his own ideas on those who will, at best, give him but a *reluctant* acquiescence.

This, however, should not include a frank and honest showing of that which we conceive to be best adapted to the objects in view.

The contracts once signed, and the works commenced, you are brought into connexion with parties who have your credit and comfort much in their power (dependant though, as I have invariably found it, on your conduct and manner to them). Between unnecessary hauteur or severity and a culpable laxity, there is a happy medium which should be acted upon. There should be a cordiality and confidence existing between the architect and builder; whilst, on the one hand, I would vigorously protect my employer from any thing approaching to fraud or illiberality, so would I not hesitate to assist the builder, to listen to his views or proposals, and where I conscientiously believed that his suggestions could in no way prejudice my employer, though they might benefit him, I would gladly act upon them; with common courtesy, common confidence, and such concessions only as can be honourably and properly made, I believe architects might be very free from annoyance during the progress of the works, and from odium after their completion. * * *

The difference between London and country practice is greater than would at first be imagined. In the former, you are almost invariably hampered by acts and by-laws, many of the most absurb and unintelligible nature; difficulties are raised by parties, frequently with no other object than annoyance and litigation. You are subjected to the inconsistencies of the Building Act, or to the whims of Paving Boards and Sewer Commissioners; and though last, not least, your works are generally tested by severer rules of criticism, and less partial judges, than in the country. There, you have little more to consider than that your building shall be no injury or annoyance to those on whose property it abuts, and that it shall not encroach on public or private conveniency.

I may here be allowed to say a few words on the subject of *landscape gardening*, a pursuit so enjoyable in itself, and so intimately bound up with our operations, that I am almost inclined to lay exclusive claim to it for the architect; at any rate, I must contend that those who have felt and studied the peculiarities of certain scenery, and have designed buildings to harmo-

nize and group with those features, must be as competent to work out a general "tout-ensemble," as the fashionable landscape gardener, who in his morning ramble levels wood and hill as with a magic wand, and who will, perhaps, not condescend to consider the character of the house as influencing his decisions. "The picturesque eye is not limited to nature, but ranges through the limits of art—the picture, the statue, and the garden may be equally the objects of its attention." It does not therefore follow (as some imagine), that from the architect's intercourse with works where proportion and order and regularity are essentials, our ideas on picturesque effect must necessarily be warped; taste is intuitive, and may be as judiciously and picturesquely applied by the architect in working out and bringing together the beauties of nature in the park or garden, as in proportioning and adjusting those of art in the portico or tower. I know no education that will give taste, where none is inherent. Neither rule nor axiom will carry you through her varied bearings; and I cannot help thinking, that he who has a natural love for scenery, who has studied the various effects of light and shade, of distances and of contrasts, and who has, to a sufficient extent, the power of embodying in his own mind the effect of contemplated alterations, and, in the mental eye, to judge accurately of the results, is as well qualified to *garden a landscape* as a Repton or a Gilpin. I have made it a point, in cases where I have been employed in the country, to be indulged with the general arrangement of the adjoining grounds; considering it so intimately connected with the spirit of the design, and so gratifying an occupation in itself. The architect need not be deterred by the want of *practical knowledge* as to the species or growth of trees, &c.; it seldom happens that the head gardener of any establishment where such occupation would probably be required, is not qualified to render you every assistance in practically working out your ideas and intentions. If we bear in mind this undoubted fact, that "*simplicity* and variety are equally sources of the sublime as of the beautiful," we shall seldom err.

The fault of some scenes that have passed through the ordeal of landscape gardening is, that there remains either an affected simplicity, or that nature has in the generosity of her doctor been sadly surfeited. Hill and dale, wood, water, rock, and heath are unceremoniously jumbled together, without thought of harmony or consistency;—

> "If thy skill should fail to people well
> Thy landscape, leave it desert,"

was the advice of one considered a good authority on these matters; it certainly is a safe one. * * * *

ROYAL INSTITUTION, EDINBURGH.

Sir,—I should feel obliged to any of your correspondents who could furnish some information of this building, since it appears to have undergone very material alteration since its first erection, amounting almost to an entire metamorphosis, and one that is a decided improvement upon the original design. I say 'appears,' because I have never heard of such alteration having been made, neither is there a syllable relative to it, in the very work which gives a view of the building, in what must naturally be concluded to be its present and actual state; namely, the recent publication entitled 'Caledonia,' edited by Dr. Beattie. It is strange enough that there should be no description whatever of the building; but it is still more strange that the Doctor should have been, or else have chosen to appear ignorant of a mere matter of fact, and certainly a rather important one. Besides which, the alteration itself must be one of very recent date—subsequent to the publication of 'Jones's Views of Edinburgh,' because the representation there given of the Royal Institution, exhibits a design altogether different. There, the portico beneath the pediment consists merely of a single range of eight Grecian Doric columns, advanced one inter-column before the general front; but this part is now, it would seem, greatly extended, as regards its projection, by the addition of another range of columns, and at such distance as to give three columns, and as many inter-columns, at each end or return of the portico. Neither is the change confined to this alone, the metopes of the frieze being ornamented with wreaths, and the tympanum of the pediment with a rich arabasque foliage of Grecian design, filling its entire space; besides which, the podium, against which the pediment abuts, has received some sculptured ornaments, and columns supporting lesser pediments have been added to the lateral façades, to say nothing of other variations. Notwithstanding all this, the Doctor takes not the slightest notice of there having been any change made at all; which odd silence, even were it a perfect matter of indifference to the rest of the world, is anything but complimentary to the 'gude folk of auld Reekie!' Yet almost any other writer would have deemed it incumbent upon him to have given some account of such change, and informed us both when it took place, who promoted it, and who was the architect employed to carry it into effect, and finish up Mr. Playfair's design as it is at present. Or, are we to suppose, that the Doctor was not himself aware that the building had been any way altered, perhaps never saw the view given of it in his work until after it was published? In the latter conjecture there is nothing particularly monstrous, because to write such letter-press as he has furnished, there was no occasion for him to make himself acquainted with the plates beforehand; nay, it is very possible, that he considers them to be the mere filling-up stuff of the work—the childish garnish with which the publisher has thought fit to bedizen, and almost overlay the *literary* portion of it. For aught I can tell, Dr. Beattie may be a 'Beatus Doctor' in every other respect, but he deserves to be a *beaten* one for his scurvy cavalier-treatment of architect and architecture, as being altogether undeserving of notice. Some one of your Edinburgh readers will, I trust, now supply the information the Doctor has forgotten, and for which I now most humbly petition.

P. DRYWATER.

JOYCE'S WARMING APPARATUS.

A contrivance for warming apartments, &c., has been some time past on exhibition at the Jerusalem Coffee-House; this consists in external figure (no explanation being afforded of the nature of its contents) of a copper cylinder about eighteen or twenty-four inches high, and six inches diameter, with a small orifice at the top, through which the vapours given off by combustion passes. It would be premature to offer opinions until the nature of the invention is more fully displayed; but it is asserted by the inventor, that a cylinder of the dimensions above quoted will warm a room of twelve feet square and ten feet high, up to sixty or seventy degrees, an assertion we scarcely think it possible he can confirm: the apparatus, when we saw it, was not hotter than two hundred and twelve degrees, and how it is possible a heating surface, about three feet super., not greater than a common tea urn, can heat up a room of the above dimensions, when it requires a surface of iron pipes filled with hot water of ten times the surface to produce the same effects, is to us inexplicable, the mere surface of one moderate size window, twenty feet super., cooled down by the external air to perhaps four or five degrees below the freezing point, is six to eight times the surface of the warming apparatus at two hundred and twelve degrees; it would be therefore impossible, by the application of this means, to keep up the heat of the window to anything like the temperature of sixty degrees. We are afraid there must be some mistake in the inventor's calculations, and unless the heat can be increased in intensity, or the surface enlarged, or both, it will be found useless for the purposes to which it is proposed to apply it; and if the intensity of the heated surface, or the air escaping from the funnel, should be made to exceed two hundred and twelve degrees, the apparatus will be subject to all the objections attending hot air and German stoves, which, by their high temperature, destroy the oxygen of the atmosphere, and render the air exceedingly noxious and poisonous.

INCRUSTATION OF BOILERS.

Sir,—In your Journal for December, 1837, under "Steam Navigation," the attention of your readers has been called to the observations of Dr. Lardner, at Hull, &c., on the incrustation of Marine Boilers.

It is stated that "copper, having a detergent power, and not being a recipient of deposit, becomes an effectual remedy when substituted for iron, the incrustation of which causes a great loss of fuel."

I beg to remark, that as the deposits are separated simply by the operation of boiling, and in quantity proportionate to the concentration of the sea-water, a copper boiler, under the same circumstances, would be incrusted equally with an iron boiler, while the chances of injury to the former would be increased, from its being a better conductor of heat, and less able to withstand its effects than the latter.

These facts are borne out by the condition of Marine Copper Boilers now in use, as well as by those which were laid aside some time since after service at sea, where considerable injury had been sustained in the parts most exposed to the fire from the effects of incrustation, specimens of which were preserved by many as curiosities. Your's, &c.

Woolwich, *January* 19, 1838. NAUTICUS.

BRICK AND CEMENT BEAMS.

Sir,—We observed in the December number of your interesting work, (page 45) an article respecting the Brick Beam erected on our premises at Nine Elms. It is, generally speaking, a correct representation; a little error, however, with respect to the iron hooping laid longitudinally in the beam, may mislead, which we therefore mention, and at the same time beg to enclose the accompanying sketches of its elevation, &c.*

Your correspondent A. C. E. truly observes, that only five iron-hoops are visible, whereas, we believe, there are not less than ten or a dozen laid in the *work*. The fact is, that all the hoops were inadvertently cut off parallel with the face at the time of its erection, and the five ends now projecting are merely pieces introduced to show that iron was used.

Considerable interest has been expressed by scientific persons, as to what further weight the beam will carry: an opportunity will offer shortly to ascertain the fact. The London and Southampton Railway Company requiring that portion of our premises on which it is erected, we have fixed Wednesday, 14th February, at 12 o'clock, for the time when we purpose to load it until it breaks down, and when any of your correspondents, who may be so disposed, may witness the operation. Sir, your obedient servants,

January 20, 1838. CHARLES FRANCIS & SONS.

RAILWAY CHAIR.

Sir,—In looking over the last number of your Journal, I observed a description of a new chair and mode of fastening by Mr. Curtis. I beg to state, that the chair he describes, viz., with the place for the key rounded in the middle, has been used nearly two years for the strong rails which have lately been laid to replace the old ones on the Liverpool and Manchester Railway, and the manner of keying he describes, was proposed by me about nine months ago, to remedy the defects of the wood key introduced by Mr. Locke; but I could not procure its adoption, although its advantage over the common kind of wood key is pretty evident.

I do not wish it to be understood that I consider Mr. Curtis to have gained the idea from me. I merely state a fact, to show that he has not been the first to bring the method forward. Yours, &c.

Manchester, *Jan.* 4, 1837. GEORGE SCOTT.

* We have deferred publishing the sketch until next month, when we shall be able to show them to more advantage, accompanied with our observations on the fracture of the beam that is to be broken on the 14th instant.—Editor.

ON WARMING BUILDINGS BY HOT WATER.

Sir,—In the last Number of your Journal you published a review of a work recently written by me "On Warming Buildings by Hot Water, &c." I am gratified by the favourable opinion you have expressed of the general character of this work, and I feel obliged by the fair and candid tone of your remarks on those parts of the treatise which you consider are liable to objections. Those remarks appear evidently to have been made with the desire of forwarding the progress of a useful invention, the principles of which are but imperfectly understood; and I am therefore induced to make a few observations on those remarks, which I should not otherwise have done.

The objections which you urge against the work in question are, that the deductions are not sufficiently based on practical investigations, and that they rest too much on theory. This, however, I shall show is not the case; were it so, your remarks would be eminently just. One passage in the book has apparently escaped your observation, which, had it been observed, might probably have altered your opinion as to its theoretical character. At page 56 it is stated—"The correctness of the theories advanced in this treatise, which are of a practical character, and admit of verification, have been tested, more or less extensively, by actual experiment, and do not, therefore, rest merely on hypothetical reasoning." The mode which you have pointed out for experimentally determining the proper proportions of the apparatus for different buildings, is, as nearly as circumstances would permit, the method which I adopted, in the first instance, for this purpose. By these means I obtained the practical rule given, Art. 159, for ascertaining the quantity of heated surface required in any particular building, by merely dividing the cubic measurement of the building by certain numbers there given. This rule has since formed the basis of calculation, in many cases where the apparatus has been erected in a most successful manner, and its general accuracy has thereby been ascertained. But it is evident that such a method can only give an average result, however extensive and varied the experiments may be. Not only would the same apparatus produce very different effects in different buildings, but the same apparatus would produce different effects in the same building, with every change of temperature, external as well as internal. For an apparatus, for instance, which, at its maximum intensity, would raise the temperature of a building 30 deg. in cold weather, would not raise the temperature 30 deg. in warm weather; and it would be impossible, by any such mode of experimenting, to ascertain either the law of its variation, or even the cause of it.

But the method which I adopted of calculating from philosophical data of acknowledged accuracy, enabled me to estimate all the causes of variation of these effects, and to apply proper corrections for them in practice. By applying the laws of the theory of heat, the cause of many effects which appeared discordant in their results became obvious. I will not, however, occupy your valuable pages by describing these various results, but will confine my remarks to your objections to the experiments having been made on a small scale.

I need not adopt the axiom, that matter obeys the same laws in the *atom* as in the *mass*, and that therefore the size of the body experimented upon was unimportant. A different and a far better reason can be given for the plan which was adopted. In order to calculate the effects by the laws of specific heat, when applied to this inquiry, it was necessary to ascertain by experiment the rate of the diffusion of heat from iron and from glass. If a large heated surface had been employed in these experiments, the temperature of the surrounding air would have been instantly raised, and this would at once have altered the rate both of radiation and conduction from the heated body, and the experiments would therefore have been wholly futile. To avoid this consequence, it was necessary to employ a moderately small body; and even with all the precautions which could be adopted, the rise in the temperature of the air could not be entirely prevented; although, in the experiments in question, it was of but small amount, and therefore could easily be allowed for in the calculation. The body employed was, however, sufficiently large to obtain the most perfect accuracy, and the calculations deduced from these experiments are, I conceive, for these reasons, far more accurate than if they had been conducted on a larger scale. The rules which I was enabled to form from these experiments agree, in a majority of cases, in a very perfect manner with the practical rule already mentioned; and where a difference occurs, they distinctly show the cause of that difference. Had I not possessed a practical rule obtained by comparisons of working apparatus, I should not have felt justified in broaching the other rules deduced principally from philosophical data; but having proved their accuracy in this manner, I had no hesitation in giving them as rules which might be adopted in all cases with the most perfect safety.

Your observations respecting the great difference which occurs in the consumption of coals, in different apparatus, in the warming of buildings, are perfectly correct. But it is, I consider, equally correct, that no investigation such as that you have pointed out, would satisfactory account for this difference, except so far as the furnace might be constructed on good or bad principles. But with low pressure steam-engine furnaces, there is not so great a difference in the results. The consumption of coal can then be estimated with tolerable accuracy by its effect in producing a certain quantity of steam; and pursuing this subject in connexion with the laws of the radiation of heat from pipes under different circumstances, as exemplified by the experiments above mentioned, it at once became apparent that the consumption of coal, in a hot-water apparatus, by no means continues constant even in the same apparatus; but that it depends upon a multitude of circumstances which are continually varying, and which are very greatly different in different buildings, and with different apparatus. The table given, Art. 154, clearly points out the cause of this difference. It shows, that, independent of any difference in the construction of the furnaces, the consumption of coal depends upon the difference of temperature between the heated surface and the circumambiant air; and as this again is governed by the temperature of the external air, the quantity of glass, the form of the building, the quantity of pipe, the amount of ventilation, and many other causes, the reason of the great difference which occurs ceases to be a matter of surprise. But the mere inspection of working apparatus, and a comparison of the quantity of coal used in each, while it would plainly show the difference which occurs in this respect, could not in any manner explain the cause. An inquiry into the theory and the laws of heat, was, I think, necessary for this purpose; but whether sufficient explanation of this part of the subject is given in my work, I leave to others to decide.

I might allude to other matters connected with this subject, but I am unwilling to trespass further on your valuable columns. Enough has, perhaps, been stated, to show that the deductions contained in the work in question are not of a theoretical, but of a practical character. Experience has convinced me of their accuracy; and from a tolerably extensive acquaintance with the wants of those for whose use the work was chiefly designed, I have reason to believe it will be found useful. I shall, however, be happy to avail myself of any hints that may be given on this subject, for the purpose of making any further experiments that may be useful; for, no doubt, there is much yet to be learned before this invention can be considered to have arrived at perfection.—Your's, obediently,

London, Jan. 12, 1838. C. HOOD.

HOUSES OF PARLIAMENT.

Abstract of the Tenders delivered by Builders for the Embankment and the Terrace, and a Portion of the Foundation of the Buildings, of the Houses of Parliament.

	£.
Hugh MacIntosh . . . . To complete the coffer-dam within seven months. To finish the whole of the works within twelve months.	82,000
William Cubitt . . . . To complete the coffer-dam within eight months. To finish the whole of the works within fifteen months.	77,500
George Munday . . . . To complete the coffer dam within eight months. To finish the whole of the works within two years.	93,800
Henry and John Lee . . . . To complete the coffer dam within eight months. To finish the whole of the works within sixteen months.	74,373
George Baker and Son . . . . To complete the coffer-dam within nine months. To finish the whole of the works within eighteen months.	74,450
Grissel and Peto . . . . To complete the coffer-dam within ten months. To finish the whole of the works within twenty months.	83,900

The Tender of Messrs. Henry and John Lee being the lowest, was accepted.

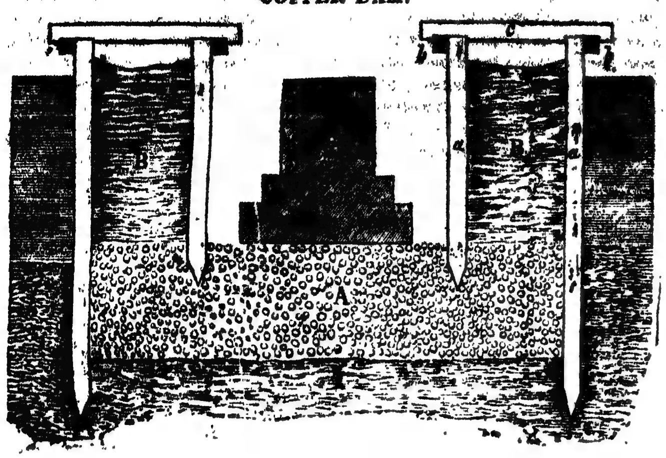
Estimate, made in part by Messrs. Walker and Burgess, engineers, and in part by Mr. Barry, the architect, for the embankment to the river, with steps, coffer-dam, &c., examined and adopted by the Surveyors of the Office of Woods and Works, and contained in the Report made by the Commissioners of Woods and Works, and laid on the table of the House of Commons		44,000
The Tender of Messrs. Lee, for the embankment and the terrace, and a portion of the foundation of the buildings of the Houses of Parliament	£74,373	
Deduct the amount agreed to be allowed by the Contractors for the materials of the dam, after it has served its purpose	7,000	
	£67,373	

N.B.—The works included in the above Estimate of Messrs. Lee were proportioned by Mr. Barry in the following manner:—

Cost of the embankment wall, with the steps, coffer dam, &c., included in the estimated sum of £44,000	£42,465
Cost of further works for the foundations, considered as part of Mr. Barry's general estimate for the building	24,908
	£67,373

The Parisian Casinos.—Musical casinos are now all the rage at Paris These music halls are daily opening one after the other, and surpass each other in architectural splendour, and in the profusion of lights and looking-glasses. The *National* of Friday gives a description of the Casino Paganini. It is more rich in its artistical embellishments than its predecessors of the Rue St. Vivienne and St. Honore. Nothing more tasteful nor more dazzling, says the report, can be imagined.

COFFER DAM.



Cross Section of a Coffer Dam, a la Treussart.

a a exterior and interior sheet piling to confine the puddling *B*; *b* waling to connect the sheet piles; *c* cross-ties notched on to the waling; *A* bed of *beton** to receive the masonry, *C*.

In a recent publication on mortar by General Treussart, of the French Corps of Engineers, the following method of securing a firm bed for foundations, in any depth of water, is proposed by the author. The area on which the structure is to rest, is first enclosed by strong sheeting piles, (as shown in the above figure,) driven sufficiently deep to take a firm hold of the soil. The bottom, within this area, is next scooped out to a depth of 6 feet, and the soil removed is replaced by a mass of beton of the same thickness. While the mass of beton is still green, a second row of sheeting piles is driven into it, about 6 inches, leaving an interval of 5 feet between it and the first row. This interval is then filled by a compact puddling, care being previously taken to secure the rows of sheeting piles from yielding laterally. A water-tight dam is thus formed, and the water is pumped from the enclosed area. If, from the permeable nature of the soil at the bottom, it is feared that the pressure of the exterior water, on the under side of the mass of beton, might throw it up, then it would be necessary to lay a provisional weight on this mass, before the water is pumped out; this weight being gradually removed as the structure advances.

The immersion of beton, for foundations in water, requires great care. The best plan seems to be, to use a bucket with four sides, the top being wider than the bottom; it is provided with an ordinary handle, to which a small rope is attached, for the purpose of raising and lowering it in the water. A cord is attached to the bottom of the bucket, to upset it and throw out its contents. The beton broken into blocks of about half a cubic foot, is placed in the bucket, lowered near the spot it is to occupy, and is thrown out. By this means, it is deposited in the mass in a compact state, which is essential to the firmness of the mass; for, were the beton thrown into the water at the surface, the greater part of the lime would be separated from the other elements before it reached the bottom.

To prevent voids in the different layers, each one should be firmly pressed by a ram, whilst the beton is still green, and a fresh layer must not be laid until the other has partially set.

Another precaution is also necessary to form a perfect union between the layers. Whatever pains may be taken in lowering the beton, some of the lime will wash, and remain suspended in the water; this will, finally, settle into a thin cream on the surface of the layer, and would prevent a union between it and the succeeding one if not removed. To effect this, when there is a current of water, two holes may be made in the coffer-work just below the surface of the water, to form, when left open, a current through the enclosed area. By agitating the water within the area, the lime held in suspension will be gradually carried off through the holes by the current. Or if this plan cannot be adopted, the lime, after it has settled on the surface of the layer, may be carefully swept into a corner by means of a broom, and be taken out by a scoop.

Where the area, occupied by a structure, is very considerable, and the depth of water great, the methods which have thus far been explained cannot be used. In such cases, a solid bed is made for the structure, by forming an artificial island of loose heavy blocks of stone, which are spread over the area, and receive a batter of from one perpendicular to one base, to one perpendicular and six base, according to the exposure of the bed to the effects of waves. This bed is raised several feet above the surface of the water, according to the nature of the structure, and the foundation is commenced upon it.

It is important to observe, that, where such heavy masses are laid upon an untried soil, the structure should not be commenced before the bed appears entirely to have settled, nor then, if there be any danger of further settling taking place from the additional weight of the structure. Should any doubts arise on this point, the bed should be loaded with a provisional weight, somewhat greater than that of the contemplated structure, and this weight may be gradually removed, if composed of other materials than those required for the structure, as the work progresses.

To give perfect security to the foundations in running water, the soil around the bed must be protected to some extent from the action of the current. The most ordinary method of effecting this, is to form what is termed an *enrockment* around the bed, by throwing in loose masses of broken stone of sufficient size to resist the force of the current. This method will give all required security, where the soil is not of a shifting character, like sand and gravel. To secure a soil of this nature, it will, in some cases, be necessary to scoop out the bottom around the bed to a depth of from 3 to 6 feet, and to fill this excavated part with beton, the surface of which may be protected from the wear arising from the action of the pebbles carried over it by the current, by covering it with broad flat flagging stones.

When the bottom is composed of soft mud to any great depth, it may be protected by enclosing the area with sheeting piles, to prevent a lateral spread, and then filling in the enclosed space with fragments of loose stone. If the mud is very soft, it would be advisable, in the first place, to cover the area with a grillage, or with a layer of brushwood laid compactly, to serve as a bed for the loose stone, and thus form a more stable and solid mass.

* *Beton* is made by mixing lime as a matrix with broken stone or rubble in fragments.

IMPROVED FRENCH CABLE.

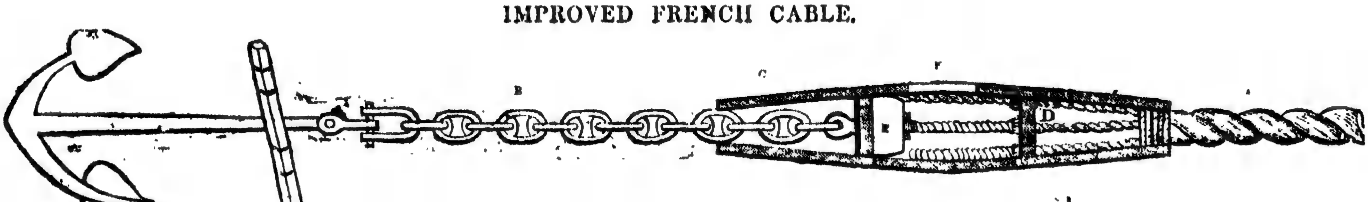


Fig. 1.

Fig. 2.

A combination of the hempen with the chain cable has been introduced into the French Navy, with some success; the chain cable is affixed to the anchor in the usual way, in length from twenty-five to forty fathoms. The object of this arrangement is to allow the chain to drag along the bottom of the sea, and prevent abrasion to the hempen cable; thus it is supposed, that greater elasticity is produced than can be obtained by a chain cable alone, and the durability of the hempen cable is ensured for a greater length of time; the cable being lighter and more manageable, is more favourably adapted for the evolutions of the ship, either in casting or weighing anchor, likewise for kedging; the advantages of lightness are evident; many other points of recommendation will present themselves to parties interested in this subject, besides that of cheapness. M. Fouque, the inventor of the method by which the chain and hempen cable are united, has designated his contrivance with characteristic French vanity, "fouquière;" this consists, as will be perceived by reference to the plate, of a kind of barrel-shaped ferrule, F, of metal, into one end of which is inserted the end of the hempen cable, A, and into the other the corresponding end of the chain, B; these are prevented from withdrawing from the ferrule by two conical glands, D E, one inserted within the strands of the cable, and the bolt of the chain passing through the other, so that when the chain is extended, the glands jamb fast within the ferrule, and are of course held the faster the greater the strain on the cable; for the purpose of fixing and disengaging the two cables, holes are left in the ferrule, by which the glands are withdrawn, which are easily loosened by drawing the ferrule forwards when upon deck.

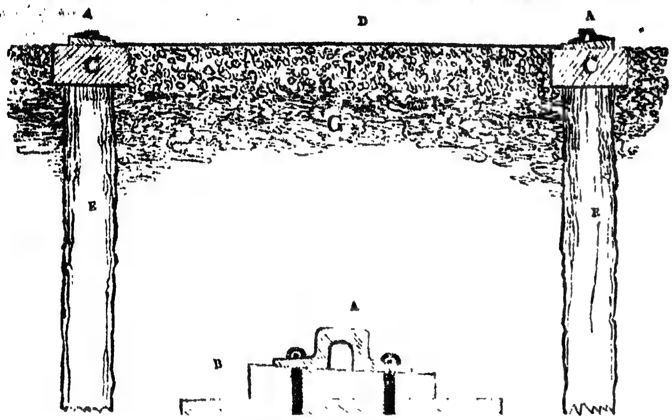
Description of Engraving—Fig. 1, is a section of the ferrule, showing the connexion of the two cables. Fig. 2, plans of the glands D and E.

A, hempen cable; B, chain cable; C, ferrule; D, E, glands; F, hole in ferrule for withdrawing the glands; the gland E for the chain, is made with a slit to pass the bolt of the chain into the centre, as the stud is fixed upon the bolt with a rivet fastening; and the gland D, is made with three or four slits or grooves, to receive the strands of the rope, which are tied in knots to prevent them slipping through.

Another method is to substitute a broad ring instead of the ferrule, and unite both chain and cable into one joint, by passing the bolt of the chain through the centre hole of the gland for the hempen cable, and then wrapping the strands and chain with a wrapper, and binding the whole with yarn in the usual way.

CONSTRUCTION OF THE GREAT WESTERN RAILWAY.

This railway, on account of its deviation from the ordinary mode of constructing railways, is watched with considerable interest by the profession and the public; it is our intention to collect as much information as we can, and lay the same before our readers; we have taken the earliest opportunity of obtaining the particulars of the method of laying the rails, which we illustrate with an engraving.



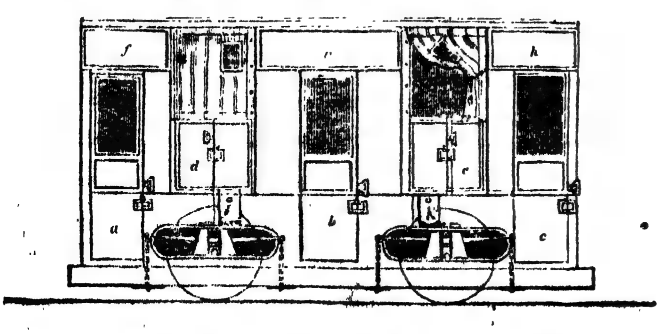
EXPLANATION OF THE ENGRAVING.

AA wrought-iron rail screwed down to sleeper; B a featheredge or wedged-shaped board of oak; CC sleepers of timber; D iron tie-bar to connect the two sleepers; EE piles eight feet long, and eight inches diameter, pointed at the lower ends; F ballasting; G embankment.

Formation of the Railway.—On the embankments, piles of beech trees Kyanized, about eight feet long and eight in diameter, are driven by a pile engine, at distances of fifteen feet apart, on each single line of rails, and so arranged that the piles of the corresponding rail are placed opposite to the intermediate distances, and not opposite to each other, thus: o o o o o upon these piles are laid longitudinal continuous sleepers of Memel timber Kyanized, thirteen or fourteen inches wide by six and a half or seven inches thick, which are firmly bedded on the ground, previously made even and well rammed; on the top of the sleepers are laid the rails, with an intermediate distance of seven feet half an inch in clear of the rails; between the rail and the sleeper is a featheredge or wedge-shaped board of oak, or hard wood, eight inches wide and one and a half inch thick on the outer edge, and one and a quarter inch thick on the inner edge, which gives the rails a slight pitch inwards, so as to make the top coincide with the levelled or conical rim of the wheels, which touches the rails with a bearing equal to the width of the top of the rails, instead of a point, as in the ordinary mode of laying them. The rails are of wrought-iron, rolled in lengths of fifteen feet, as shown in figure 2, and made hollow; the top is two inches wide, base six inches, and height one inch and three-quarters; holes are punctured in the flanges on both sides, about eighteen inches apart, to secure the rail (*without chairs*) to the sleepers, by means of screws eight inches long. To prevent the sleepers from spreading, there are, at every fifteen feet, iron ties across the railway, spiked down at each end to the sleepers; the surface of the roadway is finished with ballast in the usual manner.

BOSTON AND PROVIDENCE U. S. RAILWAY CARRIAGE,

INVENTED AND BUILT BY W. J. CURTIS, LONDON.



The carriage, of which the above is a correct drawing, was built as a pattern carriage for the above railway, in 1836; it is made upon the same principle as those of the London and Greenwich Railway Company, viz., by placing the frame below the wheels, and bringing down the centre of gravity to within a few inches of the rails. It will be perceived, upon reference to the plate, that it consists of five distinct compartments, or coaches; the floor of three is immediately upon the top of the frame, and twelve inches only from the surface of the rail, so that passengers step in and out with as much facility as from a sedan chair: the middle compartment has double seats, like a mail coach, and the two end bodies single seats, like a chariot; the two bodies over the wheels have also single seats, and may be either close bodied or open, with a leather curtain, as drawn; passengers get in, or alight, by steps similar to those of a barouch: the spaces over the low bodies may be employed for luggage, forming a commodious safe depot for that purpose; if it should be desirable to form the mail coaches upon this principle, the space over the wheels may be formed into the holds or receptacles for the mail bags, thus placing the heaviest load over the wheels; also, if desirable, the roof may be adapted for outside passengers. It is evident, from the construction of this coach, that it is absolutely safe; by no possible chance can it ever upset; it does not cost more than the railway carriages usually adopted, and by being absolutely safe, is not subject to the accidents to which the others are so exceedingly liable; and by placing juggles upon the cross-pieces of the frame, descending so low as to clear the crossings, and setting them back from the wheels, little more than the breadth of the rail on each side, in the event of the wheels leaving the rail, the frame backs in with either the one rail or the other, and thus the carriage is retained to the rail under all possible circumstances: this is a very valuable point; for when it is recollected, that almost every railway is formed, for fully one-third of its extent, upon embankments without parapets, which renders it very dangerous for an engine or carriage to be thrown off the rails upon them, this provision provides a remedy for the case, to be met by no other equally simple, cheap, and efficacious arrangement. The mode of connecting each carriage is by a solid link; to either end of the frame is affixed a spring, one of which is a buffer, the other a drag-spring, so that when the carriages are arranged in train, a buffer and drag-spring are connected by the inflexible link; by this means all the requisite elasticity is insured to the train, and the disagreeable shocks, incidental to the mode of connexion by chains, is entirely avoided.

The carriages upon the Greenwich Railway were altered by me, from the old and general plan of those upon the Liverpool, Birmingham, and other lines; this alteration is effected by simply inverting the frames, thus making a most unsafe carriage absolutely safe. I do not recommend any person to copy the form of carriages upon that line, but to adopt the form represented in the plate, which will be found in practice the most commodious of all others; the great advantage of enabling the passengers to alight at once from the carriage to the ground without the intervention of platforms is no small recommendation, but that its great security must eventually compel all the railroad companies to avail themselves of this invention, inasmuch as it will be found, not only economical to the companies in question, but the effect upon the public, by ensuring to them a degree of security unattainable by any other form of carriage, or by any other mode of conveyance, must be such as must materially enhance the value of their property, and the interests of the system of railways generally.

EXPLANATION OF PLATE.

a b c are the low bodies; *d e* the upper bodies, which may be second class carriages; *f g h* luggage holds; *i k* steps for the upper bodies.

1, Stafford Street, Bond Street. W. J. CURTIS.

Public Works of Great Britain. Edited by F. W. SIMMS, C. E. London: John Weale. 1838.

We have received, too late for a minute review, a copy of this important work, which we shall fully notice hereafter. From a general inspection of its contents, and the style of its execution, we are led to conclude that it will be found to be of great utility to the practitioner as a book of reference, and to the student in maturing his judgment. The first division of the work consists of the principal engineering works on most of the important lines of railway. The plates, which are all executed in the first style of the art, are stated to be accurate reduced copies of the original working drawings, lent for the purpose by the engineers who designed the respective works represented; and the letter-press consists of general descriptions and copies of the original specifications. A great part of this portion of the work is devoted to the London and Birmingham Railway, representing the principal works on the line, accompanied with copies of the specifications. We ought not to omit to notice the enlarged plates of that important part of the work, the cuttings and undersetting of the rock at Blisworth, in Northamptonshire. These plates, together with the whole of the working section, have been given of the full size of the original; and,

together with the specification annexed thereto, give an excellent idea of the magnitude of this undertaking. Besides the Birmingham Line of Railway, there is also a notice of the Great Western Railway, with five plates, containing copies of the working drawings of the Brent Viaduct, and of the Bridge over the Thames at Maidenhead. Then follows the Southampton, the Greenwich, the Croydon, the Thames Junction, and the Glasgow and Garnkirk Railways; also particulars and specification of rails, chairs, turn-plates, and sidings or passing-places. And, lastly, this division of the work concludes with the particulars of locomotive engines, and a specification of Mr. Stephenson's patent six-wheeled locomotive engine and tender, accompanied with a very beautifully executed engraving.

The second division contains canals, docks, lock and quay walls, both in stone and by the modern method of cast-iron piling—bridges, &c., of which, from their importance, we must defer further notice till we have had time to examine them minutely. The same observations must apply to the divisions three and four, the former being devoted to turnpike-roads, iron, steel, and gas-works; and the latter contains an historical and scientific survey and description of the Docks and Port of London.

Of this work, as a whole, it appears to us to be of a very important and valuable character; and, considered in comparison with the published price, is almost a gift to the public.

CAST-IRON BEARERS.

Extracts from a Paper on the Relative Strength of Several Cast-Iron Bearers when subjected to a Transverse Strain. By Charles Parker, Esq., *Fellow, read before the Royal Institution of British Architects, Jan.* 15, 1837.

The object of the paper was to give the results of a series of thirty-four experiments made by Mr. Parker, in an attempt to compare with one another the relative strengths of several forms of cast-iron beams when subjected to a transverse strain: also to ascertain the difference in the strength of their sections when close and when open or pierced, and to give some memoranda of girders that have been executed.

The following comprise the description of beams experimented on by Mr. Parker to obtain the requisite data:—

Complete and open rectangular section—Complete rectangular section with webs in the middle—Complete and open rectangular section with web on upper edge—Complete and open rectangular section with web on lower edge—Complete and open rectangular section with web on both edges—Complete and open rectangular section with spaces between the webs filled in solid.

The experiments were made on models of sufficiently large scale to allow of that precision in adjustment which is essential to obtain an accurate result. The length of each model when cast was two feet five inches and a half, and the depth was one inch and a quarter.

The principle on which the proportions of the sections were formed was to make the width of the complete rectangular beam the basis of every transverse section; consequently this same width is preserved throughout the whole of the several models in the narrow parts of the section, the webs being added in the proper places to make the required diversity of form. The depth and the length of the beam between the bearings in each of the examples were the same. The beams were supported horizontally at both ends, and strained by a force acting perpendicular at the middle point between the props. The quantity of deflection was multiplied by means of a lever index, and the pressure was continued three minutes before any addition was made to the weight. Four experiments were generally repeated of each section, and the strain was increased by fourteen pounds at a time till the beam was fractured. The proportions of the iron used in the castings were equal portions of hot blast calder iron and plate iron, taken from a cold blast cupola.

The following are the results of the experiments on the complete transverse sections:—*

		Wt. of Beam.	Breaking Wt.
		Ounces.	Pounds.
Complete Rectangular	A	28	375
Ditto with web in the middle	B	34	325
Ditto ditto on upper edge	C	34	325
Ditto ditto on lower edge	D	34	550
Ditto ditto on both edges	E	43	750
Ditto with space between webs on both edges filled in solid	F	90	950

It is not intended to illustrate the principle of comparison by any numerical operations, or to form constant multipliers applicable to the strength of each separate section. This remains to be done by future experimentalists, as it is considered that the results which have been obtained are insufficient for that object.

From a cursory inspection of the tables, the following deductions are obvious:—That the strength of a beam to resist a given pressure is not in proportion to the quantity of materials it contains; and, that the power of each section to resist the straining force is obtained more by the proper disposition of the component parts than by the contents of the sectional area.

On comparing the several results, it will be perceived that the strongest form is obtained by the relation that subsists among the parts that make the section E, in which the neutral plane is disregarded, and the surfaces of extension and compression are proportionally increased.

Also in the sections B, C, and D, in which the three planes of the area of a beam are severally enlarged, it appears that the increase of material can be applied with advantage only in the lower surfaces subjected to extension; for, when added in the neutral plane, or on the upper and compressed surfaces, it essentially weakens the beam, and renders its powers of resistance inferior to the plain rectangular section A.

The truth of this conclusion is equally deducible from the proportional increase of the deflections with the earlier weights, in those sections where the lower surfaces are not enlarged. It was perceptible also by the shape and appearance the parts presented where fractured. The whole of the results thus obtained seemed to indicate, that the resistance of the particles to extension is not the same, or equal to the resistance to compression; and on this principle it is suggested that the strongest and most economical section would be obtained by making the upper about half the projection of the lower web.

It is also observable, that the sections A and F, although both rectangular sections, and the latter in the model made three times the breadth of the former, do not preserve the same relative powers of resistance, the section F, with $3\frac{1}{4}$ times the material supporting only $2\frac{1}{2}$ times the pressure; this result makes caution requisite in the use of the tables of the strength of beams that usually accompany works on this subject, wherein it is argued, that as a beam of an inch in breadth will bear a certain weight, so a piece five times in breadth will be five times as much, and the same as any other breadth, forgetting that in a beam of a certain quantity of material, the maximum of strength is obtained by a certain ratio of the depth to the breadth.

The whole of the preceding experiments were made with the middle portion of the section entire; but with a view of ascertaining whether the strength of the material would be essentially impaired by removing that portion of it which lies immediately contiguous to the neutral plane, or between the compressed and extended surfaces, several castings were experimented on. Still, before detailing these results, it appears desirable to give the particulars of two experiments that were made on hollow girders of an elliptical section.

1st Experiment.—Two girders 21 feet 2 inches long each; weight of No. 1, 13 cwt. 1 qr.; ditto of No. 2, 14 cwt. 14 lbs.; distance between the supports, 19 feet 8 inches; space between the two girders, 3 feet; loaded with pig-iron and equally distributed over the whole length: both castings being defective, they broke with the weight of fourteen and a half tons. The deflection in the centre was three-quarters of an inch under the pressure of ten tons. The fracture in both was two feet from the centre.

2d Experiment.—Two girders from the same pattern as above, being sound good castings; the same distance between the supports, and the same space between the girders; the load equally distributed as in the 1st experiment. Weight of 2 girders, 1 ton 8 cwt. 2 qrs.; ditto of each girder, 14 cwt. 1qr.: both broke under the weight of twenty-one tons exactly in the centre of each girder. The deflection in the centre of the last two, during the process of weighing, was 5 tons $\frac{1}{2}$ an inch, 10 tons 1 inch, 15 tons $1\frac{3}{8}$ of an inch, 20 tons $1\frac{3}{4}$ of an inch.

It is scarcely necessary to mention, that the principle of strength in this section is taken from nature, where it is beautifully exemplified in the bones of many animals, in the structure of birds, and in the stems of most plants; but the advantages the form offers are defeated by the

* By dividing the breaking weight in pounds by the weight of the beam in pounds, we obtain the following data as the proportional strength of each beam:—

		Wt. of Beam in Pounds.	Breaking Wt. in Pounds.	Proportional Strength.
Complete Rectangular	A	1·750	375	214
Ditto with webs in the middle	B	2·125	325	153
Ditto ditto on the upper edge	C	2·125	325	153
Ditto ditto on the lower edge	D	2·125	550	259
Ditto ditto on both edges	E	2·688	750	279
Ditto with space between the top and bottom webs on both sides filled in solid	F	5·625	950	172

—Editor.

difficulty of obtaining sound castings, where the length exceeds the distance given in the experiments, namely, twenty feet.

Mr. Parker states, that by taking away the parts about the axis, or hollowing the mass, slightly impairs its power to resist a transverse strain, while it produces a form of section that combines the least quantity of material with the greatest strength.

These two experiments therefore show, that, in the direction of the length, a portion of the neutral plane may be cut away without much injury to the strength of the beam, but as there is often a portion of the neutral plane removed in the direction of the breadth, the result of the experiments before adverted to remain to be mentioned.

Mr. Parker then proceeds to make some remarks on *open or pierced beams*. It has been generally considered, that in pierced beams, the disposition of the middle surfaces of the depth may be regulated by fancy; and that, provided sufficient diagonal and cross-ties are allowed to connect the upper and lower portions, and prevent irregular contraction in the metal, no strength can arise from the distribution of these parts. Leaving this question for future inquiry, it is necessary to mention, that the plan of opening the beams, which was followed throughout the whole of the models, was similar to that recommended by Tredgold. Thus, the rectangular section had five-eighths of the entire depth taken away, and the several remaining portions disposed so as to keep an equal bulk in every part. The apertures had both ends circular, and both sides parallel, with the outer edges, thus connecting and giving stability to the whole beam.

The object now sought, was whether beams, having a portion of the middle cast open, were as strong and stiff as when cast solid, and after many trials the following were the conclusions.*

That beams of equal depth and breadth when cast solid are stronger and stiffer than when cast open.

That equal weights produce equal proportional deflections in the same section, whether cast open or solid.

That the strength and stiffness of the solid to the open section is in exact proportion to the quantity of material used in each section, and which, in the present case, may be numerically expressed as one-third in favour of the solid.

Such are the results of the experimental researches made on this part of the subject, for which, from our prior view, we were little prepared. How far these effects might be modified by a different manner of opening the neutral plane, is matter of conjecture, and can only be determined by experiment. Indeed, from the constant assertions that had been previously made, we were imbued with the idea, that when a certain quantity of metal is cast into the form of a beam of a given depth, it was both stronger and stiffer if *pierced* than it would be if left *solid*. The results have proved this to be erroneous; and should it now be advanced on the ground that the equal quantity of metal, and not the equal depth of the two sections, are to be regarded, still, if found correct, it will not alter the general consequence that may be inferred from the experiments, namely, that into whatever forms the middle portion of the beams may be moulded, the advantage will be comparative, and there will be no deviation from the principle that has been found to operate in the hollow girders.

* We regret that Mr. Parker did not give the particulars of these experiments, as they are most important.—EDIT.

ARCHITECTURAL NOTATION.

SIR,—In your last Number, I find a paper upon *Architectural Notation*, read before the "*Institution of British Architects*," in which is a disquisition upon the adoption of a uniform method of Notation. It does not appear, that of the thirteen modes of notation therein instanced, any difficulty of understanding the intentions of the several writers has been experienced: of these methods, those of Messrs. Stuart, Wilkins, Pugin, Walker, and their associates, have one superiority, in no distinct denomination being set over the decimal parts of inches, which not being of a new *duo*-decimal denomination, it is inaccurate to give them any new denomination, the decimal point (·) explaining to the meanest arithmetician the true fractional value; for the marks (′·″·) or (⁰·′·″·) should, as in astronomy, signify gradual *equal* progression, as from degrees to minutes, from minutes to seconds, &c. The notations of Mr. Donaldson and his associates is, however, the best, for the reasons which I will hereafter show, but then the denomination (″) should be omitted, or, if it be retained, it should be applied to twelfths, and not to tenths of inches.

Although most persons who use duodecimal arithmetic multiply fractional dimensions principally by the rules of *Practice*, or subdivision, still it is very convenient for knowing how to place the several products of the fractional multiplications under their right denominations, and comparatively few persons, who use duodecimal arithmetic know how to do this, in the case of minute parts of inches when multiplied in the regular mode of duodecimals; and this may sometimes be of importance in estimating the weight of metals, and other costly substances. It is no new method to place over feet the mark (⁰), over inches that of (′), over parts or seconds that of (″), over thirds that of (‴), and so on; and this facility results;—for add together the numbers of the two denominations multiplied, and their sum will be the value of the product; thus, feet multiplied by inches will give inches, $({}^{0} + {}' = {}')$; and parts multiplied by parts, will give fourths $({}'' + {}'' = {}'''')$, as will be een by the following multiplication:—

0	′	″	‴	⁗
feet.	inches.	parts.		
1	2	1		
2	4	3		
		3	6	3
	4	8	4	
2	4	2		
2	9	3	10	3

Stuart's method of putting the mark (′) over feet, will confuse a person multiplying, and so will Donaldson's method of putting the mark (″) over tenths of inches. There should, I think, have been no changes introduced in the notation of the volumes in continuation of Stuart's invaluable work; changes too often create, with many persons, doubt and confusion: hitherto, the change in the French measures has caused more trouble and annoyance, both to Frenchmen and foreigners, than any good result will ever repay, besides rendering obsolete a very splendid portion of French scientific literature; while the French long measure, derived from the pendulum-rod, which varies in length in different latitudes, is a very unsatisfactory standard, even within the extent of France.

I am strongly of opinion, that these marks should be abandoned altogether, except in *duodecimal* arithmetic. The words "*feet*" and "*inches*," or their contractions "*ft.*" and "*ins.*," in order to prevent doubt, should always be expressed; and I judge, that no one who knows the superior convenience of decimals for summing up the fractional parts of dimensions, will think of carrying the duodecimal subdivision, in architectural plates, beyond inches; though I believe the mind, in considering fractional quantities, generally refers decimal fractions to halves, quarters, or other vulgar fractions, which are easily formed by bisection or other simple modes.

Yours, &c.,

Gray's Inn, January 20, 1838. ALFRED BARTHOLOMEW.

NEW INVENTIONS, &c.

SIR,—Being particularly devoted to the advancement of the arts, a true lover of novelty, and, moreover, a great rambler, with the organs of acquisitiveness and comparativeness, make me vain enough to imagine that I might be useful to many of your readers, by occasionally forwarding a few of my observations for insertion in your useful and valuable Journal; their tendency being of a practical nature, will, I am sure, be the more acceptable; as I clearly perceive your pages are occupied by articles of that character in preference to those of a more speculative nature. My purpose is a desire to distribute my mite of information to those that need it, and to seek the various novelties, inventions, and improvements that daily take place under our very noses (without our being a bit the wiser), and publish them to the world, or rather to your readers, and thus make myself useful in giving information of any peculiar kind of material, ornament, invention, construction, or what not, that may be discovered in and about the Metropolis, and consequently bring together the manufacturer and the consumer. Now, with regard to my calling, I have the honour of belonging to that profession to whose benefit your work is devoted, and consequently somewhat qualified to judge of the kind of information that is likely to be useful to them. I intend, therefore, if my proposal meets with approval, to visit the several manufactories, and describe, to the best of my ability, the nature, use, and advantages of their several productions. Having now informed your readers of my intentions, I am desirous of obtaining their aid and assistance, and wish that they will, at any time, inform me by letter under cover to your Office, when, where, and how such things that come within their notice may be seen or obtained, and I will immediately visit and report progress, that they may be reported in your future Numbers. I will now proceed to my task, and hope, ere another month elapses, to send you a "sample for approval," having, by running over your advertising columns, already noticed several inventions that deserve to be examined, and if good, to be made public. Yours, &c.

PHILO-TECHNICOS.

We shall be happy to hear from our Correspondent, and receive any letters that may be forwarded for him.—EDITOR.

GREAT WESTERN RAILWAY CARRIAGES.

SIR,—It is with much regret that I observe one particular in your description of the carriages built for the Great Western Railway. This is, that they are eight feet wide, from which it follows necessarily, that they must be mounted upon the top of small wheels, in a precisely similar manner to those on other railways. Thus, the only advantage to be derived from the increased gauge adopted by this Company, will be a wider base. *Some* improvement in the steadiness of the trains' motion will, no doubt, result from this, but surely not (at the high velocity contemplated) to the extent the public

have been led to expect. If, however, the bodies were let down to within a few inches of the ground, between wheels as large (at least) as the propellers, there would still be ample width, and how delightful, how beautifully imperceptible the gliding motion! Probably the expense would be greater, but surely it would be very false economy not to give the present important experiment every chance of success. For combined strength and elasticity, probably no wheels are so well adapted to the purpose as Jones's Suspension. I should think, too, that the evils of a "deep-cranked axle" might without much difficulty be avoided. My apology for troubling you with these remarks must be, that I speak on public grounds, not being in the most distant manner connected with the railway.

I remain, Sir, your obedient servant,

London, Jan. 13, 1838. Φιλο-Βεβαιωτης.

BUNNETT AND CORPE'S REVOLVING IRON SHUTTERS.

Sir,—I have frequently noticed in your valuable Journal advertisements respecting Messrs. Bunnett and Corpe's *Patent Revolving Iron Safety Shutters*; but not requiring any, I did not call at their office before yesterday, when I was pleased to find the several advantages stated by them generally borne out.

I feel perfectly satisfied in my own mind that the simplicity of their principle, and the nature of the materials are such, as to preclude the possibility of their getting out of order: the person in the office pointed out to me the very ingenious contrivance they have recently introduced to *prevent* servants *over winding the shutters* when *raising* or *lowering* them; he also informed me that they have introduced their iron shutters to *circular* windows, which, I must confess, appeared to me almost impossible; and I have no doubt that their ingenuity will be amply rewarded for the trouble and pains they must have taken in bringing their most excellent invention to such a state of perfection. I was also informed that great convenience was afforded by the application of their Patent Shutters to *Iron Fire-proof Safes* (a very large one at that time being in the office).

At one time I was fearful that Iron Shutters would never be brought into general use. I saw (what I considered) insurmountable difficulties, and that to effectually remove the liability to get out of order, to which that description of shutter appeared subject, would require more than ordinary labour and perseverance; but I have the pleasure to find my fears at once dissipated, and that some of the most eminent architects are giving every encouragement to the Patentees of the above shutters by introducing them in those buildings where great security combined with simplicity of action is required.

I should not have troubled you with this letter, was I not aware of the very great annoyance some of the Profession have experienced from having adopted other Iron Shutters, and in some instances been compelled to have them either removed or altered. Yours, &c.

January 24th, 1838. C. S.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

The Annual General Meeting of the Institution was held at their Rooms on Tuesday Evening, January 16, 1838, to receive and deliberate upon the Report of the Council on the state of the Institution, and for the Election of Officers for the ensuing year.

The following Gentlemen were elected Members of the Council for the year ensuing:—

James Walker, Esq., F.R.S., L. & E., President.

William Cubitt, Esq., F.R.S.
Bryan Donkin, Esq., F.R.S., F.R.A.S.
Joshua Field, Esq., F.R.S.
Henry R. Palmer, Esq., F.R.S.
} Vice-Presidents.

Francis Bramah, Esq.	George Lowe, Esq., F.R.S.
J. K. Brunel, Esq., F.R.S.	John Macneill, Esq., F.R.A.S.
William Carpmael, Esq.	W. A. Provis, Esq.
Lieutenant Denison, R.E.	James Simpson, Esq.
Joseph Locke, Esq.	Robert Stephenson, Esq.

A new Regulation and By-law was adopted for the introduction of a new class of Members denominated "Graduates," who shall be persons pursuing a course of study or employment in order to qualify themselves for following the profession of a Civil Engineer. A change has also been made in the constitution of the Council by the admission thereto of two additional members from the class of Associates, the Council having previously consisted of members of the first class only.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an Ordinary Meeting, held 15th January, 1838, at the Rooms in Grosvenor street; P. F. Robinson, Esq., V.P., in the chair.

The following gentlemen were balloted for, and declared to be duly elected as fellows:—John Foulston, Esq., of Plymouth; Samuel Beazley, Esq.; of Soho-square.

Several donations were announced as having been received since the last Meeting:—Edward Edwards, Esq., Catalogue of medals struck in France, Signor Campanari, Copy of Essay by Signor Secondiano Campanari on the Fictile Vases found in Etruria; Joseph Bonomi, Esq., model of an obelisk near Cairo, with a description and impression in plaster of a medallion of Her Majesty, executed in the Egyptian style; J. Harrison, Esq., a very fine cast of the bust of the late Thomas Harrison, Architect of Chester; Mr. Willemint, a coloured print of the altar window at St. Peter's Church, Hampton Lucy, Warwickshire; H. E. Goodridge, fellow, three specimens of stone from Tisbury, Wiltshire; James W. Wild, associate, copies of works in Worcester and Lincoln Cathedrals, by his father, the late Mr. Charles Wild; G. Godwin, Jun., associate, Part 13 of the Churches of London, and several specimens of building stones and granite.

The following papers were read:—

On the Restoration of the Temple of Jupiter Olympius at Athens, illustrated by some beautiful drawings, by Charles E. A. Blair, Esq., Architect.

On the relative strength of cast iron beams when subjected to a transverse strain, being the result of a series of practical experiments, illustrated by the original models, by Charles Parker, fellow.

The following drawings, which had been sent in for the Soane medallion, were exhibited:—

Two series, being restorations of the Abbey of St. Mary, York; one ditto, being a restoration of Kirkstall Abbey, Yorkshire; one ditto, being a restoration of Llanthony Abbey, Monmouthshire. The paper accompanying one of the first subjects was read by P. F. Robinson, Esq., V.P., who made some preliminary observations and remarks connected with the Abbey.

ARCHITECTURAL SOCIETY,

35, LINCOLN'S-INN FIELDS.

The Monthly Meeting for the introduction of visitors was held at their Rooms, on Tuesday, January 2nd, 1838. George Mair, Esq., V.P. in the chair.

Letters were read from the Committee of the Travellers' Club, also from Charles Barry, Esq., Architect, expressing their consent and approbation to the student members measuring the Garden Front of the same, for the purpose of competing for the copy of Mr. Owen Jones' book, agreeable to the notice given at the last meeting. The election for two student members then took place, as also the balloting for the last subject agreeable to the premium to be given by George Mair, Esq., V.P. An interesting paper was then read by T. H. Wyatt, Esq., V.P., entitled "Considerations on the Commencement of an Architect's Practice."

The subject for the members' sketches was then announced, viz.—"A design for a nobleman's mansion in a public square, with stables in rear."

Students' subject—"Design for a gamekeeper's lodge, with plan, elevation, and section."

The Chairman then called the attention of the Meeting to Messrs. Fair and Baillie's Patent Glass Ventilator; also Messrs. Bunnett and Corpe's Patent Revolving Safety Shutters and Blinds, in iron and wood;* also iron fire proof Safes, by Messrs. Bunnett and Corpe, both of which were fully explained by the respective patentees.

Models were also exhibited for improvements in the construction of French Casement Sashes, so as entirely to exclude wind and weather.

Some interesting Prints of ancient Tessalated Pavement were exhibited by Mr. J. H. Hakewill, member.

Also several sketches by students, in competition for George Mair's prize.

MANCHESTER ARCHITECTURAL SOCIETY.

The first Annual Meeting of this Society was held in their rooms, Mosley-street, on Wednesday, January 3, the President, Richard Lane, Esq., in the chair. The Report of the council gave a very satisfactory account of the proceedings of the past year and a flattering statement of the prosperity of the Institution. The library now contains nearly 150 volumes of the best standard works on architecture; and the Royal Institute of British Architects in London have expressed a wish to open a correspondence, as well as offering admission to their meetings to any members who may visit London. Five new members were elected, after which the several officers were appointed for the year, and the thanks of the Meeting were presented to Mr. Lane, Mr. James Heywood, Mr. J. W. Frazer, and many other gentlemen who have made donations to the funds and library.

MEETINGS OF SCIENTIFIC SOCIETIES.

Institution of Civil Engineers, 1, Cannon-row, Westminster, every Tuesday Evening, at 8 o'clock.

Royal Institute of British Architects, 16, Grosvenor-street, Grosvenor-square, Monday Evening, 8 o'clock, February 12th and 26th.

Architectural Society, 35, Lincoln's-inn-fields, Tuesday, February 13th, at 8 o'clock.

Society of Arts, Adelphi, every Wednesday, 8 o'clock.

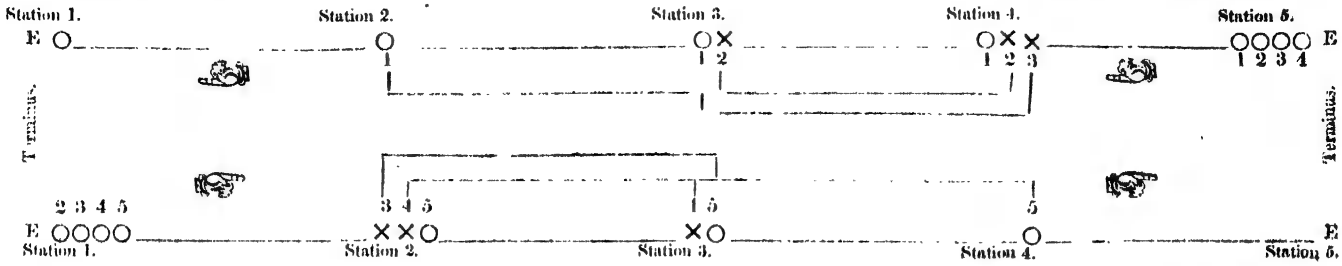
* These Iron Shutters are being very generally introduced in all the principal offices in the City; the advantages are very great, not only for their security against depredators and fire, but also for the convenient manner they may be closed from the interior in a few seconds, and concealed either in the entablature or over the soffit of the window.

LONDON AND BLACKWALL COMMERCIAL RAILWAY.

REMARKS ON THE REPORT OF MESSRS. G. STEPHENSON AND G. P. BIDDER. BY AN OLD ENGINEER.

SIR,—The Report of Messrs. Stephenson and Bidder to the Directors of the London and Blackwall Commercial Railway Company, on the best mode of working that line, has fallen under my notice, and as I do not concur in the view of the subject in question taken by those gentlemen, and as the decision of the Board must influence the interests of the shareholders in a very high degree, in the event of a wrong calculation being adopted, I make no further apology for requesting the insertion of this Letter into your Journal.

The subject matter for consideration is stated in the second paragraph of the Report.* The trains are assumed to start every quarter of an hour, during business hours, from each terminus, and for the remainder of the day, every half hour; the time occupied in each trip, it is proposed, should not exceed twelve minutes. The road proposed is set forth and explained in the Report (paragraphs 12, 13, 14, 15, 16). These portions of the Report place the question at once before the reader as it is, whether the locomotive or stationary engine, for a short and busy line, is the best of the two; it will, perhaps, assist us in understanding the argument to refer to the diagram below, which displays my view of Messrs. Stephenson and Bidder's plan.



The numbers 1, 2, 3, 4, 5, represent the termini, and OOO, intermediate stations; the letter E the engine stations, and the indexes (☞) the line of direction of the rope and train respectively; the letters O represent the trains, or carriages, destined for each station, and are numbered according to the station they will stop at. Thus, supposing the whole train of carriages to start at the same moment, the detached carriages will reach the termini successively, and the four conjoined carriages will be thrown off the ropes as they successively arrive at their places of destination: then, the return line will present the aspect of the second diagram, the same arrangements will take place, and the carriages will be left at the stations for the operation to be again repeated; by this means, the arrangement is simple enough, and the journey from terminus to terminus may be made in 12 minutes, and passengers taken up, and set down, between the termini and the intermediate stations. But suppose it is required, as stated in paragraph 20 of the Report, that passengers be taken up and set down at intermediate parts of the line, for example sake, between the West India Docks and Limehouse, or stations 4 and 3, or the West India Docks and Cannon Street Road, or stations 4 and 2, the distances between each place being a mile; then, auxiliary carriages must be provided, represented by ×, which must be thrown off the rope as they arrive at the stations to unload; and then, if only two lines are employed, these auxiliaries will be stationary upon the line, whilst the Blackwall train is travelling only a mile behind, at the rate of a mile in two and a half minutes: thus, unless the passengers alight and the carriage be again connected with the rope (running at the rate of twenty four miles per hour), a collision must take place; but, perhaps, the other side may propose to get out of this dilemma by taking the West India Dock passengers, requiring to be set down at Limehouse, to London, and then setting them down by the London return carriages, thus making it necessary to change coaches; and this could not be done by the return train, as the carriages do not stop near the engine, but are impelled by *momentum*, between the Minories and Fenchurch Street; so that, if a person set out from the West India Docks, it would take him a quarter of an hour to go to Fenchurch Street, and half an hour to get to Limehouse (losing one train), being conveyed by the railway a mile in three-quarters of an hour, about the time he could walk double the distance without the least difficulty. The only way then to get out of this dilemma, is to have four sidings or collateral lines for the auxiliaries to draw out of the main line; but then this is just the same as forming four lines, and neutralizes the proposed system altogether. More than this, the space which must be left in the diagonal rail for the rope to pass, must be replaced like a switch, before the carriage crosses over, which will be an arrangement very likely to be neglected, when the most disastrous consequences may result.

I hope I have thus shown that Messrs. Stephenson and Bidder cannot possibly carry into effect two of their proposed objects, viz.—take up and put down passengers between intermediate stations, without four lines of rails, and without losing time.

Let us now see how this object can be effected by the locomotive.

If a single train is employed from end to end, to stop and take up passengers at the various stations, then, of course, the time between the termini will be prolonged, but it need not be more than two minutes at each station, which would make it eighteen minutes for the whole line; but if it should prove that the West India Dock passengers were sufficiently numerous to warrant the arrangement, an engine could start from that point and take up the passengers as it went along, leaving the Blackwall trains to run the whole distance without stopping; neither will there be any collision here, for by the West India Dock's train, following the Blackwall train, all possibility of accident from this cause will be avoided; and thus the time between Blackwall and London may be twelve minutes, whilst the West India Docks and London will be fourteen minutes; and by refining still further upon this method, by a train starting from Limehouse to take up the intermediate passengers, and this train following the quick trains, the West India Dock train may run through in ten minutes, Blackwall in twelve minutes, and Limehouse in ten minutes, starting either after the West India Dock, and before or after the Blackwall trains; and all this may be done upon two lines without sidings or collateral lines. It is thus evident, that if it be an object to reduce the width of the viaduct, it can only be done (embracing all the objects of the Company) by employing locomotive and not stationary engines, in the manner proposed by Messrs. Stephenson and Bidder.

The method proposed, of working upon the same line backwards and forwards by a tail rope, has this very great disadvantage; that you are limited in the number of trains you can despatch from each end to the time occupied in travelling between the extremes; in the present case, the limit has been chosen, but an endless rope being employed up one line and down the other, and kept in perpetual motion, trains might have been sent off every minute, and it would only have been necessary to have provided for the case of the train starting gently, without stopping the rope in a manner similar to that practised every day in manufactories. By the locomotive system, each train being independent, acts upon the accommodating principle, so that the only limit, is the distance one train ought to keep from the other (half a mile), which would allow of trains starting every minute, as in the other case.

Aware of the objection against the pullies which support the rope from the noise produced throughout the line, these gentlemen state, that "the pullies for carrying the ropes admit of being constructed so that all inconvenience from this source would be entirely obviated; so that, indeed, the inhabitants adjoining the line would be utterly unconscious of their action. On the other hand, it is clear that the occasional nuisance arising from the expulsion of steam and ashes from the locomotive engine funnel would be totally avoided." This I doubt very much, even supposing some method contrived by which the noise from the axles may be prevented, the rapid revolution of the pulley itself would make such a humming noise as would prove "a just cause of complaint" to the inhabitants upon the line. Perhaps these gentlemen have never heard the whiz produced by a cannon-shot, or even a bullet through the air, produced from the mere friction of the air upon the surfaces of either; I have heard such repeatedly, and should be very sorry to inhabit a house in which such sounds were perpetual.

The steam and ashes from locomotives, if a source of annoyance, is the fault of the contriver or manager. Hancock has proved that a locomotive may be so quiet, that it shall make no more noise than a condensing engine; and as regards the nuisance of the engine blowing up, this is a fault of construction also, and a loss of power likewise, which might be very easily removed in the first case, and employed to a very useful purpose in the second.

The enlargement of the curves, so earnestly recommended, is needed more for the stationary than the locomotive system, because the locomotive can adapt its speed to all conditions of the ground it is going over; not so the stationary engine, which must be worked at an almost uniform velocity; and although Messrs. Stephenson and Bidder may fence off this objection by saying they will provide signals on the rope, or some system of adjustment upon the engine, each remedy is so very faulty, that I am certain both would fail in practice.

Again, as regards the chances and the nature of accidents to both systems, the locomotive is decidedly the most safe, supposing a broken rail, or a carriage thrown off the line; the stationary engine, two miles off, could never be stopped in time to prevent mischief, and it is not answering the case that the means may be provided to throw off the connexion of the train with the rope at a moment's notice; this may succeed in ninety-nine cases, but at the hundredth it may fail, and then the train would be dragged along and

* We have omitted printing the passage of the Report, having in another part of our Journal given it in full, and have numbered the paragraphs, so that any part of it may be the easier referred to.—EDITOR.

dashed to atoms without remedy; the accident would assume the character of those awful cases, when a man's apron catches in a strap in the machinery of a manufactory, dragging him round the pullies, and tearing his body to pieces.

The locomotive, on the contrary, has provided within itself the same means of stopping or throwing off the power at will, and in the case of running off the line, the train will be very soon stopped by the resistance of the ballasting, and that by a comparatively insensible action, and the less dangerous consequences, under all the circumstances of the case, are likely to ensue.

There is no doubt that a fixed engine is more economical than a locomotive, as at present constructed; but I am very much mistaken if the difference will always exist, or even until the Blackwall Railway shall be formed. And I think Messrs. Stephenson and Bidder are not justified in taking credit for the abolition of the hoisting machinery at the West India Docks, inasmuch as their terminus being upon the same level at Fenchurch Street as the other plan, they are converting the entire line into a hoisting machine, and if my assumption is correct, no possible advantage can arise; for if the difference of level between the West India Docks and Fenchurch Street is the same in both plans, the power required to lift the load, or the momentum of the machine, must be the same, whether it is up the perpendicular, or along the diagonal of the triangle representing the two forces.

It is true, the Blackwall engine is less powerful than that at the Minories by 50 horses power, the difference in tractive force being made up by the inclination of the plane; but, unless the two engines are connected together, so that the weight of the waggons on one side balance that of the waggons on the other, the weight of the waggons towards London will be always acting disadvantageously, and the engines will lift every journey, towards London, the entire train of coaches, waggons, and passengers, a vertical height equal to the difference of level of the two termini: now, by the hoisting machinery, the goods only are lifted up this difference, the passengers lift themselves, so that the loss of power would be comparatively immense on the side of the proposed system. Again, a judicious engineer would always, if possible, give the inclination of his line in favour of the heaviest load. London being the great consumer,* the provisions and goods coming towards London will be very much greater than the provisions and goods going from London, particularly the goods imported into the docks, such as the heavy articles, sugar, logwood, iron, stone, &c.; thus, in this view of the case, the alteration or lowering the levels towards Blackwall very ill-advised.

I am surprised, that an engineer who has had the very extensive experience that Mr. George Stephenson has had, should depart in this instance from the evident principle, which I can scarcely think he has not observed, that the word power, as applied to a railway, refers rather to its levels than its engines, and that this point ought never to be lost sight of. He cannot fail to have observed, that the inclined planes of the Liverpool and Manchester Railway cause greater wear and tear to engines, and greater comparative expense in working, than all the rest of the line put together; but, in this instance, he rejects the level of 12 feet per mile, and refers to the Euston Square plane of 80 feet per mile, as a favourable illustration of the principle he advocates, and for no other reason but because of the superior advantages of the stationary over the locomotive engine, as a mere machine.

The Directors, in the preliminary paper accompanying the Report, make the following observations:—"The Report which accompanies this, is the result of that application; and, while the Directors congratulate the Proprietors upon its very important and satisfactory contents, they are enabled to state, that no Report was ever prepared with greater consideration, anxiety, and labour, and they therefore confidently recommend it to the adoption of the Proprietors."

I think, if my position cannot be disproved, the Directors have little ground for their expressed congratulations. In my judgment, a great question has never been more unfortunately treated; and I would earnestly recommend the parties interested, to subject all the points stated to their most serious deliberation, for if they should act upon this Report, I fear they will have but too much reason to regret their decision.

One word, in conclusion, upon the paragraph respecting the comparative success or otherwise of the Greenwich Railway. That Railway has never had justice done to it, either by the public or the Directors; the management hitherto has been most defective; the engines upon the line, excepting two by Forrester, of Liverpool, are very inferior; but notwithstanding these disadvantages, with only four engines on Easter Monday of the last year, 23,000 passengers were carried in one day, and without a single accident, in the teeth of the most defective arrangements. There has been nothing but a perpetual series of alterations in the operations; and there is not, at this moment, any person in charge of the mechanical department, qualified by experience or talent to so important an office; it is to be hoped that the new Board of Directors will, by their judicious measures (and they have made a few very proper dismissals), place, in a true light, a work, which ought, and might be, a pattern to all other undertakings of a similar nature.

AN OLD ENGINEER.

LONDON AND BLACKWALL COMMERCIAL RAILWAY.

REPORT OF MESSRS. STEPHENSON AND BIDDER.

1. Gentlemen,—In pursuance of your resolution, that we should furnish the Board with a written Report as to the best mode of working the Blackwall Railway, and point out any improvement that might occur to us in the construction thereof, we have examined the plans and sections of the London and Blackwall Railway, and have also had various communications with Mr. Tite respecting the property on and adjoining the railway: and we avail ourselves of this opportunity of expressing our thanks for the obliging manner with which he has given us much useful information.

2. With reference to the most important point on which you have done us the honour to request our opinion, viz.—the best mode of working your line of railway, we have to observe, that our attention has been devoted exclusively to the relative advantages of employing stationary or locomotive power; deeming one or the other of those to be the only practicable and efficient mode of working this line.

3. The Commercial Railway, as at present designed, is to extend from the Brunswick Wharf, Blackwall, to a depôt adjoining Fenchurch Street, in London, a distance of about three and a half miles, to be built on arches, and having gradients rising on an average twelve feet per mile; the line being tolerably direct, though there are, in its course, curves of about one thousand yards radius.

4. By the Company's prospectus, we find that the expected traffic is estimated at 13,500 passengers and 480 tons of goods per diem.

5. With the view, however, of keeping our conclusions upon the comparative powers of stationary and locomotive engines on the safe side, we have assumed the traffic at 8,000 passengers and 250 tons of goods per diem.

6. It must not be inferred from this, that we imagine the former statement of traffic to be exaggerated; our intention in the reduction being solely to prove the superiority of the stationary engine system upon the lesser amount of traffic, and *à fortiori*, demonstrate its greater eligibility for the larger quantity.

7. For this amount of traffic, and to meet the public convenience, we assume that it will be necessary to have trains to start from each terminus every quarter of an hour, during the business part of the day; and that for the remainder, it will be sufficient to have half hour trains.

8. We also assume the importance of the West India Dock traffic, both for passengers and goods, to be such, that it must be deemed a *sine qua non*, that the West India Dock passengers should be conveyed with the same regularity and speed as those passing from terminus to terminus.

9. Rapidity of conveyance being the chief inducement for the use of railways, we consider that the time occupied on this railway, from terminus to terminus, should not exceed twelve minutes. This, if the locomotive system be adopted, would require the engines and trains to travel with a minimum velocity of thirty miles per hour, when at full speed; otherwise the delay occasioned by the necessity of stopping at the West India Docks, would prevent the journey from being performed within the above limit. At this great speed, it is highly desirable that no curve on the line should be of less than one mile radius. There can be but one opinion of the manifest advantages which would follow the enlargement of the curves on your line of railway; and we are aware that they have been adopted for the purpose of avoiding greater interference with valuable property; if, however, the width of the railway be reduced to the extent we shall suggest, these curves may be got rid of without rendering such interference necessary.

10. We are aware that a highly respectable authority has stated that three lines might be sufficient upon the locomotive system; but it was added, that the width between the rails should be increased. We do not see how the increasing the width between the rails is to meet the necessities of the case; but are satisfied that it would then inevitably become still more desirable to have the curves of enlarged radii.

11. Mr Cubitt having, therefore, notwithstanding his proposal to reduce the number of lines, still recommended a width of forty-five feet for the railway, being, in fact, the same as that chosen by Sir John Rennie, and estimated for by him, we have assumed this width in our estimates for the locomotive system.*

12. If the stationary engine system be adopted, we should recommend that the engines be placed at or near to the Minories in London, and at or near to Brunswick Street, at Poplar, with ropes extending between these two points; leaving the spaces included between the Minories and Fenchurch Street, at one end, and between the Brunswick Wharf and Brunswick Street, at the other (which are composed of curves of small radii), to be worked in one direction by momentum and in the other by gravity, as at present exemplified in the London and Birmingham Railway, at Euston Square.

13. The ropes would be wound round drums of a large diameter, and we should propose to work this line by what is called a tail rope; that is, a rope attached to the train, by which it is drawn on the return journey, thus, in fact, a rope will be always extended the whole length of the line between the Minories and Brunswick Street, Poplar.

14. By this arrangement carriages can be attached or detached, at any intermediate point of the line as well as at the termini, upon the same principle that the trains on the London and Birmingham Railway are attached to the rope on the extension of that Railway to Euston Square.

15. Capability would thus be afforded to the Company of increasing their intermediate stations, when their depôt establishment is properly organized, and sufficient inducement in point of traffic has been ascertained to render it desirable. By means of the stationary engines and ropes disposed in the way before specified, the taking on carriages of goods and passengers at all such points as may hereafter be determined upon, can be effected without any stoppage of the intercourse between the extremities of the railway; and the extreme velocity of the rope, therefore, need not exceed twenty-five miles per hour, in order to perform the journey in twelve minutes. The practicability of attaining this velocity, is already proved by the experience of the London and Birmingham stationary engine plane, where a gradient of eighty feet per mile, and with two engines of only sixty-horse power each, is travelled at a speed of twenty miles per hour; and, as the gradients on this railway would be very considerably less, the speed could, as a matter of course, be proportionably increased.

16. Upon this system there would be no necessity for more than two lines of rails; and if the previously assumed space were taken for the lines, the width would not exceed twenty-two feet; but we are of opinion that a greater width should be taken for two lines, and we have assumed twenty-nine feet to be essential, and have made our calculations thereon.

17. Having made these introductory remarks, we shall proceed to the comparison of

* By the evidence given before the Committee of the House of Commons, session 1836, the quantity of goods delivered by land *out* of the East and West India Docks *for* London, is 1[illegible],737 tons; and the quantity of goods delivered by land *from* London *to* the East and West India Docks is 18,638 tons.

* On reference to Mr. Tite's evidence, we find that his estimate of the proposed extension to Fenchurch Street applies to a width of viaduct of 40 feet to include three lines of rails only, and these of the width of 5 feet. On consideration, however, that the orginal estimates apply to that part of the line between the Minories and Blackwall, on which portion only we have estimated the saving effected by adopting the stationary-engine system and being of opinion that four lines of railway would be found necessary were locomotive power resorted to, we do not think it would be fair to state the saving in the width of the viaduct at less than 16 feet.

the relative merits of the stationary and locomotive systems, as applied to this railway. To render our observations the more distinct, we shall arrange them under the following heads:—

1st, *Relative Speed;* 2nd, *Relative Working Expenses;* 3rd, *Relative Cost of Construction.*

I. Relative Speed.

18. As an abstract question, each system can give any velocity which the public wants can demand. In the present instance, we have assumed that it is essential that the trip from Blackwall to London should be performed in twelve minutes, and that the trips should be repeated every quarter of an hour from each end. By the stationary engine system, with engines of two hundred and fifty-horse power at the Minories, and of two hundred horse power at Blackwall, this can be accompanied with a train of one hundred and thirty tons gross load, or with a train of one thousand passengers; and this load might be materially increased, without prolonging the journey more than one or two minutes at most.

19. Upon the locomotive system (supposing that, to ensure regularity, the same speed and punctuality will be demanded in each direction), the capability of the engines is necessarily limited to the loads they can draw from Blackwall to London; which, it is to be observed, is against an inclination of twelve feet per mile; and our opinion is, that the extreme load to be attached to the locomotive engine to admit of its performing the trip in twelve minutes, should not exceed thirty-five tons gross, or two hundred and fifty passengers.

20. To provide, therefore, as well for those cases, when so many as one thousand or more passengers will have to be conveyed on one journey, as for the accommodation of passengers requiring to be taken up and set down at intermediate parts of the line, (which could only be accomplished by separate sets of rails devoted to that traffic and the carriage of goods,) it would, in our opinion, be absolutely necessary, that if it is to be worked by locomotive power, the railway should be constructed with four lines of rails; whereas, by the use of stationary engines, two lines would be amply sufficient to meet all possible exigencies. Undoubtedly there may be occasions when a variety of favourable circumstances will combine to permit the above load for locomotive engines to be slightly increased; but, on the other hand, it will more frequently happen that it will require to be reduced in a much greater degree. From such fluctuations, the stationary engine system is almost, if not wholly, free.

21. Neither system is exposed to serious derangements: though even on this head, in our opinion, the advantage, slight as it is, will remain with the stationary engines.

II. Relative Working Expenses, and Primary Cost of Establishment.

22. With a view to determine this important question, we have made use of the experience afforded by railways in operation wherever such information is available; and though there is not any railway strictly analogous to the London and Blackwall, we have applied the results of such experience, allowing for variation of circumstances, and the peculiarities of the case under consideration.

23. The calculations made upon these data have satisfactorily proved, that the annual expense of maintaining and repairing the locomotive engines required for this line, and keeping them at work, would amount to 23,000*l.* per annum; whilst the stationary engines would be worked and maintained for 11,000*l.*; to which must be added, 1000*l.* per annum for replacing the ropes. To uphold the railway, and to keep the permanent way in repair for the use of stationary engines, would cost 1500*l.* per annum less than if locomotive engines were used, making a total difference in favour of stationary engines, of 12,500*l.* per annum.

24. To establish the stationary engines with the requisite buildings and duplicates would require 25,000*l.*; and to purchase ten powerful locomotive engines, with the requisite water stations, repairing sheds, &c., would cost 20,000*l.*, to which latter sum should be added the expense of erecting the hoisting machinery at the West India Docks; and the annual cost of working the same should also be added to the difference in favour of the stationary engine system, under the head of working expense.

III.—Relative Cost of Construction of Viaduct and Railway required by the respective Systems

25. Prior to entering on the investigation of this head of comparison, we shall allude briefly to the peculiarities of each system which affect the costs of construction.

26. The locomotive engines require that, whatever may be the attendant expense, the gradients should be so modified and reduced as to admit of their efficient operation, otherwise the utility of these machines must be greatly diminished, and their working expenses augmented; whereas, the stationary engine system admits of the gradients being modified to a considerable extent, without affecting its useful and efficient operation. As an instance, we may again refer to the London and Birmingham Railway extension, on which there is a gradient of eighty feet per mile.

27. In the present case, the only limit to the most economical modification of the levels of the railway for adaptation to the stationary engine system, is the prescribed mode of crossing streets and roads. But even within this limit, the saving would be most important, and would be accompanied by other advantages hereafter adverted to: this saving would be increased, if permission could be obtained to cross under instead of over (as at present proposed) Brunswick-street, Poplar, and the road east of the West India Dock Company's reservoir.

28. A most important saving in the cost of construction will attend that system which requires fewest lines of rails, and consequently the least width of viaduct; and assuming that the views previously taken in this Report are correct, it would appear that two lines are all that are required by the stationary engine system; whilst the locomotive system renders four lines essential; and that therefore a saving of at least sixteen feet in the width of the viaduct would be effected by the use of stationary engines.

29. The saving thus attained, by narrowing the width of the viaduct, and lowering it as far as the powers of your Act of Parliament permit, would amount to 150,000*l.*; to which, if the before-mentioned thoroughfares are permitted to be slightly raised, would be added 23,000*l.*, making a total saving of 173,000*l.*, exclusive of that effected in the cost of the property to be purchased.

30. We would further observe, that if the works were so materially reduced, the whole could be completed in eighteen months.

31. Summary.—We thus collect that, under the three important heads of speed, working expenses, and cost of construction, the stationary engine system is capable of producing equal speed with the locomotive; whilst the stationary engine system admits of being worked at a charge of 12,500*l.* less per annum than the locomotives, and in construction a saving of 145,000*l.* would be effected within the powers conferred by your Act of Parliament, besides the saving in the cost of the property to be purchased, and also exclusive of the expense of erecting and working the hoisting machinery at the West India Docks; and that, provided the Company obtain the privilege of passing under the West India Dock Road East, and Brunswick-street, Poplar, a total saving of 108,000*l.* would be effected, exclusive of the expense of erecting and working additional hoisting apparatus at Blackwall, as well as of the less cost of property required.

32. Next, that in addition to the decided advantages attending the stationary engine system on the above important heads of comparison, it would also afford the means of providing as many intermediate stations as might be found requisite, and thus occasion an increase of traffic to the railway, and consequently an increase of accommodation to the public.

33. That, moreover, by being on a lower level at the West India Docks and Blackwall, it admits of a readier communication with the warehouses of the former, as well as with any additional wharfs which may be constructed towards the West India Dock entrance at the latter. In fact, it admits of goods being placed into waggons at the West India Docks, and removed to London, nay, to the warehouses of this Dock Company, in London, without transhipment and without the intervention of any cumbrous machinery whatever

34. Before concluding this report, we would add a few general observations, with a view of dispelling some misapprehensions which may exist respecting the introduction of stationary power.

35. It has been supposed by many, that great speed is incompatible with stationary engines and ropes. To this we would reply, that it is impossible to adduce a single fact or reason for this supposition; and, as conclusive testimony, we would once more refer to the stationary engines on the London and Birmingham Railway; which, with the unfavourable gradient of 80 feet per mile, yet produce a velocity of twenty miles per hour; and had the engines been of greater power, this speed would be proportionably increased. It has been stated, that the noise attending stationary engines is greater than that of locomotives; because, whilst in operation, the noise is maintained constantly throughout the whole line as far as the ropes extend; whereas, it is alleged, that the locomotives are only heard whilst passing. In reply to this, we can only express our decided conviction, that when it shall become an object, as it would in this case, to obviate all just cause of complaint, the pullies for carrying the ropes admit of being constructed, so that all inconvenience from this source would be entirely obviated; so that, indeed, the inhabitants adjoining the line would be utterly unconscious of their action. On the other hand, it is clear that the occasional nuisance, arising from the expulsion of steam and ashes from the locomotive engine funnel would be totally avoided. But we must go further and observe, that the greatest complaints occur against railways when their stations are situated in a crowded neighbourhood, and are produced by the steam blowing off whilst the engines are waiting for the trains, and from the whistles they blow as signals of their approach; whilst the stationary engines cannot be heard out of the building wherein they are erected As an instance, at Camden Town Station, you may actually stand immediately over the engines while in full work, and yet be ignorant of their vicinity.

36. Looking to these circumstances, and collecting that, by the plan proposed there will not be any of the machinery or ropes nearer the London terminus than the Minories, it seems clear that the clause in your Act of Parliament, requiring you to buy all property lying within fifty feet of your line, if injury can be proved, could never come into operation, as there would not exist any just cause of complaint.

37. In conclusion, gentlemen, we beg to recommend, for your adoption, the stationary engine system; under the certain conviction, that you would thereby accomplish your object in the most efficient manner, and with the utmost economy, both as respects cost of construction and working expenses.

We have the honour to be, gentlemen, your most obedient servants,

January 6th, 1838.

GEO. STEPHENSON,
G. P. BIDDER.

THE GRAND CALEDONIAN JUNCTION RAILWAY.

As this subject is at the present time exciting a powerful degree of interest, especially amongst our northern friends, we have much pleasure in laying before our readers Mr. George Stephenson's Report and observations on the route and merits of the two proposed Lines; Mr. Locke being also engaged to find a line to unite the Southern Main Trunks with Scotland

MR. STEPHENSON'S REPORT

TO THE WHITEHAVEN COMMITTEE OF THE CALEDONIAN JUNCTION RAILWAY.

Gentlemen,—In compliance with my instructions from the Caledonian Railway Committee of the 1st of September, 1836, which at that time I was not able to fulfil owing to my numerous engagements, and also in compliance with the request of the Whitehaven, Workington, and Maryport Railway Committee of the 6th of June, 1837, that I should make an ocular Survey of the Country between Lancaster and Carlisle, by Ulverston and Whitehaven; and also between Lancaster and Carlisle, by Kirkby Lonsdale and Penrith, with a view of completing a Railway Communication between Edinburgh, Glasgow, and London, on the western side of the island, and that I should report to you my opinion as to the practicability of the two routes, and which I would recommend should be adopted as the best line for the promoters and the public.

I have now to report to you, that I commenced my survey from Lancaster on the 1st of August, 1837, and proceeded to Poulton, and round the Bay of Morecambe, by Silverdale, Cartmel, and the point of Humphrey Head, across the Ulverston Sands to Ulverston.

I afterwards examined the peninsula between Morecambe Bay and the Duddon Sands. I then proceeded to examine the Lakes of Windermere and Coniston, to see if it were practicable to obtain a line in that direction, but I found no outlet at either place. I then proceeded from Ulverston, and crossed Duddon Sands at the High Ford, and travelled round Blackcombe by Bootle to Ravenglass, making a close examination of the coast in that quarter; and from thence by Drigg, Calder Bridge, St. Bees, and on to Whitehaven. I have also examined the different valleys presenting themselves by Egremont and Hensingham, and the country between them and Cockermouth.

I have already reported to you on the Line between Whitehaven and Maryport, from a Survey made by Mr. Hall, and after my examination of the country I have no hesitation in recommending it to you, as the best Line between Maryport and Whitehaven. And as an Act has already been obtained for a Railway between Maryport and Carlisle, the levels of which are known to be favourable, and the execution easy, it is unnecessary for me to enter into details on that point. The Company are making arrangements to proceed with the execution of the works.

From Carlisle I proceeded to examine the country southwards, and followed the course of the river Petril to Penrith, passing over Shap Fells, and thence into the valley of the river Lune, by Kirkby Lonsdale to Lancaster.

I will now lay before you the course the Railways ought to take through the country which I have examined, describing the routes of the Lines, with the merits and objections to each.

Commencing with the Coast Line at Lancaster, the Railroad should cross the river Lune on the west side of the town, and near the warehouses at present adjoining the river; it should then pursue its course through a very favourable country by Terrisholme, to near Poulton. This portion of the Line from Lancaster would be very nearly level.

At Poulton the sands commence, and the Line should proceed across them in a segment of a circle of about five miles radius, to Humphrey Head, from which place the most favourable course is across the Winder Moor marshes to Chapel Island, and forward to the mouth of the brook which runs down from Swarthdale to the coast, and following nearly the course of that brook, by Swarthdale and Pennington. From this point to Lancaster the country is nearly a dead level. From near Pennington to Kirby Ireleth the ground is rough, and deep cutting, with some tunnelling, would be required. This is a distance however of only two miles.

In these two miles iron mines are met with, which I think might be opened out with great advantage to the proprietors.

The Duddon Sands would then have to be crossed, the distance over which is a mile and three quarters.

From the Duddon Sands to near Bootle the Line runs along a valley about a mile from the shore, and parallel to it. From Bootle it runs in a direct line to Ravenglass, where it crosses a small bay running into the land, and proceeds between Drigg and the coast, in almost a direct line to St. Bees. A portion of this distance it runs almost along the beach where the sea is making land, and there is no danger of its washing. The Line, leaving St. Bees to the west, enters a beautiful valley which runs to Whitehaven, which town it ought to pass to the east of the Castle, cutting into the side of the hill sufficiently deep to hide it from the view of the Castle. It would then join the Line from Whitehaven to Maryport behind the Ropery. The Line I have been describing would run on almost a dead level from Lancaster to Maryport, and I believe in no part more than forty feet above the level of the sea. From Whitehaven to the Duddon Sands the cost of making the Railway would be much below the average of the general cost of Railways. The crossing of the sands would be the most expensive portion of the Line, but the quantity of land reclaimed from the sea would more than compensate for the expense incurred in crossing them.

I will make a few observations at the termination of this Report relative to the manner in which I would execute the works across the sands, and will now give you my opinion as to the direction of a Line from Lancaster to Carlisle, by way of Penrith.

Commencing at Carlisle, the ground is favourable along the valley of the river Petril as far as Penrith. At this town expensive and difficult ground begins to show itself. Two Lines present themselves here, one on the east and the other on the west side of the town. The east Line running near Clifton, by Melkinthorpe and Thrimby, to Shap; and the west Line following the course of the river Lowther, to near the same place.

Either of these Lines will be found very expensive. At Shap a very high country presents itself; the inclinations of a line through this country I have not been able to ascertain, but they must be very objectionable.

A little beyond Shap very difficult ground is approached, where a tunnel would be required, the length of which I could not ascertain, not having the levels of the country.

This tunnel would carry the Line into one of the branches of the river Lune, which falls very rapidly, and in a very serpentine course, and the ground rising to an immense height on each side, immediately from the bed of the river, would compel the Railway to be carried close upon the river side. Numerous crossings of the river would be necessary in order to make the curves passable, and points of the high land running to the river must be cut off. The winding course of the river and the high land abutting upon each side continue to near Sedbergh, where the ground assumes a more favourable character. The valley of the Lune here becomes very beautiful, and is studded with gentlemen's houses and mansions. From Sedbergh to Lancaster the ground is very favourable, but it appears to me impossible to carry the Line in the valley, on account of the numerous residences upon the banks of the stream; and if the valley be not pursued the whole way, the Line must be very expensive in its execution.

The next consideration is the merits and objections of the two routes.

As an act has been obtained for a Railway between Maryport and Carlisle, and plans are deposited in the Parliamentary offices for a Railway between Whitehaven and Maryport, I may suppose that these Lines will be made independently of any Railway from the South to Scotland, and that the local traffic is sufficient to make them pay. I therefore find, that by the Coast Line the number of miles of Railway to make for the purposes of a communication from Lancaster to Carlisle is, as nearly as I can measure from the map, about forty-nine miles and a half. This line would require that the Lancaster and Preston Railway should be deviated for two or three miles in approaching the town of Lancaster, or that two Lines should be made for a short distance at Lancaster. If two Lines are made, this distance would be increased to fifty-one miles and a half.

From Lancaster to Carlisle, by Kirkby Lonsdale and Penrith, would require, from the same measurement, sixty-six miles and a half of Railway, giving a distance of fifteen miles in favour of the West Coast Line.

The distance between Lancaster and Carlisle by the West Coast Line is eighty eight miles and three quarters; and by the Kirkby Lonsdale and Shap Line sixty six miles and a half, leaving in favour of the Shap Line twenty two miles and a quarter.

The next consideration is as to the working of the two Lines. If the Line by Shap Fells be about five hundred feet above the Coast Line, the merits of the two Lines would be nearly equal in point of time in travelling between Lancaster and Carlisle, providing the inclinations are such that the engines can travel upon them with facility.

There is a very serious consideration which has not heretofore been sufficiently regarded by companies projecting Railways over high countries, namely, the great length of the winters, the quantity of snow falling in highlands, and the length of time it remains upon the ground. These considerations, coupled with the effect produced by the ice upon the rails, in retarding the engines, will, in my opinion, be an insurmountable difficulty to the passing of the Shap ridge, especially as the inclinations at the summit must be steep. The snow posts erected on this ridge, to point out to travellers the course of the road when covered with snow, are a sufficient indication of the great severity of the winters. And as this Line would form the western thoroughfare between England and Scotland, it would be of the greatest importance that there should be no impediment which could prevent the engines travelling upon it at all times. My opinion is, that a Line across these hills would be interrupted by the severity of the winters for weeks together.

The Coast Line would be entirely free from this objection, owing to the lowness of its levels, and its proximity to the sea breeze, where neither frost nor snow are ever severe, and where snow almost immediately disappears from the ground.

It may be objected that the sea would occasionally break into the sands enclosed across the Bay, and wash away the Railway; this could not, however, take place if the structure were properly executed.

The Coast Line being almost a dead level, would form the most certain thoroughfare that could possibly be constructed, and might be travelled upon at all times, at almost any velocity, as it would be entirely free from sharp curves, which must be very frequent on the Shap Line.

As regards the local population, the Coast Line has also greatly the advantage, as it affords an immediate communication between the towns of Ulverston, Whitehaven, Workington, and Maryport to the south, and very convenient branches may be made to Kendal, Milnthorp, and Cockermouth; whereas I think the Shap Line only accommodates Kirkby Lonsdale and Penrith.

From the foregoing observations, you will perceive that I am inclined to favour the Coast Line, and I do so from the following considerations:—First, It will be very much cheaper to make, considering the land gained at Morecambe equal in value to the cost of gaining it; secondly, it does not interfere with ornamental property of any description; it accommodates a much larger population; it runs through a country almost perfectly level, and affords communication to many harbours along the coast, which must be of great importance to the country; it is free from objections in winter from the snow and ice; affords easy communication to several towns by branches; and it gives the MOST EXPEDITIOUS, CERTAIN, AND SAFE CONVEYANCE which can be obtained through this country.

It is true that the Shap Line has the advantage in point of distance, but when I take into consideration the difficulty of the country through which it would pass, the expense of construction, and the great height of the summit to be attained, it would be found to take more time in travelling upon it than the Coast Line, and with the other disadvantages it possesses, and feeling NOT THE SLIGHTEST DOUBT of the easy practicability of carrying the line across Morecambe Bay, I have no hesitation in expressing my decided conviction of the superiority of the Coast Line.

It appears to me, that the line of railway through the district I have described would be of such great importance to both England and Scotland, that it is well worthy the attention of Government in giving their assistance and support in its execution.—I am, gentlemen, your most obedient servant,

Alton Grange, Aug. 16, 1837. GEORGE STEPHENSON.

OBSERVATIONS ON MORECAMBE BAY.

The sands in this Bay appear to be composed almost entirely of calcareous matter, washed from the surrounding limestone district, and capable of being formed into the most fertile soil for agriculture. The sea has in many places receded, and left the sand nearly dry at high-water; where this is the case, the land is well grassed over, which I am informed it does very readily, and quite spontaneously; and from the specimens of the quality of land saved from the Bay, which I had an opportunity of seeing adjoining the beach, all doubt was removed from my mind as to the probable fertility of the soil, and its great value and benefit to the country, if it could by any means be preserved from the tide.

I will now give you some idea of the mode which I think ought to be adopted in fencing off the sea. I consider that it would be quite impossible to carry an embankment across these sands in the usual way to keep out the tide; for supposing it to commence on each side, keeping it the required height until the entrance into the Bay was considerably diminished, the efflux and reflux of the rivers and tides would be so great as to make it impossible for any embankment to be made capable of resisting the current.

I would commence by piling entirely across the Bay, at such intervals as I would consider necessary for protecting the foundation of the fence until it was finished. The fence should be commenced on the land side of the piles, taking about a foot in height at one time, across the whole Bay, with blocks of such a size as to withstand the sea. These blocks may easily be procured on both sides of the Bay. By the time one foot in height is carried across, a sufficient deposit on the land side would have taken place to fill up the height of the foot specified.

I would then go on, foot by foot, until the whole was accomplished; and the tide would flow over the fences as at present, until the Bay was filled up beyond the reach of the tides.

The whole of the water coming into the Bay from the rivers in floods, could not have any injurious effect upon the fence, as during the execution of the work the Bay itself would be converted into a lake, and the waters from the rivers would be equally dispersed over the whole, falling in a thin sheet of water over the weir, and would have no tendency to disturb the deposit on the land side of it.

The whole of the matter brought down by the rivers would have sufficient time to deposit itself in the Bay before the water could find its way into the sea, and in a very short time the Bay would fill up to high-water mark. There would also be a quantity of deposit left by each receding tide passing over the weir, until the top of the weir was above the reach of the tides.

I find that in the neighbourhood of Bootle, in Cumberland, the sea is making land for a considerable distance along the coast, without any artificial means. This material is formed from the soil which is brought down into the sea from the river in floods, but is of a very inferior description as compared with the material found in Morecambe Bay.

During the time the work would be going on, the channels of those rivers which now empty themselves into the Bay would be rendered innavigable; but when the work was completed, the rivers would be navigated much more advantageously than at present, for as soon as the Bay was silted up above high water, I would propose that channels for the rivers should be made on each side, with an outlet into the sea by arches; when no more water would flow in by the tide than the channels of the rivers could contain.

These rivers might be of great advantage to the land enclosed, as flood-gates might be put in, so as to allow the river to flow over the land in floods, and lay a fresh deposit on the Bay.

The line I have laid down across the Bay would reclaim about twenty thousand acres of land, but I think that forty thousand acres might easily be reclaimed; however, before I venture a strong opinion upon this point, I should like to have borings made at the place selected for crossing, in order to ascertain the nature of the substratum.

Considering one-half as a fair proportion of the expense of this embankment to be paid by the railway, and the remainder by the proprietors of the Bay, the latter

would be an excellent investment, and it would render the former a cheap work through that district.

It is a generally known fact, that very large tracts of land have been saved from the sea in Holland, and also on the eastern coast of England.

Alton Grange, August 16, 1837. GEORGE STEPHENSON.

GRAND JUNCTION RAILWAY.

On the 17th ult., an official report was made to the proprietors of the result of the first six months' operations. It appears, that during this period the business has been confined exclusively to carrying passengers and parcels; that the gross receipts have been £116,740. 10s. 7d. With respect to the arrivals in general, although it is acknowledged that there has been reason to regret many disappointments arising from various causes, some of which are removed, and others greatly diminished, it is considered on the whole satisfactory. Of 1600 first class trains, 1133 have kept time accurately; 1193 have not exceeded thirty minutes beyond the exact time, and including *all detentions whatever*, the average of the whole is only four hours forty-five minutes, which is considerably less than one half the time formerly occupied in performing the distance. Not a single fatal accident has occurred to any of the 282,202 passengers conveyed by this company since the opening; and in cases of accident, with the description of engine adopted on this line, the risk to passengers is said to be reduced to a degree hardly deserving of consideration. Although the receipts from travelling have declined during the winter quarter, the amount of business in this period has been steady and profitable, and the ratio of decrease is less than might have been expected, from the experience of other railways. The arrangement with the Post office for the conveyance of mails having been found, on trial, not to afford an adequate compensation for the service performed, a new agreement has lately been made, the terms of which increase considerably the revenue from this source. The accounts laid before the meeting exhibited a clear balance of profit to December 31st, 1837, of £56,035. 10s. 10d., which will afford a dividend of £5 per share, leaving a surplus of £1415. The net profit for Sunday travelling amounts to 6s. per share; and the directors recommend to the proprietors, that any shareholder who may refuse to receive it, shall be required to relinquish all claims to it afterwards, in order that it may be appropriated to charitable purposes.

PARLIAMENTARY PROCEEDINGS.

House of Commons.

Jan. 16.—Ribble Navigation.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 16.—Torquay Roads.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 16.—Montgomeryshire Western Branch Canal.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 16.—Brandling Junction Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 16.—Milton next Sittingborne Improvement Bill.—Read 2nd, and committed to Sir Edward Knatchbull and the Kent List.

Jan. 16.—Paington Harbour Bill.—Read 2nd, and committed to Sir John Yarde Buller and the Devon List.

Jan. 23.—Tenby Improvement and Harbour.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 23.—Manchester, Bolton, and Bury Canal, &c.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 23.—Brecon Market.—Report (15th December) from Select Committee on Standing Orders, read; Bill ordered to be brought in by Colonel Wood and Mr. Morgan.

Jan. 23. Private Bills.—Petition of the Chairman of a Meeting of Landholders, Commissioners of Supply, and Justices of the Peace of Aberdeen, for alteration of practice relative to the taking of Evidence upon Private Bills; to lie on the Table.

Jan. 23.—Private Bills. Resolved, "That no Private Bill be read a second time until six days after a Breviate thereof shall have been laid on the table of this House, and have been printed.

Resolved, "That such Breviate shall contain a statement of the object of the Bill, a summary of the proposed Enactments, and shall state any variation from the general Law which will be effected by the Bill.

Resolved, "That Mr Speaker be authorized to give such directions as shall seem to him best for carrying into effect the above Resolutions."

Jan. 25.—Gravesend Pier.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 25.—Eastern Counties Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Jan. 25.—Edinburgh and Glasgow Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

LAW PROCEEDINGS.—ROLLS COURT, JANUARY 13, 1838.

CALVERT *v.* THE LONDON DOCK COMPANY.

The Master of the Rolls gave judgment this morning in the case of Calvert *v.* The London Dock Company. The London Dock Company entered into an agreement with Mr. Streather, the builder, to make a new entrance to the docks, near Shadwell, for which they agreed to pay him £52,000 by instalments, the work being measured monthly, and two-thirds of the amount paid—the other third being retained by the company until the completion of the whole. The company, who had taken securities from certain persons to ensure the contractor's performance of his agreement, advanced to Streather monthly sums of money, far exceeding his claim for work done, without the cognizance of the securities. Streather became a bankrupt, and the Dock Company brought an action at law against his securities for the purpose of compelling them to pay the extra amount of expenditure incurred by them in the completion of the contract, and also the sums advanced beyond those due for the work actually done, and obtained a verdict of one shilling damages. Mr. Calvert and the other security applied to this court, upon the whole merits of the case, for an injunction restraining the company from taking out execution upon the judgment with respect to the costs. His lordship said, that under all the circumstances of the case, he was of opinion that the plaintiffs were entitled to have the injunction made perpetual, and to have the costs of this suit paid to them by the Dock Company.

At the Bucks Quarter Sessions, last week, the Earl of Orkney appealed against the order of the bench of magistrates in petty sessions, who had refused to compel the Great Western Railway Directors to build a larger culvert, or way for a water-course on the Earl's estate in Buckinghamshire, over which the line of railway passes. The counsel for Lord Orkney contended, that the smallness of the channel made by the company obstructed the ordinary flow of water to a mill belonging to his lordship, and contended that the culvert should be widened two feet. Mr. Talbot, for the Company, brought forward evidence denying the obstruction, and proving that Lord Orkney had received the immense remuneration of £300 an acre for his land, which was a full compensation for any trifling inconvenience he might suffer. The bench, after a patient hearing, quashed the appeal.—*Bucks Gazette.*

Compensation.—A jury was called to assess compensation to Mr. Gill, of Newcastle, for a small piece of land belonging to him, which is wanted by the Great Northern Railway Company. Mr. Gill claimed £11,000 as the value of the land, and the Company offered him £1,260. After hearing a great number of witnesses, the jury awarded the sum of £1,280 as a full compensation, being nearly £10,030 less than the claim!—*Tyne Mercury.*

Nuisances.—The Chief Justice of the Common Pleas, in giving judgment on a demurrer to a plea in an action for a nuisance, stated his opinion that every one had the common law right of wholesome air, and a plaintiff could not be deprived of that right because the person causing the nuisance had occupied his premises before the plaintiff came into the neighbourhood. The other judges concurred. The nuisance complained of in this instance consisted in defendant's carrying on the business of a candle-maker; he pleaded that he had carried on his business in the same place for three years, whilst the plaintiff had only recently come to the contiguous premises.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 24TH DECEMBER, 1837, AND THE 25TH JANUARY, 1838, BOTH INCLUSIVE.

William Rutland Pzon, of Cambridge, for "Improvements applicable to Steam Engines."—4th January; 6 months.

Henry William Nunn, of Whippenham, Isle of Wight, Lace Manufacturer, for "Improvements in the manufacture, and in the making or producing of certain descriptions of Lace and other ornamental Fabrics."—4th January; 6 months.

Nathaniel Worsdell, of Crown street, Liverpool, Coach builder, for "Improvements in Apparatus to facilitate the conveyance of Mail Bags and other Parcels on Railways or Roads."—4th January; 6 months.

Bennet Woodcroft, of Mumps, Oldham, Lancaster, Gentleman, for "Improvements in the construction of Looms for weaving various sorts of Cloths, which Looms may be set in motion by any adequate power."—4th January; 6 months.

John Richardson, of Hutton, Yorkshire, for "Certain Improvements in the method of covering Buildings."—4th January; 6 months.

Charles Watt, of Manchester, Lecturer on Chemistry, and Thomas Rainforth Terrutt, of the same place, Merchant for "Certain Improvements in the manufacture of the Oxides of Lead, and also of the Carbonate of Lead."—5th January; 6 months.

William Wells, of Manchester, Machine maker, and Samuel Eccles, of the same place, Merchant, for "Certain Improvements in Power looms, and in Hand-looms, for weaving plain and figured Fabrics."—5th January; 6 months.

Charles Fitton, Woollen Manufacturer, and George Collier, Mechanic, both of Camberworth Hall, near Wakefield, York, for "Improvements in Power Looms."—5th January; 6 months.

John Thornhill, of Ison Green, Nottingham, Lace Maker, for "Improvements in the manufacture of Lace."—5th January; 6 months.

John Edwards, of Lincoln's inn Fields, Pen Maker, for "Improvements in Instruments used in Writing."—5th January; 6 months.

Hugh Ford Bacon, of Fen Drayton, Cambridge, Clerk, for "An improved Apparatus for regulating the flow or supply of Gas through pipes to Gas-burners, with a view to uniformity of supply."—5th January; 6 months.

William Southam, of Ditchford Mills, Nottingham, Miller, for an "Improved Apparatus or Machine for drying Corn and other Grains and Seeds."—5th January 6 months.

Charles Watt, of Manchester, Lecturer on Chemistry, and Thomas Rainforth Terrutt, of the same place, Merchant, for "Certain Improvements in the manufacture of the Hydrate and Carbonate of Soda from the Chloride of Sodium, applicable to the making of Soap, Glass, and other useful purposes."—5th January; 6 months.

Richard Bright, of Bruton Street, Berkeley Square, Lamp Manufacturer, for a "New or Improved Apparatus or contrivance for effecting the more complete combustion of Candles, and superseding the necessity of snuffing"—13th January; 6 months.

Edward Davy, of Fordton near Crediton, Devon, Merchant, for "Improvements in Saddles and Harness for Horses, and in Seats for Carriages."—13th January; 6 months.

Charles Barnard, of Norwich, Ironmonger, for an "Improved Mangle."—13th January, 2 months.

George Chapman, of Whitby, York, Engineer, for "Certain Improvements in Steam-engines."—13th January; 6 months.

Henry Hewitt, of No. 5, Stockwell Common, Surrey, Gent., for a "New or Improved chemical Compound or Medicine, to be used in the form of Pills, for the cure or amelioration of Sciatica, Rheumatism, and Gout, Lumbago, Ague, and other Diseases of a similar nature."—18th January; 6 months.

Julian Augustus Tarner, of No. 2, Henry Street, Liverpool, Architect, for an "Improved Method of propelling Vessels through water."—18th January; 6 months.

Luke Barton, of Arnold, Nottingham, Framesmith, for "Certain Improvements in Machinery for frame-work knitting."—20th January; 6 months.

Frederick Oldfield Ward, of Camberwell, Surrey, Medical Student, for an "Improvement or Improvements in Clothes and other Brushes."—20th January; 6 months.

Ambrose Ador, of Leicester Square, Middlesex, Chemist, for "Certain Improvements in producing or obtaining motive power."—20th January; 6 months.

Herbert George James, of Lower Thames Street, Wine Merchant, for an "Improvement in making Bread, being a communication from a foreigner residing abroad."—23rd January; 6 months.

Thomas Hancock, of Goswell Mews, Middlesex, Patent Water-proof Cloth Manufacturer, for "Improvements in the Method of Manufacturing or preparing Caout-

chouc, either alone or in combination with other substances."—23rd January; 6 months.

Robert Garton, of Beverly, York, Millwright, for "Improvements in Presses." 25th January; 6 months.

Francis Charles Parry, of Brompton, Middlesex, Esq., and Charles de Laveleye, of King's Head Court, London, Engineer, for "Improvements in the Manufacture of Bricks." 25th January; 6 months.

Charles Hancock, of Grosvenor Place, Hyde Park, Middlesex, Animal Painter, for "Certain Improved means of producing figured surfaces, sunk and in relief, and of printing therefrom; and also of Moulding, Stamping, and Embossing."—25th January; 6 months.

STEAM NAVIGATION

The largest steamer in her Majesty's navy is the *Gorgon*, recently built, being of 1,150 tons, builders' measurement. She will carry twenty days coals, one thousand troops, one hundred and fifty crew, with stores and provisions for all for six months. The engines are three hundred and twenty horse power, and the vessel is so constructed, that the steam machinery can scarcely be reached by shot.

Expenses of Steam Boats.—A steam-packet of 100 horse power, equipped as it ought to be, costs about 20,000*l.*; expenditure of fuel, wages, and victualling, about 250*l.* per month; tonnage duty, lights, pilotage, and port charges, 200*l.* per annum; insurance, 100*l.* per month, small repairs and winter expenses, about 500*l.* These items, with the expenses of boiler, which amounts to about 1,500*l.* in the ten years a vessel is calculated to last, and a reserve fund of about 2,000*l.* per annum for the construction of another vessel, makes altogether the sailing expense of such a vessel, about 1,000*l.* per month.—*Hull paper.*

Great Western Steam ship.—The important experiment which this fine vessel is destined to make, will soon be brought to the test. The *Great Western* is now in the Thames, receiving her engines, she will be ready for sea in March, and will take her departure from Bristol for New York early in April.

Another splendid Addition to the Steam vessels of Aberdeen.—We are glad to learn that the Aberdeen and London Steam Navigation Company have purchased the splendid and powerful steam vessel, *Duchess of Sutherland*, of Inverness. She is intended, we believe, for the London passage. The purchase price was 13,500*l.*, which is considered, by those qualified to judge of the value of the vessel, to be much within the mark. The original cost of the *Duchess of Sutherland* was upwards of 18,000*l.*, and having been only little more than a year at sea, she must be little worse of tear and wear. The *Duchess of Sutherland* was purchased first by a company in Inverness, for the Inverness and London trade; built by special contract by Robert Napier of Glasgow, and is considered to be the fastest going steamer from the east coast of Scotland. We had pleasure in adverting, in a late paper, to the very liberal manner in which the Aberdeen Steam Navigation Company have conducted their business; and the purchase of this splendid vessel is an additional proof of the great desire that spirited Company have to give every accommodation to the trade.

The removal of the Peninsular steam packets from Falmouth to Plymouth has caused considerable excitement at the former place. A meeting was held upon the subject last week, when a letter from their representative, the Solicitor General, was read, stating that the Admiralty had acceded to the new arrangement. Fears are there entertained, that this step will be followed by the removal of the West India packets to Plymouth also.

The *Semiramis* steam ship, bound for Bombay, passed this port (Plymouth) on the 5th of December, and put into Falmouth, where she remained a few days, and then proceeded on her voyage, which she expects to accomplish in 70 days, and for which, if performed within the stated time, she will receive a gratuity of 5,000*l.*—*United Service Journal.*

The expense of a steam vessel of 1,000 tons, and 300 horse power, built in London in the cheapest mode, with the most perfect machinery in present use, would be about 35,000*l.*—*Mr. Wm. Morgan's examination on India communication by Steam.*

Great American Steam Ship, Natchez, of 900 tons burthen, which is constructing under the direction of Captain W. W. Story, at the ship yard of Messrs. Rogers, Brown, and R. Colley, south side of the basin, is rapidly advancing to completion. This noble vessel is intended to ply between the cities of New York and Natchez.

American Law against Steam boat Accidents.—A bill has been introduced into the Senate, and committed to a large select committee. The following is a summary of the provisions. It provides, in the first place, that owners of all steam vessels shall register them before October next, and take out a new licence, under a penalty of 500 dollars. District judges of the United States are to appoint, on application of owners or captains, persons who shall inspect the vessels. The certificates are to contain a statement of the age, condition, and time during which the vessels have been running; also the amount of steam they are permitted to carry, and whether the machinery be fit for use and sound. A copy of each certificate to be delivered to the surveyor or collector of the port where application is made for a licence. The inspections are to take place at least once a year, and the boilers to be tested by a hydraulic pump every six months. In cases where boats stop while on a trip, captains are required to keep the machinery going sufficiently to work the pumps for supplying the boiler, and cause the safety valves to be opened so as to keep the steam at the same height as when in progress, under a penalty of 200 dollars for each failure to do so. Boats not exceeding 200 tons are required to carry two yawls, capable of containing twenty persons each, and those exceeding 200 tons to carry four yawls, of the same or greater size, under a penalty of 300 dollars. It is made the duty of every captain to provide his boat with a suction engine and hose, to be kept in good order, and carried during every trip. In ascending and descending rivers, it is made the duty of the master or pilot of the descending boat, to shut off the steam whenever she shall come within half a mile of any boat ascending, and to float up with the current, it being incumbent on the ascending boat to steer clear of the descending one, under pain of being liable for any damage that may occur. Every boat is to be provided with two lights, one three and the other ten feet above the upper deck, during all hours between sunset and sunrise. The penalties accruing under the act are to be recoverable in any District or Circuit Court of the district where the offence may have been committed, or the owner or captain may reside, one-half to the use of the informer, the other to the United States. Every captain, engineer, pilot, or other person employed in navigating any steam-boat, by whom misconduct, negligence, or inattention to his or their respective duties, the life or lives of any person or persons shall be destroyed, to be deemed guilty of manslaughter.

STEAM NAVIGATION IN TURKEY.

Constantinople, 24th Nov., 1837.

Comparatively speaking, until very recently, steam-vessels remained almost unknown in this country, although its waters and peculiar currents are so well adapted to develope the advantages of steam power. Within a very short period, however, a considerable number of steamers now frequent this port, and they are constantly increasing. The French Government steam-packets are appointed to arrive here every ten days from Marseilles, touching at Leghorn, Civita Vecchia, Malta, Syra, and Smyrna, and returning by the same route. They ought to perform the voyage between Marseilles and Constantinople in 13 days, but as yet they have not been very regular, and several accidents have happened.

The Trieste Lloyd's Commercial Company have established a line of steamers from that port to Constantinople twice a month, touching at Arrocona, Corfu, Patras, and Athens, returning by the same route. Another Austrian company, established at Vienna, make Constantinople their head-quarters, and possess several fine steamers, one of which they run between this port and Galatz; another to and from Trebizond; another to and from Smyrna; and a fourth to and from Salonica. The Russians have a steamer between this and Odessa. At present there are only three English steam vessels stationed here, viz., the Crescent, trading between Constantinople and Trebizond; the Essex, employed as a towing-vessel on the Bosphorus; and the Levant, formerly on the Smyrna station, but now employed on any service that may offer.* The Sultan does not at present possess a single steam vessel, but jealous possibly of his vassal, the Viceroy of Egypt's fine steam frigate, the Nile, which was here some time ago, he is now building two large ones in the arsenal, for which the engines are ordered in England. Twelve months ago the Porte possessed two old steamers, sent from England for sale on speculation three or four years previously, but as the Turks shockingly mismanaged and wore them out, the Sultan adopted a singular expedient of getting rid of them. He was graciously pleased to recommend (order) his Rayah, or Greek subjects, to form a company for steam navigation, to supersede the Ghiour, or Infidel companies; and in order that his subjects might commence operations without any delay, he liberally deprived his own navy of the only two steamers the government possessed, by selling them to his Greek subjects, himself fixing their price at 8,000*l.* for one, and 4,000*l.* for the other. In vain did the poor Greeks venture to urge that they knew nothing about steam vessels, and did not wish to embark in such an undertaking; remonstrate they dare not, and they bowed to the Sultan's decision. The company was formed—the purchase money (fixed by the seller) was produced, and the steamers were made over to the company. The result was as quick as it was disastrous. The very first voyage attempted by the largest steamer to Smyrna she was run on shore, and her boiler burst in attempting to get her off. The smaller one was then dispatched to tow the other back to Constantinople, where she has remained ever since perfectly useless. The next voyage attempted by the smaller steamer she was run on shore, and totally lost at the Dardanelles, with much specie on board. The greatest difficulty which steam navigation in this country has to contend with, is procuring respectable and efficient engineers, so many of whom unfortunately give way to excessive drinking, or prove to be ignorant of their duties. Another drawback is, the almost impossibility of getting any serious accident to the machinery repaired here; but the oldest established Austrian company have wisely guarded against this, by having formed their own factory at Smyrna, where they repair or refit their vessels. The average price of coals laid down here from England is 40s. per ton.—*United Service Gazette.*

PROGRESS OF RAILWAYS.

Brighton Railway.—There is every prospect of a commencement of this long disputed railway: the shares during the last month have risen from a nominal price to a premium, notwithstanding a call of 3*l.* per share has been made. A meeting of the shareholders was held on the 18th ultimo, when the Report of the Directors was unanimously adopted.

The Central Kentish Railway.—We were much surprised to hear that a line of country could be found through Kent for a railway, which can be constructed without a single tunnel, or inclination exceeding 1 in 306, and that for a very short distance; if this be the case, it will be a very formidable rival to the South-eastern Railway.

The London and Southampton Railway is rapidly proceeding towards completion, the line from the terminus at Nine Elms, through Kingston, nearly to Guildford, will be open to the public in May next, and from Winton to Southampton in the course of next summer. Contracts have been entered into for the buildings to be erected at the terminus at Nine Elms, under the direction of Mr. Tite, architect.

Lancaster and Preston Junction Railway.—Active operations are about to be commenced on this line, which is rather more than 20 miles in length; the works are to be divided into four contracts, to be executed under the direction of Joseph Locke, Esq.

Bolton and Preston Railway.—So far from the land between the surface, and through which it was intended to make a tunnel about 300 yards long for this line of railway to pass on the north of Chorley, being favourable for the purpose, it turns out to be all quicksand and filled with water. It is yet hoped that by taking it a little more to the north, a more favourable result may be the consequence.—*Preston Observer.*

North Union Railway Bridge.—Notwithstanding the frequent and harassing floods with which the contractors have had to contend, the second arch, from the north side of this magnificent structure, has been completed, and much progress has been made with the centres for the three remaining arches. The stone work is massy, and well put together, and its magnitude, beauty, and solidity, excite the admiration of all who see it.—*Ib.*

Newcastle on Tyne and North Shields Railway.—The commissioners under the North Shields Town Improvement Act have come to the determination of opposing, by every means in their power, the passing of the act for which the company have given notice of their intention to apply to Parliament during the present session, to enable them to extend the railway from the west end of Wellington Street, North Shields, to the village of Tynemouth. They say, that they conceive such extension would be "not only a most serious nuisance, obstruction, disturbance, and annoy-

* A new steam company has just been formed by the saraffs, or Armenian banker of Constantinople.

ance to the town generally, but entirely destructive of the value of property in the immediate locality of the proposed line." They have declared their intention to oppose the bill by counsel in Parliament.

There were no fewer than 21 candidates for the office of Resident Engineer to the Corporation of Newcastle, several of whom have very excellent testimonials as to character and ability.—*Tyne Mercury.*

A handsome locomotive engine, drawn by a team of sixteen horses, passed through Newcastle, on its way to the Stanhope and Tyne Railroad, being the second within these few weeks supplied from the Bedlington Iron Company. The last is a most powerful engine, having six wheels, all coupled, and calculated to draw a load of three hundred tons. The construction and execution of these engines reflect the greatest credit on the manufacturers, in compliment to whom the Railroad Company have named the most powerful "Michael Longridge," after one of the enterprising partners in the Bedlington Iron Company.—*Gateshead Observer.*

There are now at work on the Stanhope and Tyne Railway three handsome and powerful locomotive engines, one of them calculated to draw the enormous weight of 300 tons. This latter engine was manufactured at the Bedlington Iron Works.—*Sunderland Beacon.*

The Great North of England Railway.—This undertaking, we are glad to hear, is making considerable progress. The directors have decided in favour of the plan of Mr. John Green, architect, of this town, for the bridge across the river Ouse, near York. It is to be commenced almost immediately.

Proposed Railway from Gateshead to Green Court.—The extraordinary project of making a railway from Gateshead to Green Court, Newgate Street, in this town, is again revived. An application is to be made to Parliament during the present session for an act to empower the carrying of the work into execution. It is intended, it seems, to cross a public road called the Half Moon Lane, in Gateshead, on the level, but what other course it is to take we know not.

The Preston Railway.—We are informed that the Preston and Wyre Company mean to run steamers, drawing little water, from the Wyre to Rampside, and at the same time to make an economical railway from the latter place to Kirby Ireleth, to meet the coast railway, when made to that point—so that the great line may be used whilst the embanking of Lancaster sands, and the cutting through Furness, are going on.—*Whitehaven Herald.*

Aylesbury Railway.—A special general meeting of the shareholders was held at Aylesbury on the 20th Dec., for the purpose of considering an arrangement proposed with the London and Birmingham Company, as to the future occupation and loan of the Aylesbury Line of Railway. The secretary read a letter from the London and Birmingham Railway Company, offering to make an arrangement with the Aylesbury Company for a lease of their line of railway by the London and Birmingham Company, at a rental of 2,500*l.* a year for five years. The chairman having briefly stated the objects of the meeting, and several of the shareholders having expressed concurrence in the proposed arrangement, a resolution was unanimously carried, empowering and recommending the directors to accept the offer of the London and Birmingham Company.—*Aylesbury News.*

Branch Railway to Oldham.—An opinion appears to be gaining ground, that the directors or shareholders of the Manchester and Leeds Railway Company have an intention to construct a branch from their main line near Foxdenton, in Chaderton, to the westerly side of the town of Oldham. Surveys and levels have been recently taken of the country between Oldham and the main line.—*Liverpool Journal.*

Hayle.—The Hayle Railway is so far completed as to enable the company to send team waggons to the different wharfs for the conveyance of coal, &c., to the mines.—*Cornubian.*

Railway Collision.—On Friday se'nnight, a serious accident happened on the Grand Junction Railway, near Stafford. The Caliban, a spare engine, stationed at Stafford, in case of need, was passing to and fro, under the direction of the fireman only, the engineer not being with it. It was proceeding towards Penkridge, when the mixed train which leaves Birmingham at half past four was observed on the same line of rails. It appears that the steam of both engines was instantly turned off, the alarm whistle sounded by both, but they were too near each other for the collision to be avoided; and between 200 and 300 yards from the Stafford Station house they came into contact, with a tremendous crash. Providentially there was a luggage lorry and two empty horse boxes in the train between the engine and carriages for passengers, one of the horse-boxes was split in two, the lorry and the other horse-box was much injured, and the front of the first passenger carriage was completely stove in. By the violence of the concussion the Caliban became disentangled from its tender, which was thrown on the rails, and the fireman jerked from the engine into the tender, and the engine, left without a conductor, set off in the opposite direction, towards Liverpool, at a terrific speed!—This engine came to a stand still about ten miles off, the steam being exhausted; in its ungovernable course no accident occurred. The passengers in the train suffered no injury beyond a few slight contusions; but the guard, who was seated on the first carriage, sustained a compound fracture of the left leg and several bruises; and the engineman of the Caliban was also seriously hurt.—*Suffolk Advertiser.*

Manchester, Bolton, and Bury Canal and Railway. An engine and a carriage passed over about six miles of this railway, from Manchester towards Bolton, with a party of the directors, to try the engines and carriages over the rails, part of which are laid on timber (*Kyanized*), and part on stone. The result was satisfactory, as far as it went. A decided preference was manifested in favour of that part laid on timber, for softness of sound and smoothness of motion, over that laid on stone, where both sound and motion were, in some degree, more rigid, but not to the extent found on rails laid on stone-sleepers in the ordinary way. On this railway the rails are laid so as to maintain an uniform bearing, their whole length being on a continuous bed of stone or timber, to which they are, in both instances, firmly secured. The engines at present on the line were made by Mr. Edward Bury, of this town, and are fine specimens of workmanship. The carriages are somewhat similar to the first-class carriages on the Liverpool and Manchester Railway, as regards the body; but the under frame differs, being fitted with Bergin's patent spiral spring buffers at each corner, and have, in addition, a spiral spring at each end, for drawing so that when the carriages are put into motion and brought to rest, all unpleasant jerking and jolting are obviated.—*Liverpool Albion.*

Hull and Selby Railway.—The directors of this company contracted for the formation of two portions of the line, for which tenders were advertised; the Hessle contract, commencing on the l ts Mr. Atkinson's property, at Dairycoates, near this town, and terminating at Melt n, a distance of about seven miles; and the Howden contract, commencing at the western extremity of the embankment, near to the Market Weighton Canal, and terminating at the river Derwent, near Wressel Castle, a length of about nine miles. The contractors, in both cases, have engaged to commence the works without delay, and every exertion will be used to complete them at the earliest period possible. The foundations of the bridge over the Ouse, at Selby, are in progress, as are the castings for the iron-work of that bridge, and the iron bridge over the Market Weighton Canal: nearly 200 men are now employed at the embankment adjoining the latter, and the foundations of the bridge over it. The directors of the Manchester and Leeds, the York and North Midland, the North Midland and the Midland Counties Railways, are using every exertion to complete their respective undertakings; and as the Hull and Selby Railway will communicate with them, and through their medium with Liverpool, Manchester, Leeds, Birmingham, London, and almost every part of the kingdom where railways are formed or in progress, the advantages which the town of Hull, and the proprietors of the Hull and Selby Railway will derive from the early completion of the work, must be apparent; and we most sincerely congratulate our townsmen, and the parties more immediately interested on the prospect before them, as we anticipate a very favourable report being presented to them by the directors at the General Meeting, which is to be held in February.—*Hull Observer.*

Leeds and Selby Railway.—Within the last few weeks, a new engine, called the Hawke, has been put upon the line. It possesses great strength, and has the advantage of superior steadiness, by the addition of two small wheels to the other four It is a very fine, swift, and powerful engine, and was made by Messrs. Fenton Murray, and Co., of this town.—*Leeds Mercury.*

RAILWAYS IN SCOTLAND.—*The Dundee and Arbroath Railway.*—An act of Parliament was obtained in 1836 for the formation of this railway, which is considerably advanced, and will be completed in 1838. Its length will be nearly 16¾ miles, and the capital required 99,844*l.*—*The Glasgow, Paisley, and Greenock Railway,* for the formation of which an act was passed in 1837—commencing from the south end of Glasgow Bridge, it will proceed to Paisley, and running nearly parallel to the Clyde, with a branch to Port Glasgow, the line will terminate at Greenock, near the harbour. The estimated expense is 393,000*l.*—*The Glasgow, Paisley, Kilmarnock, and Ayr Railway.*—The line from Glasgow to Paisley is intended to be common to, and to be executed at, the joint expense of the Glasgow and Greenock, and Glasgow and Ayr Railway Companies. Near Daltry it will separate into two branches—one running direct to Kilmarnock, and the other passing by Kilwinning, where it joins the Ardrossan Railway—Irvine, where it communicates with the town and harbour—Troon, joining the Kilmarnock and Troon Railway, and terminating on the quay at Ayr. An act was obtained for this railway in 1837. The estimated expense is 659,000*l.*—*Oliver and Boyd's Edinburgh Almanac.*

Glasgow and Ayr Railway. A railway is about to be formed between Glasgow, Kilmarnock, and Ayr, which will materially increase the facilities of travelling between Glasgow and the north of Ireland. When this railway is opened from Glasgow to Ardrossan, or Troon, steamers will, very likely, be despatched from one of these harbours to Liverpool, Dublin, Belfast, and the north of Ireland, Campbelton, &c., as, by going in this way to these places, there will be about 60 miles of water travelling cut off from the present route, while there will be substituted 30 miles of railway, with such favourable levels, that the journey upon it will easily be performed in an hour.—*Northern Whig.*

Glasgow, Paisley, and Greenock Railway.—The directors have come to the resolution of commencing operations on portions of the road between Paisley and Port-Glasgow, and Port Glasgow and Greenock, and have given orders for the immediate preparation of the plans and specifications for the contracts.

GREAT WESTERN RAILWAY.

It is with the greatest satisfaction we are able to announce, that a full trial was made during the whole of Wednesday, in running the engines on two or three miles of this line near West Drayton, between London and Maidenhead. The object of the trial was to prove the rails, and *most satisfactory was the result*, both as to the increased width of gauge and the use of continuous bearers of Kyanized wood confined by piles, on which plan the line is constructed. An engine with eight feet drawing wheels, made by Messrs. Tayleur and Co., of Warrington, weight twenty-three tons, with the tender, water, coke, &c., and another engine made by Messrs. Mather and Dixon, of Liverpool, weight about nineteen tons, with the tender, &c., ran the whole day without producing the slightest vibration, either in the rails or the wood under them. The rails are in fact so beautifully firm, smooth, and true, that the engine glided over them more like a shuttle through a loom, or an arrow out of a bow, than like the effect on any previous railway, there is, literally, no noise—no apparent effort—nor can there ever be discovered any difference between the centre and the joint in the rails. A maximum speed was not attempted, as on so short a piece the momentum would be no sooner attained than it would require to be lowered in preparation for stopping the engine. A speed of forty-five to fifty miles per hour was attained, and when the engines are run, as they will be either next or the following week, on an eight or ten mile length, there is no doubt they will as easily run at a very much greater speed.—*Bristol Journal.*

FOREIGN RAILWAYS.

Milan, Dec. 19.—Three railways are about to be constructed in this city, viz., to Como, to Monza, and Venice. That to Como will be commenced immediately, the Austrian Government having already granted a patent for it to MM. Bruschetti and Volta, engineers of Milan. M. Bruschetti, well known in Italy as the author of two admirable works on the navigable canals and irrigation of Lombardy, the only books which contain a complete history of the progress of the arts of irrigation and internal navigation in that part of Europe, will shortly visit England for the purpose of examining the railways in that country, and of purchasing the rails and locomotive engines necessary for those proposed in the Austro Italic States.—*Morning Post.*

Railway to Versailles.—It is said that the project of a railway on the Rive Gauche to Versailles will be abandoned, and that the shareholders have come to an arrangement with those of the right bank. This is possible, but I do not believe it; for the parties have deposited with the Government one million and a half of francs, which they must forfeit if their railway be not complete within two years.—*Globe.*

French Railroads.—The Railroad Commission in Paris is making great progress in its labours. It has decided that the three lines to be first attended to, and to be executed by the Government, should be—1st, The line from Paris to Brussels; 2nd, From Paris to Orleans; and the 3rd, From Lyons to Marseilles. Besides these to be executed by the Government, it proposes that the road from Paris to Rouen, and the branch from Amiens to Calais and Boulogne, and from Basle to Strasbourg,

should be executed by railroad companies, either now existing, or which may be created. All branches and isolated lines it also thinks most desirable to reserve for the execution of companies.—*Atlas.*

Railway from Strasbourg to Basle.—A question has arisen to which country (France or Germany) the right belongs, to form the railroad between these two cities, or whether it shall be formed upon the right or left bank of the Rhine; the line as projected by MM. Kœchlin is 115 miles in length, and will connect six populous manufacturing towns, each of which contains upwards of 13,000 inhabitants, to whose manufacturing wants in the transport of merchandise and materials, the enterprise cannot fail to be extensively useful. The anxiety of the French party is at the present moment more excited from the circumstance of the Grand Duke having recommended the German Diet to take into its consideration on the 10th February, the propriety of forming the line on the German side, which, if resolved upon and commenced before the French project, will settle the question in favour of the German line.

Belgium and German Railway.—It is in contemplation to form a railway from Antwerp to Eberfeld, Venloo, and Dusseldorf; the line of country has been surveyed and found to be particularly favourable, and likely to be executed at a very cheap rate. A company is to be formed in Belgium for carrying the railway into effect from Antwerp to Venloo, and another company in Germany for the remainder from Venloo to Dusseldorf, or a united company of the two countries will be formed for carrying the whole into effect at once. It offers immense advantages to Antwerp, and will open a new port to the best part of Germany; it will also be driving the first portion of a line of railway into the very heart of Europe, which will some day be continued to Westphalia, Saxony, Brandenburgh, and Berlin; whilst the railway of Cologne will traverse the Upper Rhine, Franconia, and Bavaria, to the borders of the Austrian capital; the Belgic line will communicate by the Oder with the Baltic, and at the same time by the Danube with the Mediterranean.

AMERICAN RAILWAYS.

Cuba.—The first part of the railway from Havana was opened for passengers on the 10th of Nov. last. The length of the railway from Havana to the terminus at the town of Guines is forty six miles, of which sixteen miles and a half are now open. The road passes through the populous and most important part of the country for passengers, and the great traffic with Havana; the remainder of the line will soon be opened, a great part of the permanent rails being laid down. The population of Havana and neighbourhood exceeds 200,000, and of the several intermediate stations and Guines, 90,000. It is calculated that this road will form a most important source of income, and produce a very favourable change in the agriculture and industry of the island. The great facility of communication which the railroad will afford to passengers, and the saving of time and expense for the conveyance of merchandise, is immense, and can only be fully understood and appreciated by those well acquainted with the country, where there exists no internal navigation, or roads and means of conveyance calculated for these objects, as in Europe.

Auburn and Rochester Railroad. Robert Hingham, Esq., engineer of the Company, has made a Report to the directors, from which we glean the following items. The route estimated upon, commences at the termination of the Auburn and Syracuse Railroad, and passes through Seneca Falls, Waterloo, Geneva, Vienna, Canandiagua, and Victor, extending to a point on the west side of the Genessee River, in the central part of the village of Rochester, where the Tonawanda Railroad can be connected with it. The distance from the village o Auburn to the city of Rochester, by this route, will be 78½ miles; and the road can be constructed without having any grade to exceed 28 feet, ascent or descent, per mile, and that without any very deep cuttings on the summits, or high embankments in the valleys. The estimated cost of the road, graded for a double track, and a single track laid, is 1,091,376.72 dollars, or 14,030.27 dollars per mile For a double track complete, 1,441,398.17 dollars, or 18,390.97 dollars per mile. The revenue likely to accrue from the road is estimated at 361,517.50 dollars per annum; of which 268,368.50 dollars is for the transportation of passengers, and the remainder for that of freight. As the road is of about the same extent as that of the Utica and Schenectady Railroad, the engineer estimates the yearly expenditures at about the same sum, which he puts down at 90,000 dollars; which, being deducted from the estimated revenue, leaves a net profit of 271,517.50 dollars, or nearly 19 per cent per annum on the estimated cost of the road for a double track completed.—*New York Advertiser.*

ENGINEERING WORKS.

Ulster Canal.—This vast work, which ultimately will connect the two great inland waters of the Lough Neagh and Lough Earne, has been completed from the town of Charlemont to the town of Monaghan, a distance of twenty-six miles; and is opened for the purpose of trade. Two of the canal boats, laden with coal, were on the day of opening taken into the lock at Charlemont from the river Blackwater, and from thence despatched, the one to sell her cargo at Caledon, and the other at Monaghan; at each of which towns they respectively arrived without meeting any obstruction or hindrance in the navigation.—*Dublin paper.*

Caledonian Canal.—Part of the side wall of the lower lock at Fort Augustus, below the surface of the water, has unfortunately fallen in. This will occasion a temporary interruption of the navigation for vessels of burden. The Staffa steamer got through the last trip with some little difficulty, but we should fear the larger Glasgow steamers can hardly pass. Several large vessels happened inopportunely to have reached Fort Augustus about the time of the accident, by which they are stopped in their progress. It is the intention, we believe, to fill up the breach in the mean time with bags of sand and earth, till the season admits of a thorough repair.—*Inverness Herald.*

The Dudley Canal Company are constructing a large reservoir at Netherton, near Dudley, which will cover an area of 11 acres clear of the embankments, having a regular depth of 55 feet excepting the slopes, and is calculated to hold 6000 locks of water. The works are contracted for by Mr. Oakes, of Derby, according to the plans and under the superintendence of W. Richardson, Esq., engineer, of Dudley, and are engaged to be completed by the close of the present year.

There are building at Cumberland and on the Weir no fewer than ninety-six ships, some of them of a very large tonnage; and eight have been launched within these few days.—*Cumberland Pacquet.*

NEW CHURCHES.

Glamorganshire.—A new Church is in the course of erection at Newbridge, in this county, where, within the last four or five years, several iron and tin works of the largest size have been established, and from which cause the population has increased four or five fold. It is calculated to hold 850 persons, of which four-fifths are in free seats. It is in the Norman style, with a square tower situated at the angle of the building 80 feet high; its length is 80 feet, its width 40 feet, and is built of a stone raised in a field immediately adjoining, of a grey colour; its texture is exceedingly firm, and its colour forms a very pleasing contrast to the Bath stone, of which the door and window jambs, cornice, clock faces, &c., are constructed. The contract is under £2000. The architect is J. H. Wyatt, Esq.

Brecon. It is in contemplation to rebuild the body of St. Mary's Church, in the town of Brecon, the tower of which is a fine specimen of late Gothic architecture. The design, which is calculated to hold 1,400 persons, has been prepared by J. H. Wyatt, Esq., and is estimated at £4,500, including the necessary reparation of the tower.

Shrewsbury.—The Rev. Richard Scott, who enlarged five of the churches at Shrewsbury, has fitted up, at his own expense, the altarpieces of St. Giles and St. George, and presented to the parishes of St. Chad and the Holy Trinity magnificent silver communion services.

Glasgow.—We feel sincere pleasure in being able to announce, that the new Church at Camlachie is in such a forward state of progress, that, weather permitting, the neat spire with which it is surmounted will be finished in a few days; that Chalmers' Church, which is proceeding with unusual expedition, is ready to receive the roof; that Brownfield Church, Anderston, is already roofed; that the foundation of Wellpark Church, foot of Drygate, has been commenced; that Hutchesontown Church has been contracted for, and will be begun immediately; and that arrangements are in progress for the erection of Martyrs' Church, near the martyrs' stone, at St. Rollox, which will be proceeded with early in the ensuing year. These are pleasing facts, which we hope will encourage the friends of the Church in Glasgow and throughout the country to redoubled exertions. If the Christian public are equally liberal in their contributions next year, and we are persuaded nobody is the poorer for the money contributed to these erections, we hope to be able to present our readers with as gratifying a catalogue of new churches this time twelvemonth. If permanent good is to be accomplished, it must be sustained by persevering efforts. To supply the wants of an increasing population, we require five or six churches a year, independently of the best exertions of the Dissenters. There is room enough for both Churchmen and Dissenters to do their utmost, with the moral certainty, that without assistance from Government, the great object in view will never be fully attained.—*Guardian.*

Yorkshire.—Earl Fitzwilliam, says the *Sheffield Independent*, is at the present moment most liberally assisting in the building and enlarging no less than six churches in this neighbourhood, viz., a subscription of £500 towards the erection of a church at Thorpe; a liberal sum for a new church at Kimberworth; £500 in aid of the rebuilding of Rawmarsh church; and the entire cost of enlarging the churches of Tinsley, Wentworth, and Tankersley, for the accommodation of the poor in their respective parishes. In addition to this munificence towards the church, we may add, that within the last few years his lordship and his revered and venerable father have expended many thousands of pounds in the erection of the churches of Swinton, Hoyland, and Greasbrough.

Wiltshire. A Chapel has just been built at Whitley, in the parish of Melksham, under the superintendence of J. H. Wyatt, Esq.; it is of the pointed or early English character, capable of accommodating 550 persons, and the cost will not exceed £1,600 in its erection.

Middlesex.—The Metropolitan Church Building Committee have decided on building a new church in the Tenter Ground, Goodman's Fields, the working drawings for which are being prepared by J. H. Wyatt, Esq., who has been appointed the architect. It will accommodate about 1,200 persons, according to the sizes of seats adopted by the Church Building Commissioners; but not more than 1,080, according to the increased size of pews and free-seats decided upon by the Committee. It comprises a tower and spire, 100 feet high, and is estimated at 3,800*l.*

Warwickshire. Competition drawings were sent on the 15th ultimo for a church to be built at Oldbury, near Birmingham. The church is to accommodate 1,500 persons, and to have a tower; the amount limited to 4,000*l.*!! to include the architect's commission and clerk of the works' salary. The instructions are, that the church is to be of a plain character; and if the estimate should not come to that amount, the church is to be enlarged.

Shoreditch.—A new Church is to be built in this parish, under the direction of Mr. Vulliamy.

PUBLIC IMPROVEMENTS AND BUILDINGS.

Glamorganshire.—A Public Market House has just been erected at Merthyr Tydvil, in this county, by J. H. Wyatt, Esq., Architect, which occupies a site of 250 feet by 200 feet, and comprises within its walls, 112 butchers' and fishmongers' shops; 87 standings for poultry, eggs, &c; 200 stalls for fruit and vegetables; and 76 stalls for hawkers. There is a fountain and reservoir for water in the centre; and two cart gangways running through the Market, which gives an easy access for heavy goods to all parts. There is an office for the clerk of the market, and a weighing-room, with other conveniences. It is surrounded by four streets, and is approached by twenty archways. The character of the architecture is Italian, having an ornamental clock-tower. It is built of a hard grey stone; the door jambs, archivolts, cornices, and other external moulded work, are of Bath stone. The cost does not exceed £7,000. Slaughter-houses, in connexion with this Market, are being built, at a further expense of £1,000.

Breconshire.—A new Market Place and Slaughter houses are about being erected at Brecon, by the corporation of that town, from the design of J. H. Wyatt, Esq., the estimate for which is £3,000. The corporation have purchased more than sufficient ground for their market with a view to widen Castle Street, the remainder of which will be let on building leases.

Montrose.—*New Infirmary.*—The managers of this institution have now made choice of an elegant design for the building which they are to erect on the Castle Hill. The design is by Mr. James Collie, architect, Glasgow, to whom the premium of twenty guineas has been awarded. We understand it is the intention of the managers to proceed, with all despatch, in the erection of the structure.

Five Monuments to the memory of the late much-regretted general, the Duke of Gordon, are erecting in the counties of Aberdeen and Banffshire.

Monmouthshire.—The Guardians of the "Newport" Union are building a workhouse on Stow Hill, to contain 800 paupers. It is built of stone, raised on the site. The estimate is 3,900*l.*

Hull.—A club house is about to be established in Hull, under the title of the "Union Club," similar to the London club houses. It is to be formed of gentlemen of all parties, and politics are to be excluded.

Westminster Cemetery.—The ground (about 40 acres) intended for the Cemetery is situated on the east side of Kensington canal, between the Fulham and Brompton roads, which will, early in the ensuing spring, be laid out as an extensive ornamental parterre, surrounded with catacombs and a terrace. A church, in the early English style, is to be erected at the north end. Stephen Geary, Esq., is the architect.

Botanical and Zoological Gardens are about to be formed at Leeds and Newcastle.

Subscriptions are on foot for erecting a Public Monument to the memory of the Protestant Martyrs of England, in the London Cemetery, at Highgate. A more suitable spot could not have been chosen: it is the most elevated round the metropolis, and remarkable in history, being the very place where the conspiracy was concocted, on the 5th of November, 1605, for the destruction of both Houses of Parliament: the spot to this day is known by the name of Traitors' Hill. We trust that the design will be similar to some of the crosses in the pointed English style of the fourteenth century.

FOREIGN INTELLIGENCE.

Havre, Jan. 2.—Mr Bellouin, one of the proprietors of the grant for using the American Patent Hydraulic Dry Dock, has been at Havre, to consider of the best means to be employed for establishing the Patent Dry Dock in this port. M. Legrand, general director of bridges and roads, and M. Frissard, chief engineer of the ports, have taken considerable interest to demonstrate the advantages of this ingenious machinery to the port of Havre, which will be improved by means at once so simple and so powerful as to lay up dry, ships of the greatest tonnage. M Bellouin is now adopting proceedings for the purpose of obtaining from Government its consent for forming a Company, to establish, at their own expense, and at a convenient spot, the dry dock, which will supersede the dry creeks that were proposed.

New York Water Works.—There are more than twenty miles of this work under contract and in progress. About twelve hundred men are employed on the various parts of the line, and the expenditure for the month of November alone amounted to nearly 45,000 dollars. Of the aqueduct, about 2,500 feet are completed. About three thousand labourers will be employed on the work in the spring.—*Charleston Mercury.*

Croton Water Works.—On Friday last we made a visit to the Croton Water Works, and passed along the line, north of this place, to its junction with the Croton. The contract for building the dam has just been taken; much of the foundation wall will be built this fall, and the materials collected during the winter for its completion the next season. Several sections that we visited are already far advanced, and parts of some entirely completed, with the exception of the outside embankment.

Several extensive tunnels are now under way, in some of which the blasters are already nearly 200 feet beyond daylight.

It is surprising to observe how beauty and solidity are blended in the construction of this stupendous work. Having had much acquaintance with the business of brick and stone masonry, we can say that better or finer cannot be found in the United States than that now being done on the Croton works.

Few, very few, have an adequate idea of the magnitude of this undertaking. A slight one may be formed by a part of a single section which we examined. At this point it passes a deep ravine; here a wall some fifteen feet thick is carried to nearly thirty feet in height, composed first of layers of large flat stone compactly laid, and then a course of stone pounded to the size of pebbles, so that every crack and crevice are filled up; and upon this a thick laying of stone and water cement, that the whole may become as one solid rock.

It will remain an enduring monument to the enterprise and perseverance of the city of New York, and will rank among the most important works the hand of man has ever accomplished.—*Hudson River Chronicle.*

St. Isaac's Church, at St. Petersburgh, is probably the largest building which modern Europe has seen arise, and will long continue an object of wonder to strangers. It is a mass of architecture 340 English feet in height, entirely of marble and metal, decorated outside with 112 columns of red granite, each consisting only of one piece. The marble dome, surrounded by a colonnade, is 109 feet in diameter, and around it rise four steeples intended for the reception of bells. The whole forms a monument to be compared only with the colossal works of India and Egypt. The church is to be finished in 1841. The twenty-four columns which support the dome are each forty-two feet high, of a single piece, and from the same quarries in Finland which furnished the Alexander column; each weighs 200,000 lbs. The machinery by which they were raised to a height of 200 feet and fixed in their respective places, is in itself deserving of wonder and admiration.

Burning of a Church at Ghent.—A letter from a gentleman residing at Ghent contains the following intelligence:—

"Saturday, January 20, two o'clock in the afternoon.

"A frightful fire has just reduced to ashes the enclosure of the church of the Augustines, and the church itself. It broke out at about three o'clock in the morning in a manufactory that formed one wing of the building, which is still burning. Thence the flames extended to the church, an edifice of considerable beauty, which is completely destroyed. It contained some valuable pictures by De Croyer and De Reyschoet, which are lost, as well as the very remarkable object known by the name of 'The Pulpit of Truth.' The tower of the church fell this morning about seven o'clock. Nothing remains but the walls. That part of the building which was occupied by the monks has been wholly burned, with the library, of which I saw some of the books thrown up into the air. The library of M. Lammens must have suffered much. At this moment attempts are making to save part of the property, by conveying it to the neighbouring houses. The crowd has been so great that I have not been able to get near enough to ascertain how much has been rescued from the flames. Happily the building was vaulted. The whole, however, is at present in a blaze, and I do not know if there will be time to secure all the books."

Singapore New Church.—The style of the building is Roman. The sea-front consists of a pediment, carried out on six Doric columns, the enclosed space being partly occupied by the chancel, which stands out in a semicircular form at this extremity; a cross standing in strong relief against the tympanum of the pediment. The land-front is the same; and includes a portico in which two carriages can pass each other. The sides of the building are adorned with pilasters, surmounted by a ballustrade; a spacious verandah, of the same dimensions as the portico of the land-front, occupies both sides; so that every side of the building can be entered under a complete and agreeable shelter. The interior form of the church composes three parts of a circle, which is cut off at the end nearest the chancel. The pulpit stands under a lofty arch, which stretches the whole width of the chancel; and the walls at either side are ornamented with Ionic pilasters, with intervening spaces adapted for mural monuments. The roof is supported by Ionic columns, which rest on pedestals, rising from the floor of the building to the level of the galleries: the latter are built over the space which encloses the verandah and portico below, and are twenty-two feet in width. The interior is graceful and pleasing; it is effectually shaded, and well ventilated, and the accents from the pulpit are heard with ease and distinctness throughout the building. The exterior is not very imposing; the lowness of the building gives it a less striking character than it would possess if raised on a more elevated basement; but the funds, at the command of the architect, it is understood, were insufficient.—*Singapore Free Press.*

LOUVRE.

The re-opening of the Galleries of the Louvre, together with the Naval Museum, hitherto accessible only to the privileged, the Spanish Museum, the Hall of the Council of State, and the Galleries of Casts from the Antique, thus throwing open to the public the entire building, has created considerable interest in Paris. The Gallery of Spanish Paintings and the Naval Museum attracted the largest share of public attention. Besides the copies of Raphael, placed in the Hall des Sept Cheminées, are rooms, each particularly devoted to the works of some distinguished painter; among which are exhibited the admirable Cartoon of Le Guido, the Chartreux of Vernet, the Atala and Endymion of Girodet, the Education of Achilles of Renaud, and the Marcus Sextus of Guerin. In the Egyptian Gallery no new arrangement has been made. The three new halls opened to the public are the saloon of Henry II., the bedroom of Henry IX., and the cabinet of Anne of Austria. In the Hall of Sculpture (la Renaissance) is exhibited the tomb of Isabella the Catholic, and of Ferdinand, and other valuable works of art hitherto unknown in France. In the new galleries, under the colonnade, is collected a most complete series of casts from the antique, consisting of the bas reliefs in the British Museum, from the Parthenon, the Horses of Venice, the Laocoon, &c.

MISCELLANEA.

BURNING OF THE ROYAL EXCHANGE, LONDON.

The destruction of this extensive edifice, scarcely paralleled in the commercial buildings of Europe, is an event of too much importance to the arts of this country not to be noticed in our pages. In the present Number we shall confine ourselves to an account of the fire, and in our next we will give a general description of the building, if possible accompanied by a plan, showing the site and dimensions.

Soon after 10 o'clock on the night of Wednesday, the 10th instant, the fire broke out in Lloyd's coffee-room, at the north-east corner of the edifice, opposite the Bank. It was first discovered by one of the Bank of England watchmen, who gave the alarm at the gates, and the Bank engines were immediately brought. A strong party of the City police and night watchmen, and the soldiers on duty in the Bank, repaired to the spot, and expresses were sent to the fire engine stations, at which period no signs of the fire could be seen from the street. Considerable difficulty was experienced in obtaining entrance to the building, but when this was accomplished, the flames burst through the windows with great fury, and drove the people back. An extraordinary scene ensued: the whole neighbourhood was alarmed, and the tradesmen who held the small shops around the exterior of the building instantly commenced the removal of their goods. It was at once predicted that the whole building would be destroyed, and this foreboding was realized too correctly. The several engines, with 63 of the fire brigade men, reached the spot within an hour after the fire broke out. Before any water could be thrown on the building, it was necessary to thaw the hose and works of the engines, by pouring hot water upon them, and this caused some delay. For some time afterwards, owing to the intense frost, there was great difficulty in working the engines; while the fire continued extending in a south west direction, consuming the whole of the long range of offices belonging to the Royal Exchange Assurance Company.

At 12 o'clock, these, and Lloyd's establishment, the coffee room, the captains'-room, and the offices of the underwriters, presented one body of flame, which shot up to a great height, illuminating the Bank, St. Bartholomew's, St. Michael's, and St. Mary's churches. Every object was as visible as at noon day.

At one o'clock, the north and west sides of the Exchange were consumed, and the fire was rapidly approaching the new clock tower. The efforts of the firemen appeared not to have had the least effect; the flames extended rapidly over the building, proceeding from floor to floor, and running along the corridors with the greatest rapidity. At two o'clock the flames reached the tower, and the excitement of the assembled multitudes in Cornhill, Mansion house street, and the Poultry, became extreme. A thousand voices murmured, "It has reached the tower, it's all over." The appearance of the vast conflagration at this period was awful; the whole of the Exchange was completely enveloped in flames, and the heat was so great that the firemen and auxiliaries could scarcely pursue their labours near the burning mass. The interior wood work of the tower was speedily reduced to ashes; the musical peal of eight bells, with a tenor of about eighteen cwt., fell one after the other, carrying away every thing in their progress towards the pavement, including the roof and stonework, and the arch over the centre entrance. The clock had a very singular effect while the tower was burning. The plates of the dials became red-hot, and the hands pointed to the hour, twenty five minutes past one, when the wood work took fire, melting the chime barrels and the machinery in a few minutes. It is utterly impossible to describe the scene which presented itself to the eyes of the spectators; although the sky was unclouded, and the moon shone, yet its brightness was totally obscured by the dense volumes of smoke and flames which issued from the ruins; whilst a shower of fire was seen hovering over the houses to the south of the Exchange. At half-past two o'clock, a general opinion seemed to prevail that the offices of the Royal Naval Hospital, at the side of the Ex-

change, would not be reached, and several engines were ordered to be drawn up opposite Sweeting's Alley. On this being done, the hose were conveyed to the tops of the houses on the east side of the alley, which is a very narrow one, by which means the firemen had a perfect command over that portion of the Exchange, and torrents of water were discharged into the interior of the building; but notwithstanding all their efforts, the flames rapidly extended, and the firemen were obliged to retreat, in consequence of the great heat.

At half-past three o'clock the north-west and south sides of the immense building were burnt down; and the flames had reached the east, threatening the entire destruction of the range of shops and dwelling-houses connected with the Exchange, and forming the west side of Sweeting's Alley. At four o'clock, the fire was still raging with unabated fury. The wind, which was blowing fresh all the night, had increased almost to a tempest, and the immense area was one body of flame. The remaining wing, the east, shared the fate of the others, and with it the houses and shops in Sweeting's Alley, forming part of the main building. The firemen again got on to the roofs of the houses on the opposite side of Sweeting's Alley with their hose and branch-pipes, connected with eight powerful engines, and directed a plentiful supply of water over the shops and houses below them, by which they were kept cool and prevented from igniting. The eastern wing of the Exchange, like the others, was soon reduced to a heap of ruins by the flames spreading from office to office. The roar of the winds, and the rush and crackling of the flames, the falling of huge timbers, and the noise of the engines, occasionally intermingled with the shouts of the firemen, were deafening.

The walls in the interior of the Exchange next fell with a tremendous crash carrying with them the numerous statues of the Kings and Queens who have reigned in England from the time of William the Conqueror. At five o'clock, the fire was still raging; but all apprehension of danger to the surrounding buildings was at an end.

The origin of the fire has not been satisfactorily explained. It is stated to have arisen in the stoppage of one of the flues connected with the kitchen of Lloyd's Coffee-house. This department was separated from the rest of the building by a thick but old boarding, which, indeed, formed the only partition between the several offices on the first floor. To this want of a party wall may be traced the speedy ignition of the premises on all sides, a circumstance which, with a north east wind, would have been impossible, had such a partition existed.

The Railway Steamer.—Were any of the ancients to rise from their tombs, and to behold a steam-ship full of passengers darting up the Thames, or a train of carriages with 1,000 people flying along a railroad at the rate of 30 miles an hour, they would be surprised at the fact of their revisit to the same planet they had left, since 1000 years in the grave may probably seem no longer than a short siesta after dinner. Without rudder or rein—without tug or tow-rope—without chart or compass—without impulse from man, or traction from beast—this maximum of power in the minimum of space—this magic automaton, the Railway Steamer, darts forward on iron pinions, like an arrow from a bow, along its destined course. Devised by science, but devoted to industry—harmless as the dove, if unopposed, but fatal as the thunderbolt, if obstructed in its career, this astonishing offspring of human invention, this giant in strength, though a dwarf in stature, drags along, and apparently without effort, whole cargoes of commerce, merchants and their merchandise, artisans and their arts, travellers and their traffic, tourists and their tours, in short, every thing that can be chained to the tail of this herculean velocipede. It nearly annihilates distance between the inhabitants of a state, and thereby converts, as it were, a whole country into a city—securing all the good effects of combination and concentration, without the bad consequences of a crowded population. By the railroad, Liverpool and Manchester, Birmingham and the metropolis, are made contiguous cities, while wide and fertile tracts of country intervene.—*Dr. J. Johnson.*

Extracts from Captain J. T. Smith's Notes to his excellent Translation of a Treatise on Mortars and Cements, by L. J. VICAT.

"LIMESTONE.—An abundant supply of hydraulic limestone is distributed through England by the lias beds, which the geological maps represent traversing the island from north to south, commencing at Whitby, on the Yorkshire coast, passing through that county, and the west of Lincolnshire, bordering Nottinghamshire, thence following for some distance the east bank of the Trent, afterwards crossing Warwickshire and Gloucestershire, and making its appearance in various parts of Somersetshire, finally terminating near the junction of the counties of Devon and Dorset, in the neighbourhood of Lyme. 'This formation consists of thick argillaceous deposits, constituting the base on which the whole oolitic series reposes. The upper portion of these deposits, including about two thirds of their total depth, consists of beds of a deep blue marl, containing only a few irregular and rubbly limestone beds. In the lower portion, the limestone beds increase in frequency, and assume the peculiar aspect which characterizes the lias, presenting a series of thin stony beds separated by narrow argillaceous partings; so that quarries of this rock at a distance assume a striped and riband-like appearance; in the lower beds of this limestone, the argillaceous partings often become very slight and almost disappear, as may be seen in the lias tract of South Wales: beds of blue marl with irregular calcareous masses, generally separate these strata from the red marl belonging to the subjacent new red sand-stone formation. The limestone beds, towards their centre, where most from external mixture, contain more than 90 per cent. of carbonate of lime; the residuum has never been distinctly analyzed, but appears to consist of alumine and [illegible] iron, and in some varieties traces of silex have been found: towards the edges of the beds, however, where they come in contact with the alternating strata of clay, the proportion of alumine is, as might be expected, more considerable. This limestone is particularly characterised by its dull earthy aspect, and large conchoidal fracture; in colour it varies in different beds from light ash blue, or smoke-grey, to white; the former varieties usually constituting the upper; the latter, the lower portions of the formation. The blue lias, which contains much iron, affords a strong lime, distinguished by its property of setting under water.'—'The irregular beds consist of fibrous limestone and cement stones (septaria) so called, because used in making Parker's cement.'—*Conybeare and Phillips's Geology of England and Wales.*

"Towards the southern extremity of the line formation above referred to, the bed widens in extent, so as to include a small part of Glamorganshire, whence the celebrated Aberthaw limestone is procured. But of late years the valuable properties of this lime have acquired it a reputation at other points of the line above traced, as for instance, at Barrow-on-Soar, in Leicestershire, and Watchet, in Somersetshire, both of which will be observed to be within the limit of the same formation. It appears, however, that the quality of the lime is not uniform throughout the whole extent of its range, being in some places slightly less energetic than others, a circumstance no doubt to be attributed to variations in the quality, or proportion, of the alloy contained by it.

"DECAY OF STUCCOES.—During my superintendence of public buildings in the northern division of the Madras presidency, I made many endeavours to investigate the cause of the very speedy decay, in certain situations, of stuccoes, which in others, apparently similarly exposed, possessed the greatest durability; and I was soon led to observe the very injurious effects of alternations of moisture and dryness upon mortars composed of rich lime and sand, by noticing the almost constant failure of those mortars which exhibited a *mottled* appearance on first drying. This phenomenon, which is interesting when viewed in connexion with the future durability of a cement, consists in a distinct exhibition of the courses of the masonry through the plaster, the joints being clearly defined, sometimes on a darker, and at others on a lighter ground, and indicating at one time an excess of humidity in the spaces opposite the bricks, and at others opposite the joints. These appearances were generally confined to within a few feet of the lower portion of the walls, which parts alone were subject to the early decay I allude to; and as they take place in a climate not subject to frost, and denote a cause of the degradation of mortars hitherto unexamined, it may be useful to notice briefly the leading facts which were observed.

"Common stucco, when plastered on a wall of brick and mortar, generally presented the appearance, on first drying, of damp joints and dry spaces (opposite the bricks); and this seemed to be owing to the spongy nature of the bricks, which, unless fully saturated with water in using them, caused the stucco to part more speedily with its moisture in those parts over them than elsewhere. After the same stucco has once thoroughly dried, if the situation be damp, these appearances may be reversed, more especially if the bricks be of an absorbent kind, or ill burnt. In this case it appears that being kept constantly damp by sucking up moisture from the earth, they become more charged with it than the stucco itself, which is of a less permeable nature; and exhaling it during hot weather, render the *spaces* damp in comparison with the joint, which have remained dry. And it is remarkable also, that, in such a case, the phenomena may be again reversed by soaking the whole surface with water; for if the stucco be not a very compact one, so as completely to exclude imbibition, the subsequent desiccation will proceed so much more rapidly opposite the bricks, which will then be comparatively *dry*, that the joints will continue long damp after the spaces have ceased to be so. Stucco, covering walls built of brick and *clay*, I have always seen exhibiting dry spaces and damp joints.

"Roman cement, Mr. Loriot's composition stucco, and such as *set* on first applying them, I have generally observed to present an opposite appearance to common mortars in which the lime has been well tempered. The best mortars, when exposed in situations which occasioned the above phenomena, were liable to early ruin, sometimes within a week of their completion, the decay being invariably confined to the region in which they were manifested, such as were beyond the reach of the moisture remaining perfectly sound for years. The failure was accompanied by the separation of large flakes, which were detached from the body of the cement, leaving the mass in a crumbling and disaggregated state behind it. These flakes varied in thickness with the age of the mortar, a fact which led me to the supposition, that they might consist of the superficial crust of the regenerated mortar, separated from the part behind it by some internal changes, occasioned by the alternations of moisture and dryness; but I found it impossible to prove this point directly, from the difficulty of detecting the separation of a patch of the falling plaster, in time to find the parts in contact with it still in a caustic state."

NOTICES TO CORRESPONDENTS.

We have received the plans and elevation of a Roman Catholic Church, now being built at Rosemont, in the county of Westmeath, Ireland, by D. J. Henry, Esq., Architect, and we have also received some other designs of churches, all of which we are obliged to postpone for some time; if it should meet with the approval of the profession, we will publish a distinct work on churches, for which purpose we shall be happy to receive communications, elevations, sections, plans, and specifications of churches erected, or in progress.

If Mr. Prosser will refer to the plans and sections accompanying the new standing orders of the House of Commons for last session, or to the plans accompanying Mr Simms' work on "Sectio-Planography," he will find that Mr. Macneill's method of laying down the section on the plans is very different from either the mode recommended by Mr. Tredgold or by Mr. Churchill; consequently, we have not published the communications and accompanying drawings which he has done us the favour to forward.

It is our intention to give some particulars of the principal Exchanges in Europe and America, for which purpose we shall be thankful for any communications or information on the subject. It would be very desirable to have accurate dimensions of the plans, and also drawings, if any of our Subscribers could favour us with them.

We have received a valuable communication from Mr. [illegible], of [illegible], which came too late for insertion in this Number, upon experiments and calculations made by him, during the late severe weather, upon [illegible] [illegible] and [illegible], by means of his newly invented egg-shaped [illegible], with [illegible] [illegible].

Books for Review should be sent early in the Month.—Communications, on or before the 20th—and Advertisements on or before the 25th instant.

MR. BRUNEL'S EXPERIMENTAL BRICK AND CEMENT ARCH,

ERECTED IN THE YARD AT THE THAMES TUNNEL, ROTHERHITHE.

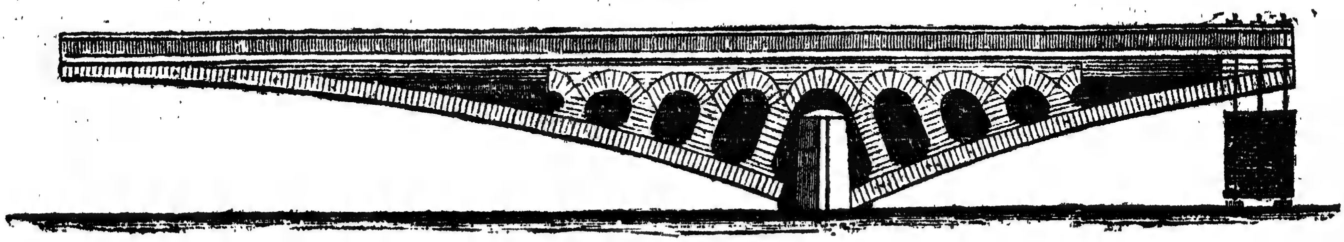


FIG. 1. ELEVATION.

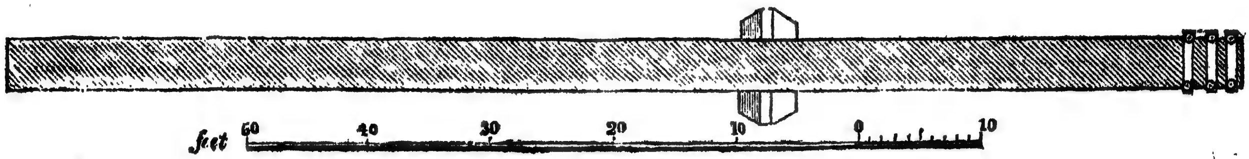

FIG. 2. PLAN.

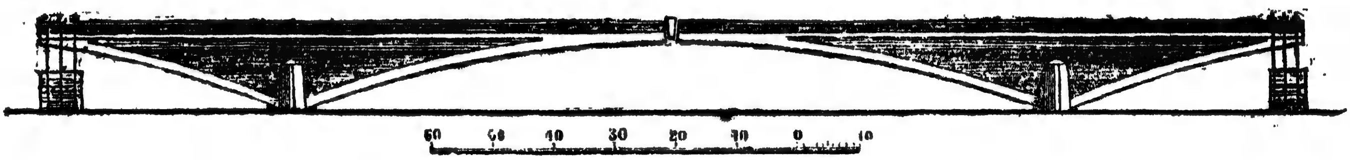

FIG. 3. ELEVATION OF A BRIDGE, CONSTRUCTED ON THE PRINCIPLES OF THE EXPERIMENTAL ARCH.

FIG. 5.

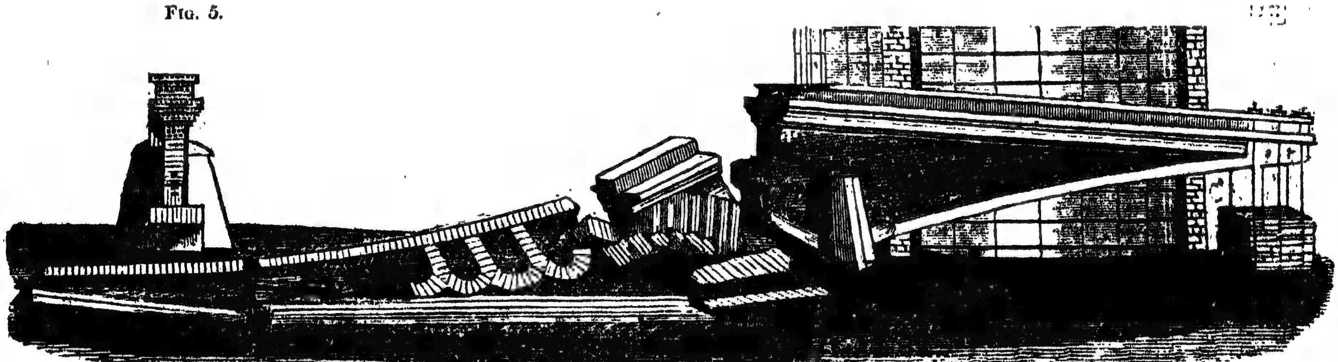

FIG. 4. THE ARCH AS IT APPEARED AFTER IT HAD FALLEN DOWN, ON THE 31ST OF JANUARY, 1838.

EXPLANATION OF DRAWINGS.

Fig. 1. Elevation of the experimental arch, as constructed by Mr. Brunel.

Fig. 2. Plan of same.

Fig. 3. Elevation of a bridge constructed on the principle of the experimental arch.

Fig. 4. Sketch of the experimental arch, as it appeared after it had fallen down on the 31st January last.

Fig. 5 is a section of the pier, showing the number of iron hoops, which are marked by dark lines or dots, and are laid in each course thus—in the upper course six pieces, the course under four pieces, the third, fourth, fifth, sixth, and seventh courses six pieces, eighth course five pieces, ninth course four pieces, tenth course three pieces, eleventh course two pieces; thence downwards are laid three pantile laths in the centre of every other course, lapped at meetings, in all ten layers or tiers; the lower tier is four feet six inches from the ground.

MR. BRUNEL'S EXPERIMENTAL BRICK AND CEMENT ARCH.

When we behold the stupendous works of man, we are often bewildered to account for the method of their construction, and this apparent difficulty is only to be removed by witnessing in any of these undertakings their slow and sure progress by the aid of machinery and art. There is, perhaps, no instance in which the force of this remark is more striking than in the art of bridge-building, of which this country possesses the finest specimens in the world, both for architectural beauty, magnitude, and solidity; the centerings upon which they were erected merit no small share of this remark. The above engraving (fig. 1) represents the *experimental brick arch*, invented by Mr. Brunel, Engineer-in-Chief of the Thames Tunnel, which at once introduces to the engineering world an entirely new feature, offering the united advantages of economy and utility. The superiority of this design is very evident; in the first place, centering is wholly dispensed with, and the curvature of the arch is obtained by means of a face-mould or sweep, of such convenient length as to be readily handled by the artificer. The principle upon which this bridge is chiefly founded, is (as may be seen by the drawing) by observing a strict equilibrium in the erection as it advances from each side of the piers; the ribs on both sides are executed for a distance of fifteen feet, without any other tension than the adhesive qualities of the cement and brick-work, of which this experiment is chiefly constructed. Above the height of five feet from the ground line, and to the extent of twenty feet either way, three fir pantile laths are inserted in the centre of every other course to the height of nine feet, and above that height hoop-iron, one inch wide, and one-sixteenth of an inch thick, are laid horizontally in each course of brickwork; the ribs of the two arches were gradually advanced by adding half a brick in thickness on to the projecting end, set in cement, which was done by the bricklayers standing on a scaffolding suspended from the top of the ribs, and advanced as the work proceeded; the two arches were then carried forward to the distance of twenty-five and thirty feet, the original extent which Mr. Brunel intended to confine his experiment: having so far succeeded, he was induced to extend his experiment still farther, and as there was a building immediately adjacent to the end of one of the ribs, he was obliged to confine his experiment to one of the ribs, which he was enabled to do by suspending a platform to the end of the shorter one, and as the longer rib advanced, placing weights on the platform to counterpoise the additional leverage of the longer rib; by these means he was enabled to extend the arch to the distance of forty-five feet. Mr. Brunel, finding that his experiment was crowned with complete success, was induced to carry it on still farther, which he ultimately did, by extending the arch to the surprising distance of sixty feet from the pier without any centering, support, or scaffolding on the ground; so particular was Mr. Brunel with the men, that he gave directions that if any of the bricklayers were found constructing any part of the arch from the ground, they were to be immediately discharged.

It will be perceived by the drawings (figs. 1 and 3) that the experiments of building one-half of an arch extending to sixty feet from the pier, was equal to a complete arch of 120 feet span, the rise or sine of the arch is ten feet six inches, and the radius of curvature is 175 feet, being the same as the centre portion of the ellipse of the large arch of London Bridge, and also the great arch of Chester Bridge; the weight suspended to the shorter rib to counterbalance the leverage of the longer rib was 62,700 lbs.; so nicely were the two ribs balanced, that by the most trifling addition or diminution of weight, they could with facility be raised or lowered. The following are the principal dimensions of the two ribs and the pier:—

The size of the pier on a level with the ground, is ten feet by four feet, which stands on pieces of three inch Yorkshire paving stone, let into the ground only eight inches below the surface; the height of the pier is eight feet, which diminishes gradually from the bottom to the top, and forms the abutment, or a centre, upon which the two ribs were counterpoised; the spandrell of the two ribs is one foot six inches thick, and, as will be seen by the drawing, is formed of a series of arches; the superstructure forming the cornice, and also the soffit of the arch, are three feet six inches wide, as shown on the plan, fig. 2, and section, fig. 5; the thickness of the arch is one brick and a half, or thirteen and a half inches; the span of the shorter rib is thirty feet, and the longer rib sixty feet.

The materials were composed of the best picked grey-stocks and Roman cement (manufactured by Messrs. Francis and White), mixed with an equal proportion of clean Thames sand.

The advantages of this system of bridge-building are, that one, two, or more arches, may be built over a river or a road, without any obstruction to the navigation or traffic, by advancing the brickwork from the pier or abutment equally, until they arrive at the centre allotted for the key-stone; it also saves the heavy expenses of centering, which is generally a very formidable item in the cost of bridge-building.

Mr. Brunel proposes to construct a bridge, by carrying across the river or road two ribs, similar to the experimental arch, which must be gradually advanced from the piers or abutment until they arrive at the central space left for the key-stone: if it should be found that the two ribs are not perfectly level, or in a straight line, they may be easily made so, as there is a degree of flexibility in the rib, which allows the arch to be raised or lowered, by adding to or taking off weights on the counterbalancing rib, as shown in fig. 1, and the two ribs may be as easily adjusted to a straight line; when they are thus properly adjusted, the key-stone is to be fixed, as shown in fig. 3; when that is done, the counterbalance weights may be removed. After one rib is carried across, the work is to be extended, by adding a nine-inch rim of brick-work set in cement, on each side of the rib, which will, on account of the adhesive qualities of the cement, unite very firmly to the first rib that was carried over. When one rim is thus completed, another rim is added, and so on until the intended width of the bridge is completed. If the counterbalancing rib, as shown in fig. 1, be carried forward simultaneously, and to the same extent as the adjacent rib, there will be no necessity for counterbalancing weights, which are only required when one rib is shorter than the adjoining one.

Since writing the preceding paper, we received a letter from Mr. Brunel, informing us that the arch had fallen down, and offered to give us his assistance and any information that we thought would be useful for the Journal; we accordingly hastened to the spot, and took a sketch of the arch as it appeared immediately after the fall, and previously to any part being removed. It suddenly broke down at a quarter past three o'clock, P.M., on the 31st of January, 1838. The sketch, fig. 4, represents the present remains and the nature of the different fractures. We will now proceed to explain the causes of the arch falling, which had stood for nearly two years, without any appearances of failure or fracture, supported on the pier only by its own equilibrium.

In the first place, it was never intended by Mr. Brunel, when he decided upon making the experiment, to carry it to the extent he did, consequently he provided a very slight foundation and pier. Secondly, a gasometer was erected immediately contiguous to the shorter rib, and the excavation for it abutted close to the pier. Thirdly, a trench was dug in front of the pier, during the late frost, for laying down some pipes to the gasometer, and when the thaw came on, the ground was supposed to have given or yielded. Fourthly, a north-easterly wind, blowing very strong against the unsheltered and longer rib (and the ground immediately adjoining the trench yielding by the thaw), the arch lost its equilibrium, and fell with a tremendous crash; and strange to say, so great was the tension of the iron, and adhesion of the cement, that notwithstanding the height of the fall, the entire fabric was not disturbed, but at the respective additions, as shown in the drawing, fig. 4.

So confident is Mr. Brunel of the principle of construction and the strength of cement, that he is of an opinion that even the aid of iron hooping is not necessary in the construction, and that hooping sticks may be in like manner substituted, by being first pitched, and then sprinkled with coarse sand, or brick rubbish, and well lapped over at their ends; or even New Zealand flax, laid together or knotted in long bands, pitched, sanded, strained tight, and laid in the work between the layers, might be used in lieu of the iron hooping, which Mr. Brunel is of opinion will answer every purpose until the key-stone is applied, which, of course, should in all cases, for the first rib, be as speedily as possible.

BALLARD'S ICE-BREAKING BOAT.

Much gratification was afforded to many of the inhabitants of Ledbury, last week, by witnessing the operation on the Herefordshire and Gloucestershire Canal of an ice-breaking boat, lately invented by Mr. Steven Ballard, engineer. Long pieces of timber, cased with iron, were fixed on the front of the boat; these timbers project before the boat, and form an inclined plane, sloping upwards from the under edge of the ice to near the middle of the boat. By these means, when the boat is drawn forwards, the ice is forced upwards instead of downwards, as is the usual way of breaking; and it is found the ice breaks remarkably easy when thus lifted from the water. The boat, with its apparatus, was drawn along the canal by two horses at a brisk pace, and the ice, which was in some places upwards of four inches thick, was ploughed up with great facility. The appearance of the boat when in motion, with the large pieces of ice continually rising over the front and falling on the sides, was very pleasing and interesting. Mr. Ballard has practised the method of breaking ice by forcing it upwards for some time past, but never with a boat and apparatus constructed purposely for this method before this winter. It is calculated that one horse will do as much work, with a machine of this kind, as four in the common way. Several boats loaded with coal were lying ice-bound at Over, near Gloucester, and in other parts of the canal, which were liberated, and followed the ice-boat into the basin of the Ledbury wharf, affording a useful supply of fuel to the inhabitants of the town and neighbourhood at the present inclement season.—*Birmingham Advertiser.*

REVIEWS.

The Churches of London, Nos. XIII. and XIV. By George Godwin, Jun., Architect, Associate of the Institute of British Architects; assisted by John Britton, Esq., F.S.A. London: 1838. C. Tilt.

This work still progresses with the same spirit and good taste as the former numbers, which we have previously noticed. No. XIII. contains the views and exteriors of St. Dunstan's in the West and St. Michael's, Cornhill; accompanying the description of St. Dunstan's is a spirited sketch of the old church, as it appeared in 1739. No. XIV. contains an external and internal view of St. Alban's, Wood Street, accompanied with some very proper remarks respecting Sir Christopher Wren, for having built "the church entirely different in style to the tower, which was standing; or why, having built the church, he did not afterwards, when called on to erect the tower, design that in conformity with it." There is also in this number a very neat engraving of St. Augustine's, Watling Street. Mr. Godwin has been particularly happy in selecting good points of sight for his perspective views, embracing the most interesting parts of the edifice.

A Practical Essay on the Construction and Management of Steam Engine Boilers.

A second number of this very clearly written book is before us, with a notice that Part III. will appear early in February, completing the work.

The following observations are well expressed, and we join our recommendation to that of the author, that railway directors would pay more attention than they have hitherto done to the suggestions of that class of mechanics who understand the method of carrying out the plans they propose, and not link themselves, so much as they are in the habit of doing, to the theories and crude observations of mere professors:—

It is a fact of the very utmost importance, and deserves the attention of those interested in railway speculations, that the very large item of expenditure in the reports of the Liverpool and Manchester Company, under the head of locomotive power account, varying from 30 to £40,000 per annum, is, in part, the result of want of sufficient boiler room. In saying this, it is not meant that larger boilers than those at present in use by that company are at all practicable on their line of railway; and much less is it my intention to cast the least reflection on any part of the direction, for there has been no lack of zeal in every one concerned in the management, to adopt every possible expedient that promised any chance of abatement under this head of disbursements; it is only mentioned to show the necessity of railway directors, generally, attending more to this point. Science has, as yet, done little or nothing for them; indeed the common fault of railway directors is too great a tendency to adopt the suggestions of mere scientific gentlemen, or the schemes of amateur engineers, because their ideas happen to be clothed in a scientific dress, in preference to plain, practical, and inexpressive improvements of a less ostentatious character.

We direct attention to the following statements of the author, connected as they are with the contrivances of a most ingenious mechanic, Mr. Hackworth, of Darlington.

Notwithstanding that the boilers of the locomotive engines on the Stockton and Darlington railway have been generally modifications of the old, or Trevethic plan, with a much greater capacity in proportion to the heating surface, than the multiflue boiler of Mr. Booth, and, therefore, generally considered to be on a less economical principle as to the application of heat, it is well known, that the cost to the company for drawing each ton per mile on the level, is not one half of what it is upon the Liverpool and Manchester line. The fact is certainly not in favour of high speed and high pressure; the speed of the Darlington locomotive being about twelve to fifteen miles an hour, which appears to be the velocity that gives the *maximum of useful* effect, while the pressure of the steam is only about forty pounds on the square inch. And it may here be observed, that I have had an opportunity of ascertaining, from a long series of very careful experiments, that even this pressure is still higher than that which is found to produce the best possible effect in a stationary engine, when working without either governor or throttle valve, as is the case with locomotives.

The superior economy of the Durham engines, is, no doubt, in part owing to the use of coal instead of coke, and not being compelled to burn their smoke (as they are obliged to do on most of the Lancashire railways), and this fact, it may be observed by the way, says nothing in favour of smoke-burning. It may also be stated, that but for the invention of the blast pipe, by Mr. Hackworth, of Darlington, which, in conjunction with Mr. Booth's boiler, at once doubled the efficiency of the locomotive engine, the prevention of smoke on railways would probably still present as great a difficulty as it yet does in factories.*

The author, in an extensive note to the above paragraph, seems to consider our observations upon the former part of his work, when speaking of the priming of boilers, in consequence of the accumulation of dirt, as scarcely borne out, in that we are not acquainted with "the preventive means—namely, the various mechanical methods of cleaning boilers without stopping them." Our observations were directed to the case of locomotive boilers, and we plead guilty to an ignorance of any practicable methods of cleaning such, or indeed any other boilers, without stopping; certainly the author has not pointed them out, for the various methods spoken of in page 63 and following, according to his own showing, fail in this effect, on account of the trouble attending the cleaning the boilers by hand in the usual way; but even if these were ever so successful for a factory boiler, they are wholly inapplicable to a locomotive; if, therefore, there be other means not expressed in his book, we shall be happy to receive them, and lay them before our readers, for we have never known a locomotive run for six days consecutively, with the very best water, but required to be cleaned out thoroughly, or the engine could not work.

The tendency of the water to rise into the cylinder, is always considerably promoted by the very usual situation of the steam pipe at the back end of the boiler; and this arises from the circulation of the water, which causes a uniform current at the surface, to set in the direction of the length of the boiler from the front end to the back. We may also here observe, that the presence of some kinds of dirt in the water, particularly if it be of a glutinous or mucilaginous nature, will cause the boiler to prime, whatever may be the amount of steam room. A small quantity of soap has a wonderful effect in this way; for all such cases, however, there are well known means of prevention, which will come more properly under our consideration in another chapter.

The following observations deserve attention:—

From what has appeared we may safely assume, that the space for *steam* in a boiler *ought not to be less* than half a cubic yard per horse power, and that the space for *water* certainly *ought not to be more*: therefore, generally, a cubic yard may be stated as the necessary capacity of boiler, for each horse power.

In enunciating the above proposition, I disclaim any right to being its first promulgator; and who first originated it, I have not been able to learn; I only know that it has been a current saying amongst the engineers in the neighbourhood of Newcastle-upon-Tyne, that a good steam-engine, ought to have an area of piston equal to twenty-seven circular inches per horse power, while the boiler ought to have twenty-seven cubic feet for the same. This is, probably, one of those maxims which occasionally become established in any trade where there is a good deal of practice, and it is, at least, as old as the first introduction of Boulton and Watt's patent engines to the collieries, in the counties of Durham and Northumberland. * * *

It is considered by bricklayers who have had the most practice, that in an engine chimney from twenty-four to thirty yards high, the common rule of making them twenty inches square inside at the top (400 square inches area) for each 20 horse boiler, is a good proportion. In Manchester, where, until lately, the engine chimneys were from twenty-four to thirty-six yards high, I always found the velocity of draught to be nearly proportional to the capacity of the chimney, reckoning by its narrowest dimensions. I have since observed, that the draught *is not improved* by raising the chimney much above forty or fifty yards, unless the width is also increased in a certain ratio. On the other hand I have also observed, that in chimneys under twenty yards high, if the width is greater than the above proportion, the draught is worse for it. At all factory chimneys, I would strongly recommend the use of the pressure or draught gauge, an instrument of as much use, in testing the effect of any alterations, as the water gauge, or even the steam gauge itself.

Rules are given, under the head of "resetting boilers," to which we direct attention; we do not quote them, as our extracts have been already too numerous.

We fully sympathise in the following remarks, and give our vote most heartily in favour of practical experience, *versus* the empty pretension of the mere bookworm theorist.

In choosing this method of investigation, and endeavouring to inculcate principles by applying them to practice, I am fully aware of the usual charge, as well as of the danger, of drawing conclusions from isolated facts and experiments; it may, however, be said, that although this empirical mode of instruction, by example rather than precept, may not be liable to very serious objections, yet that at any rate is is "unscientific;" however, it will do well enough, perhaps, if it is not "un English," for we are told that Brindley raised the first canal aqueduct in the world, in defiance of all the rules of science of the day; and in the same locality we have seen Stephenson successfully lay an iron railway across Chat Moss, quite contrary to the opinions of all the learned; and to compare small things with great, if we succeed in assisting the English manufacturer, or artisan, to obtain the greatest amount of power from a steam engine, at the least possible expense, we may safely continue to leave to the French and Ame-

* The original "*Sanspareil*" of Mr. Hackworth, which all but successfully competed for the prize at the opening of the Manchester and Liverpool Railway, may still be seen regularly working on the Bolton and Leigh Railway, apparently not much worse for seven years constant work, the boiler never having required any essential repair, while all its contemporary rivals that have escaped the fate of the "scrap heap," have been re-made, and mended over and over again, since the celebrated race at Rainhill—a fact which goes far to prove that the principle of this engine has not been so very much improved upon, except that it is not so well calculated for burning coke as coal. The Sanspareil may frequently be seen at the Kenyon Junction, waiting for the Bolton trains from Liverpool, and plans of it may be seen in Dr. Lardner's Work, Hebert's Mechanics' Encyclopædia, Wood on Railroads, the Mechanic's Magazine, and many other works.

nean writers, all scientific speculations on the subject of steam, as more suited to the closet of the philosopher than an English workshop or manufactory.

We had determined to spare further extracts, but the following is so much to our taste, and we think will be so useful, that we cannot resist adopting it into our pages.

The boiler we are about to examine has $17 \times 7 = 119$ square feet of water surface, and as it is supposed to have six square feet per horse power, it is equal to $119 \div 6 = 19{\cdot}83$, or nearly 20 horse power; if five square feet be allowed, then it is $119 \div 5 = 23{\cdot}8$, or nearly 24 horse power.

As estimating the power of a waggon boiler by the superficial extent of water surface is the customary mode in this district, and is in reality the best, when the boiler is at work and an exact measure of the heating surface cannot be obtained, we shall here give the proper formula for effecting that purpose by the slide rule:—

A	Gauge point, or square feet of water surface per horse power.	Width of Boiler in feet.
B	Length of the Boiler in feet.	Horse power.

An example for the above boiler is as follows:—

A	Gauge point = 6	Width 7 feet.
B	Length = 17 feet.	Answer 20 horse power.

If we take five square feet per horse for the gauge point, then it is—

A	Gauge point = 5	Width 7 feet.
B	Length = 17 feet.	Answer 24 horse power.

My object in giving these examples is to assist in facilitating the use of the slide rule among working mechanics, many of whom have complained to me, and justly, that the usual teachers of the use of this cheapest and best of calculating machines, begin by putting them into "dismals," which is far too sleepy a system for men who have worked hard all day.

Having digressed thus far, we shall merely add a formula for estimating the power of a steam engine from the diameter of the cylinder, without any given number of circular inches area per horse power:—

C	Gauge point, or circular inches area of piston per horse power.	Horse power.
D	Ditto	Diameter of Cylinder.

EXAMPLE:

C	Horse power... ... 18	Gauge point = 27
D	Diameter of Cylinder 22 inches	Ditto = 27

The intelligent mechanic will perceive that he can adopt any gauge point he likes best, or obtain one by measuring the diameter of the cylinder of any engine he approves of, by the same kind operation. Suppose, for instance, that a Boulton and Watt forty horse engine has a cylinder of thirty-two and a quarter inches in diameter, the gauge point is found as follows:—

C	Gauge point = 26	Power ... ... 40 horses.
D	Gauge point = 26	Diameter of Cylinder = $32\frac{1}{4}$ inches.

The rest of this number is occupied with rules and considerations for the best form and dimensions of fire-grate, with a chapter on *preventing circulation;* explaining Mr. Anthony Scott's patent apparatus for saving fuel, by placing hollow vessels, variously modified, within the boiler, displacing the water, and thus leaving a smaller amount of active, or boiling water, to be in contact with the heating surfaces; it is needless for us to explain this plan further, as, although saving fuel, it was found troublesome in practice, and has consequently fallen into disuse. We have gone through this book with much pleasure and instruction, and heartily recommend its attentive perusal to our readers.

The History and Antiquities of the Collegiate Church of Southwell, with Views of the Interior and Exterior, Plans, Sections, &c. By T. H. Clarke, Architect. Imp. 4to. Part I. Lond. 1838.

In our notice of another publication by the same author, we spoke briefly of the subject of the present work, which is certainly well selected, the building being a very interesting specimen of its class and the period to which it belongs, and deserving more attention than it has generally received hitherto. How it is described in Dickinson's History of Southwell we know not, but understand most wretchedly, in regard to the engravings, and are therefore not surprised to see it thus again brought forward. At present, indeed, we can judge but imperfectly of this new work, because the part before us contains no letter-press, and, with the exception of that representing the interior and exterior of one of the compartments of the choir, the plates here given consist only of views. These engravings are on stone, and, we presume, executed by the artist himself, for they exhibit more of spirit and effect, than of ability in the management of the tints. We are of opinion, that the style of lithography here chosen is not the very best for the purpose, since it partakes too much of the chalk manner, which, although favourable enough for subjects which admit of being treated in a free sketchy style, is not so well calculated for those which demand extreme precision of drawing, and to have all the forms clearly defined, even in the shadowed parts. That the utmost accuracy and delicacy of outline is attainable on stone as well as copper, we are convinced by many specimens of outline engraving so executed, which we have met with in German architectural plates; and, if we mistake not, those in Collie's "Glasgow Cathedral" are very ably drawn in the same manner. We are of opinion, therefore, it would have been better had Mr. Clarke treated his drawings, if not entirely as outlines, as principally such, with only indications of shadow in parts, just sufficient to produce relief.

At the same time, we are aware that many—we do not say architects—will no doubt prefer the mode he has adopted, as being the more picturesque. In this respect, the view of the north transept and chapter house is the best, owing to the sparkling distribution of light and shade. The general view of the east end of the church, on the contrary, and the north porch, are not so satisfactory. In the former, the perspective appears somewhat faulty, and in the other, greater depth of shadow is required within the porch itself, in order to bring it out and relieve it from the rest. Judging from the plate here given of the choir, we imagine that the geometrical drawings, which, after all, are those of primary importance, will be much better executed than the others, for this leaves very little, if anything, to be desired in regard to distinctness; and here, we may remark, the shadows are confined to the apertures of the windows externally, and the openings of arches within.

The style of this part of the interior is singularly elegant. The arches and their piers bear a great resemblance to those of the nave of Lincoln Cathedral; and the triforium range above them, consists of very lofty clerestory windows, which are seen through, instead of above them, a very unusual, if not unique arrangement. We look forward to the other sectional plates of the building with some degree of impatience, being assured this edifice must afford much that is particularly worthy of notice, and deserving of study, if properly made use of.

An Historical Sketch of the Royal Exchange, chiefly compiled from Stowe, and other Authorities. By Samuel Angell.

Mr. Angell has taken considerable pains to condense, in a small pamphlet, a faithful history of the building, together with an account of the various alterations which have occurred; illustrated with seven engravings, exhibiting the metamorphosing of the building from the foundation, in 1566, up to the last alteration made under the direction of Mr. George Smith.

A New Theory of the Steam Engine, and Calculation, by means of it, of every kind of Steam Engines, Stationary or Locomotive. By the Chev. G. De Pambour.

The above title describes the nature and objects of a Memoir read before the French Institute, at Paris, at various times, from February, 1837, up to the present period. An analysis of this paper is publishing in "Weale's Scientific Advertiser."

PART I.—Proofs of the inexactitude of the ordinary methods, and exposal of the proposed theory.

Section 1 is occupied exclusively in detailing the method usually adopted in this country to determine the power of an engine, by the multiplication of the pressure, area of the piston, length and number of strokes per minute, and representing this in horse powers.

Section 2 is devoted to the display of reasons why the usual mode of calculation is defective.

§ 2. *First objection against this method of calculation.*—This mode of calculation is liable to many objections, but we limit ourselves to the following:—

The coefficient adopted to represent the ratio of the practical effects to the theoretical, varies from $\frac{1}{2}$ to $\frac{2}{3}$, according to the various systems of steam-engines; that is to say, that from $\frac{2}{3}$ to $\frac{1}{2}$ of the power exerted by the machine is considered to be absorbed by friction and divers losses. Not that this friction and these losses have been measured and found such, but merely because the calculation that had been made, and which may be inexact in principle, wanted so much of coinciding with experience.

Now it is easy to obtain conviction, that the friction and losses which take place in a steam-engine can never amount to $\frac{2}{3}$, nor to $\frac{1}{2}$ of the total force it develops. It will suffice to cast an eye on the explanation attempted, with regard to this, by Tredgold, who follows this method in his treatise on steam-engines. He says (art. 367), that, for high-pressure engines, a deduction of four must be made from the *total* pressure of the steam, which amounts to a deduction of five on the ordinary *effective* pressure of such engines; and to justify this deduction, which however is still not enough to harmonize the theoretical and practical results in many circumstances, he is obliged to estimate the friction of the piston, with the losses or waste, at two-tenths of the power, and the force requisite for opening the valves and overcoming the

friction of the parts of the machine, at six-hundredths of that power. Reflecting that these numbers express fractions of the gross power of the engine, we must readily be convinced that they cannot be correct; for, in supposing the engine had a useful effect of 100 horses, which, from the reduction or coefficient employed, supposes a gross effect of 200 horses, 12 would be necessary to move the machinery, 40 to draw the piston, &c.! The exaggeration is evident.

Besides, in applying this evaluation of the friction to a locomotive engine, which is also a high-pressure steam-engine, and supposing it to have 2 cylinders of 12 inches diameter, and to work at 75 lbs. total pressure, which amounts to 60 lbs. effective pressure, per square inch, we find that from the preceding estimate, the force necessary to draw the piston would be 5,650 lbs., whereas our own experiments on the locomotive engine, the *Atlas*, which is of these dimensions, and works at that pressure, demonstrate that the force necessary to move, not only the two pistons, but all the rest of the machinery, including the waste, &c., is but 42 lbs. applied to the wheel, or 218 lbs. applied on the piston.

It is then impossible to admit, that in steam-engines the friction and losses can absorb the half, nor the third, much less the $\frac{2}{3}$ of the total power developed; and yet there do occur cases wherein, to reconcile the practical effects with the theoretical ones thus calculated, it would be necessary to reduce the latter to the fourth part, and even to less; and what is more, it often happens, that the same engine which in one case requires a reduction of $\frac{3}{4}$, will not in other cases need a reduction of more than about $\frac{1}{3}$. This is observed in calculating the effects of locomotive engines at very great velocities, and afterwards at very small ones.

The instances adduced by the author are exclusively those of locomotives, whose velocities are perpetually varying; and he quotes Tredgold, who shapes his rules for engines whose velocities are constant. The average velocity of a low-pressure engine should never exceed 220 feet in a second, excepting for engines of a very long stroke, when it may be a little increased, because, as these engines act by the gravitation of a column of steam, whose height is equal to that of the atmosphere, a variation from this velocity in any considerable degree either way would materially injure the effect: it has been found by Smeaton, that to produce the maximum effect, the velocity of the circumference of a water-wheel should not exceed three feet per second; so the same rule must apply to the action of a column of steam, which being an elastic body, and adapting itself more readily to the conditions of the machine, is allowed a velocity about one-fifth higher in consequence. Again, in calculating the powers of an engine, the result required is the limit of the greatest load it is capable of moving at the required velocity; this is another reason why the question of the supply of steam, which is more or less a constant quantity, need not enter into the calculation.

In a low-pressure engine, the steam being employed merely as a means of producing a vacuum, if it were possible to keep up steam in the boiler at one pound per square inch, instead of from five to seven (the usual pressure), without fluctuation, the action of the engine would be very much improved by the operation. We have seen a low-pressure engine attached to a high-pressure boiler, in which the steam ranged to thirty pounds per square inch; upon the steam pipe was fixed a self-acting apparatus, which reduced the steam to one pound per inch in the cylinder, and the improvement in its action over that produced from the former boiler, of from five to seven pounds pressure in the common way, was wonderful, both in fuel and the perfection of the vacuum.

§ 3. *Formulæ proposed by divers authors to determine the velocity of the piston under a given load, and proofs of their inexactitude.*—We have said that this problem was not resolved by the foregoing method. The following are the attempts made to that end by another way. Tredgold, in his treatise on steam-engines (art. 127 and following), undertakes to calculate the velocity of the piston from considerations deduced from the velocity of the flowing of a gas, supposed under a pressure equal to that of the boiler, into a gas supposed at the pressure of the resistance. He concludes from thence, that the velocity of the piston would be expressed by this formula,

$$V = 6{\cdot}5 \sqrt{h}\,,$$

in which h stands for the difference between the heights of two homogeneous columns of vapour, one representing the pressure in the boiler, the other that of the resistance. But it is easily seen, that this calculation supposes the boiler filled with an inexhaustible quantity of vapour, since the effluent gas is supposed to rush into the other with all the velocity it is susceptible of acquiring, in consequence of the difference of pressure. Now such an effect cannot be produced, unless the boiler be capable of supplying the expenditure, however enormous it might be. This amounts consequently to supposing that the production of steam in the boiler is unlimited. * * *

It occurs to us, that the author does not state Tredgold's formula with the exactness due to it. Tredgold, as we have before remarked, forms his rule for condensing engines, whose velocity must, under every condition of the load, remain uniform, or the effect will be injured. His theory of calculating the velocity of the piston, from considerations deduced from the flowing of a gas, &c., is most correct, and his formula correct also: the coefficient 6·5 is a deduction due to the friction through the pipe, derived from experiment; and he explains (article 138), "the quantity of steam generated, may be considered equal to the quantity consumed, in the same time, and that the boiler is of sufficient capacity to admit of its being taken at intervals without a sensible loss of elastic power; and as these conditions are essential to a good engine, we shall consider them to be fulfilled."

Thus, the observations indulged in by the author, to disprove the accuracy of Tredgold's formula, are not warranted by the circumstances of the case, because, if double, or treble, or any other quantity of steam were generated beyond that required to produce the effect, it would be blown off to waste.

In his treatise on railways (page 83), Tredgold proposes the following formula, without in any way founding it on reasoning, or on facts:—

$$V = 240 \sqrt{\frac{lP}{W}}\,,$$

in which V is the velocity of the piston in feet per minute, l the stroke of the piston, P the effective pressure of the steam in the boiler, and W the resistance of the load. But as this formula makes no mention either of the diameter of the cylinder, or of the quantity of steam supplied by the boiler in a minute, it clearly cannot give the velocity sought; for if it could, the velocity of an engine would be the same with a cylinder of 1 foot diameter as with a cylinder of 4 feet, which expends 16 times as much steam. The area of heating surface, or the vaporization of the boiler, would be equally indifferent: an engine would not move quicker with a boiler vaporizing a cubic foot of water per minute, than with one that should vaporize but $\frac{1}{4}$ or $\frac{1}{20}$. Hence this formula is without basis.

Wood, in his treatise on railways (page 351), proposes the following formula also, without discussion,

$$V = 4 \sqrt{\frac{l\,P}{W}}\,,$$

where V is the velocity of the piston in feet per minute, l the length of stroke of the piston, W the resistance of the load, and P the surplus of the pressure in the boiler, over and above what is necessary to balance the load W. This formula being liable to the same objections as the preceding, is also demonstrated inadmissible *à priori.*

The above observations we think just. It has been shown by Watt, and the fact has been noticed by almost every writer upon the steam-engine since, that the evaporation of a cubic foot of water per hour is the identical measure of a horse power; and it is singular that, in the discussion which the Cornish engine question has undergone, this simple mode of testing the performance of one species of boiler over another, should not have been resorted to. The boiler is *cæteris paribus* the depository of power, the engine is a mere adaptation of means to render this power available; therefore, we have been accustomed in our practice, in connexion with locomotives, to take the evaporating power of the boiler in cubic feet per hour, as the exact measure of the power of the engine. We readily concede to M. Pambour, that the usual mode of estimating the power of engines, as applied to locomotives, is wholly inadmissible, and this is only admitting what has been well known in this country, amongst practical men, ever since the introduction of the locomotive.

§ 4. *Succinct exposition of the proposed theory.*—After having made known the present state of science, with regard to the theory and estimation of the effective power of steam-engines, it remains to exhibit the theory we apply to them ourselves.

It is well known, that in every machine, when the effort of the motive power becomes superior to the resistance, a slow motion is created, which quickens by degrees till the machine has attained a certain velocity, beyond which it does not go, the motive power being incapable of producing greater velocity with the mass it has to move. Once this point attained, which requires but a very short space of time, the velocity continues the same, and the motion remains uniform as long as the effort lasts. It is from this point only the the effects of engines begin to be reckoned, because they are never employed but in that state of uniform motion; and it is with reason that the few minutes, during which the velocity regulates itself, and the transitory effects which take place before the uniform velocity is acquired, are neglected.

Now, in an engine arrived at uniform motion, the force applied by the motive power forms strictly an equilibrium with the resistance; for if that force were greater or less, the motion would be accelerated or retarded, which is contrary to the hypothesis. In a steam-engine the force applied by the motive agent is nothing more than the pressure of the steam *against the piston*, or *in the cylinder*. The pressure therefore in the cylinder is strictly equal to the resistance of the load against the piston.

Consequently the steam, in passing from the boiler to the cylinder, changes its pressure, and assumes that which is represented by the resistance of the piston. This fact alone exposes all the theory of the steam-engine, and in a manner lays its play open.

From what has been said, the force applied on the piston, or the pressure of the steam in the cylinder, is therefore strictly regulated by the resistance of the load against the piston. Consequently calling P′ the pressure of the

steam in the cylinder, and R the resistance of the load against the piston, we have as a first analogy,

$$P' = R.$$

To obtain a second relation between the data and the quæsita of the problem, we will observe that there is a necessary equality between the quantity of steam produced, and the quantity expended by the machine; the proposition is self-evident. Now, if we express by S the volume of water vaporized in the boiler per minute, and effectively transmitted to the cylinder, and by m the ratio of the volume of the steam generated under the pressure P of the boiler, to the volume of water which produced it, it is clear that

$$m\,S$$

will be the volume of steam formed per minute in the boiler. This steam passes into the cylinder and there assumes the pressure P'; but if the cylinders and steam pipes are properly protected against all the effects of external refrigeration, the steam preserves its temperature. Hence, in passing from the boiler to the cylinder, or from the pressure P to the pressure P', its volume increases in the inverse ratio of the pressures.

This is a very elegant exposal of the theory proposed, borne out by the reasoning contained in paragraph 5; but a great deal of the argument is used under the mistaken comparison of the action of low-pressure and high-pressure engines, as noted in our former remarks.

To apply our formula with reference to the same problem, viz.

$$a\,R = \frac{m\,S\,P}{a\,v},$$

we have nothing more to do than to substitute for the letters their value, taking care to refer all the measures to the same unit. In making then these substitutions, which give $P = 69 \times 144$ lbs., $m = 413$, $a = 1{\cdot}32$, and observing that the effective vaporization of the engine has been $S = {\cdot}80$ cubic feet of water per minute, we find,

1st case.—Effort applied by the engine at the given velocity, according to our theory, $\frac{413 \times {\cdot}80 \times (69 \times 144)}{298}$ . . . . . 11,002 lbs.

Effect produced, including friction and resistances, as above 10,561

Difference 441

2nd case.—Effort applied by the engine at the given velocity, according to our theory, $\frac{413 \times {\cdot}80 \times (69 \times 144)}{434}$ 7,562

Effect produced, including friction, &c. 7,707

Difference 145

Mean difference of the two cases . . . . 293 lbs.

It appears, then, that by this method, the useful effect is found with a difference only of 293 lbs., a very inconsiderable difference in experiments of this kind, wherein so much depends on the management of the fire.

The application of the new mode of calculation is here satisfactorily displayed; but we think, for all practical purposes, the power of an engine may be sufficiently and accurately determined by the quantity of water evaporated alone, as the engineer, if his boiler produce more steam than is needed, has only to regulate his fire accordingly, or the boiler might be made very easily to regulate itself, the same as in a stationary engine.

2°. To continue the same comparison of the two theories, let it be required to calculate what quantity of water per minute the boiler ought to vaporize, to produce either the first effect or the second. The method followed by the ordinary theory, again consists in previously supposing that the volumes described by the piston has been filled with steam at the same pressure as in the boiler, and then in applying to it a fractional coefficient to account for the losses.

Now, in the 1st case, the volume described by the piston at the given velocity, is $1{\cdot}32 \times 298 = 393$ cubic feet. Had this volume been filled with steam at the pressure of the boiler, it would have required a vaporization of $\frac{393}{413} = {\cdot}95$ cubic feet of water per minute.

But the real vaporization was but ·80; wherefore, in the first case, the coefficient necessary to lead from the vaporization indicated by the ordinary calculation, to the real vaporizaton, $\frac{{\cdot}80}{{\cdot}95} = {\cdot}84$.

In the second case, we find in the same manner, that the coefficient should be ·57, whence, in this problem, as in the preceding one, no constant coefficient whatever can suffice.

Performing, however, the calculation with the mean coefficient, ·70, we find,

1st case.—Vaporization per minute, calculated by the ordinary theory, with the coefficient, ·70, $\frac{1{\cdot}32 \times 298}{413} \times {\cdot}70$ . . . . ·67

Real vaporization . . . . ·80

Error . . . . ·13

2nd case.—Vaporization per minute, calculated by the ordinary theory, with the coefficient, ·70, $\frac{1{\cdot}32 \times 434}{413} \times {\cdot}70$ . . . . ·97

Real vaporization . . . . ·80

Error . . . . ·17

The mean error committed is then ⅕ of the vaporization, and being as it is a mean, it may, in extreme cases, become ⅓, or amount to half of the whole vaporization.

This is the error committed in seeking a coefficient *expressly* for the vaporization. But when the coefficient, determined in the preceding case, that is, by the comparison of the theoretical and practical effects, is used as a divisor, as by many authors it is, much greater errors are induced, which we will show by an example farther on.

In our theory, on the contrary, the vaporization necessary to set in motion the resistance a R at the velocity v, is given by the formula

$$S = \frac{a\,R \times v}{m\,P}.$$

We have then,

1st case.—Vaporization calculated from our theory, $\frac{10{,}561 \times 298}{413 \times (69 \times 144)}$ . . ·77

Real vaporization . . . . ·80

Difference . . . . ·03

2nd case.—Vaporization calculated from our theory, $\frac{7707 \times 434}{413 \times (69 \times 144)}$ . . ·82

Real vaporization . . . . ·80

Difference . . . . ·02

3°. Lastly, in the case of finding the velocity of the piston, supposing the resistance to be given, any method similar to the ordinary one must inevitably lead to errors; but we must dispense with comparison, since this problem has never been resolved, and we shall therefore in this case merely show the verification of our own theory. The formula relative to this problem is

$$v = \frac{m\,S\,P}{a\,R}.$$

We find then,

1st case.—Velocity of the piston in feet per minute, calculated from our theory, $\frac{413 \times {\cdot}80 \times (69 \times 144)}{10561}$ 311

Real velocity 298

Difference 13

2nd case.—Velocity of the piston from our theory, $\frac{413 \times {\cdot}80 \times (69 \times 144)}{7707}$ 426

Real velocity 434

Difference 8

It consequently appears, that in each of the three problems in question, our theory leads to the true result, whereas the ordinary theory, besides that it leaves the 3rd problem unresolved, may, in the other two, lead to very serious errors.

It must be observed, although we coincide in the accuracy of the above, that a boiler must be formed to meet the extreme requirement of the engine, all the cases between this, and the least effect, must of course be matters of adjustment, and this extreme case will be the steepest gradient, the heaviest load the engine is required to drag over it, and the highest velocity up the ascent.

§ 7. *Of the area of the steam passages.*—There is yet one point which it is necessary to examine, and that is the area of the opening of the regulator.

The ordinary theory recognises in this opening an effect of great importance to the engine, since it affirms, that, by increasing or diminishing it, any desired pressure may be produced in the cylinder. Yet no means are given to ascertain that opening, and the calculation is always performed with the same coefficient, whatever that opening may be.

Before abandoning this comparison, we request attention to an effect, in calculating by the ordinary theory, which we have already mentioned, but which is here demonstrated, viz., that this calculation gives the same force applied by the engine in both the cases considered, notwithstanding their difference of velocity; and such will always be the result, since the calculation consists merely in multiplying the area of the piston by the pressure in the boiler, and reducing the product in a constant proportion. This theory therefore maintains, in principle, that the engine can always draw the same load at all imaginable velocities. Again we see, that, in the same calculation of the load or effort applied, the vaporization of the engine does not appear, which would imply that the engine would always draw the same load at all velocities, whatever might be the vaporization of the boiler, which is inadmissible.

We shall also remark, that in calculating by the ordinary theory the vaporization of the engine, no notice is taken of the resistance which the engine is supposed to move; so that the vaporization necessary to draw a given load would be independent of that load—another result equally impossible.

To these omissions, therefore, or rather to these errors in principle, are to be attributed the variations observable in the results given of the ordinary theory in the examples proposed. * * *

In the theory we propose, on the contrary, the opening of the regulator, or at least the effect it produces, are taken into account, though its direct measure does not ostensibly appear in the formulæ. To render this fact perfectly clear, we shall first establish what are the real effects of the regulator.

We shall first prove that the degree of opening of the regulator can have no influence on the pressure in the cylinder, but that it acts, on the contrary, only

on the pressure in the boiler; we shall afterwards show, that whatever be the degree of that opening, the formula will always account for it, and continue to give the true effect produced; finally, we shall examine what are, in each circumstance, the changes induced in the effect, by reason of the greater or less opening of the regulator. * * * *

As the total quantity of water vaporized in a given time may be directly measured by the supply, the question reduces itself to estimating that which is lost by the safety-valve, in order to subtract it from the former. This evaluation is readily made; first, by taking note of the height to which the valve is raised at the moment of the loss, which the length of the levers of the safety-valves, and the graduated scale with which they are furnished, render extremely easy; and, second, letting the regulator be completely closed, so as to force the whole of the steam produced to escape by the valve, and noting again the height to which the valve is raised. The proportion of the first elevation to the second will be the ratio of the vapour lost to the total vapour produced. This is the means we have used with locomotive engines. Should the evaluation not appear sufficiently precise, the waste vapour may be condensed in a separate vessel, and the quantity of water measured. It will always then be easy to know the *effective* vaporization of the engine; and consequently, by introducing it into the formulæ, we shall continue to have the true effect produced.

Here, again, is an unfair comparison of the two systems; the ordinary system invariably supposes a determinate and uniform velocity of the piston, in which case it is most true that, by increasing or diminishing the opening of the regulator, any desired pressure may be produced in the cylinder, because thus the density of the steam in the cylinder, and that in the boiler, may be made to coincide in any ratio; but the author, supposing that the piston is a safety-valve, and to be allowed any velocity the steam may impress upon it, supposes a case which never occurs in practice, not even in locomotives; if it were so, then of course the narrowing or opening the regulator could only affect the boiler, as the piston moving faster or slower, according to the quantity of steam admitted into the cylinder, the pressure in the cylinder will remain the same.

We have made large extracts from the above very interesting paper, and hope, for the satisfaction of English readers, that the entire memoir will soon appear in a distinct shape.

An Engraving of the Dutton Viaduct, on the Grand Junction Railway, over the Valley of the Weaver, from a Design by G. Stephenson, Esq., and erected under the direction of J. Locke, Esq. Wrightson and Webb, Birmingham.

This is a spirited and beautifully executed engraving, on steel, from a picture by Thomas Creswick, Esq., exhibiting that stupendous work of art. The Dutton Viaduct consists of twenty arches of solid stone, the span of each being sixty feet; the height from the water to the top of the parapet wall seventy-three, and the entire length over the valley 1,400 feet. The foreground of the landscape is very beautifully drawn, interspersed with figures, which give a lively and delightful effect to the scenery.

An Historical and Topographical Account of Cassiobury, the Seat of the Earl of Essex. By John Britton, F.S.A., H.M.R.I., B.A., &c. Folio. London: 1837.

Whether this is to be regarded as a posthumous work given to the world now that Mr. Britton is professionally defunct, or a resuscitation of his former publishing career, it cannot be termed one at all creditable to him, either on account of selecting such a subject for illustration, or for the mode in which he has thought proper to describe it, including in this latter sense the plates as well as the letter-press. The house itself exhibits about as tasteless and inconsistent an application of Gothic, as has been perpetrated in modern times on a similar scale; is, besides, a wretched jumble of that and other styles; and withal very badly planned within, as well in regard to display as to convenience as a residence. However, having made choice of it for better or worse, we conceive that Mr. Britton was bound to show it fairly and intelligibly; instead of which he takes care not to enlighten us too much, for all that he permits us to behold of it is two or three general, and we must say, huddled up views of it, the interior of the library and great cloister, and a ground-plan of one floor. There is not a geometrical elevation of any part, not a single section, not a single piece of detail; it is unnecessary therefore to add, that the work would be very imperfect and unsatisfactory, even were the views themselves well executed. Very far, however, from being so, they are exceedingly incorrect and tasteless, we might say slovenly, both in regard to drawing and to engraving. We say incorrect, because, however bad the forms and details may be, we cannot imagine them to be so vile as here represented. Since the library has been selected for an interior view, we must suppose that it is at least as handsome as any of the apartments; yet it is certainly a very common place, not to say vulgar room, fitted up in a style equally remote from refined elegance, or imposing dignity. Nevertheless, in the letter-press, every thing, as far as it is described or noticed at all, is painted *en beau*. On this occasion, Mr. B. is perhaps some less lavish of sugary terms than is his wont; in fact, as brief as in common decency he could be, in what he says of the house itself, carefully eschewing aught that might be taken for criticism on it. *En revanche*, he has dished up a strange rigmarolish chapter about Cassibelaunus, which, if it has very little to do with my Lord Essex's residence, might, *mutatis mutandis*, be made to serve for that of any other nobleman quite as well. We saw how matters stood when we read in the first sentence about Athens and Thebes. Really it is full time that a stop should be put to all that sort of inane, schoolboy pomposity, and commonplace hoisted upon stilts. It may sometimes be amusing, but then it is always at the writer's own expense; and in this instance we think that Mr. Britton has overdosed his readers with it. By very far the best thing in the books are the wood-cuts of the different cottages and lodges in the grounds, which, as vignettes, are sparkling and spirited enough. Yet these we apprehend will hardly reconcile the purchasers to paying three guineas for such a volume.

Public Works of Great Britain. Edited by F. W. Simms, C.E. London: John Weale, 1838.

In our last number we gave a hasty review of the important volume before us; we have since carefully perused the work, which, we are happy to say, fully confirms our previous remarks. It is, doubtless, one of national importance, and, if we mistake not, will become a standard book of reference for the profession. It contains upwards of 150 engravings, beautifully and accurately drawn, and reduced from the originals; each plate is in itself a study. We sincerely hope that both the editor and publisher will be amply repaid, for their labours, and the heavy expenses that must have been incurred in bringing out such a *stupendous* volume. We very earnestly recommend it to the notice not only of the profession, but to the public in general, who will derive, by an inspection and study of this work, some idea of the magnificent and noble works that are now progressing in Great Britain.

The volume is subdivided into four divisions, viz.:—

Division 1.—Railways.

Division 2.—Canals, Bridges, River-walls, and the Docks and Port of Liverpool.

Division 3.—Turnpike-roads, Iron, Steel, and Gas-works.

Division 4.—Survey of the Port of London.

It is our present intention to confine our remarks to the first division, which comprises the drawings of the principal works on the Birmingham, the Great Western, the Southampton, the Greenwich, the Croydon, the Birmingham, Bristol and Thames Junction, and the Glasgow and Gainkirk Railways. The first and principal portion of this division is that of the *London and Birmingham Railway*, which is now in a forward state of completion, and will be, when finished, a lasting monument of the skill, ingenuity, and taste displayed by the Engineer-in-Chief, Robert Stephenson, Esq.

The first plate, commencing the work, is that of the entrance to the Primrose-hill Tunnel: it is admirably engraved, the design is particularly well adapted for the situation, and displays considerable taste and judgment; the architectural character is original, and participates in that of the massive Italian rusticated style. The next plate we cannot write in the same terms of praise, as it but ill represents the two noble and well-proportioned chimneys belonging to the steam-engines at the Camden Town station, which stand, like the obelisks of the ancients, indicating the entrance to some great work, as in the present case. Here, may be considered the commencement of the railway, and the depôt for the transportation of all the goods, which will be forwarded from the manufacturing towns, or the great workshops of England, to the metropolis. The next plates show the depôt, and the admirable arrangements made at the London terminus, Euston-square and Camden Town.

In all great travelling establishments the utmost perfection in the multifarious arrangements becomes essential to prevent confusion, and to facilitate business. If order and precision had been found necessary in the smaller establishments to which we have hitherto been accustomed, how much more essential must it be to facilitate the traffic of so immense a concern as that of the London and Birmingham Railway, where, comparatively, such numbers of persons are going and returning at each departure and arrival of the trains, and where, without a most perfect system of management throughout its numerous details, business would be retarded, the passengers' goods mislaid or lost, and inextricable confusion would result. The fact, however, is far otherwise; the whole business is conducted with a precision resembling the movements of our most admirable machinery; the arrangements of the offices of the depôt or passenger station are well contrived, and upon a most magnificent scale. Plate 4 contains a ground-plan of the London station of this railway, at Euston Square; the grand entrance, as before observed, is now (October, 1837) in the course of erection; the principal or public carriage entrance leads to an area enclosed by a wall marked A A A, &c., thus separated from the various lines of railway, it must greatly tend to prevent con-

fusion. Beneath the colonnade are doors leading through the various offices to the departure stage, which is an admirably paved platform, from which the passengers pass into the various carriages; the arrows point the direction in which the departing and returning trains move. On the opposite side of the station an arrival stage or platform is erected, similar to the one above-named, and thus, by separating the arrivals and departures, another source of confusion is avoided.

The locomotive engines do not come to the station at Euston Square, but stop at that near the Hampstead Road, immediately on the north side of the Regent's Canal, nearly one mile distant. An inclined plane,* commences at Wriothesley Street Bridge, and terminates at the Regent's Canal; in returning, the trains *pass down* this inclination by the action of gravity, and their ascent on departure is effected by attaching them to an endless rope, which passes round a sheave sunk below the level of the ground near Wriothesley Street Bridge, and passes over a vertical sheave (Plate 5.) at the other extremity of the inclined plane, on the north side of the iron bridge over the canal; this sheave is also beneath the surface of the railway; the rope then passes round a horizontal sheave (called in the plan a tightening sheave) to another vertical one, or previously round a smaller intermediate vertical sheave, when a greater degree of friction is required; this brings the rope again above the surface, and in the direction of the first sheave at Wriothesley Street Bridge, thus constituting an endless rope. In order to give motion to the rope, two marine steam-engines, of sixty horse power each, are applied to turn the largest vertical sheaves on each line of railway; for it may be observed from the plan that two double lines of railway connect the Euston and Camden or Hampstead Road stations. In order to keep the endless rope always in a proper state of tension, there is an admirable contrivance which acts, in this case, as a spring; thus, the horizontal or tightening sheave (Plate 5) is fixed on a stage which is moveable, on a pair of rails (or railway) in the direction of the rope; from this stage a rope or chain passes over a roller into a well a little distance in its rear, and there suspends a counter-balancing weight; this weight is sufficient to draw the tightening sheave with considerable force towards the well, and thus keeps the rope in the requisite degree of tension, however the weights of the different attached trains may vary. The whole of these extensive works, of which the plan is represented at Plate 5, are beneath the surface of the railway, or underground, and therefore are invisible from above, with the exception of the two admirably proportioned chimneys which rise from the surface of the ground on each side of the railway to a towering height, and which have so imposing an effect. They are represented in perspective in Plate 3, as seen from the south or London side of the iron bridge which crosses the Regent's Canal; the details of their construction in plan, elevation, and section, are also given in Plate 5, accurately reduced from the original working drawings.

The Euston Square station is that intended for passengers, and the Camden station for heavy goods and merchandise, for which it is particularly adapted, being at the side of the Regent's Canal, by which means a water communication may be obtained for the merchandise and produce of the manufacturers of the midland counties, with the shipping in the port of London, and hence with the whole world.

The Roof of the Passengers' Arrival and Departure Shed, at Euston Grove (as represented in Plate 7), has a very light and elegant appearance; it is constructed principally of wrought-iron, the brestsummers, columns, and gutters only being of cast-iron. The entire width is eighty feet, formed in two spans of forty feet each, a row of iron columns and brestsummers supporting the rafters in the centre and outside, as shown by the engraving, and on the opposite side by iron corbels built in the wall, and further secured thereto by strong bolts and nuts; the rafters are six feet eight inches apart, and are of wrought iron, in form of the letter T; the slate battons, as they may be called, are of angle iron, firmly rivetted to the back of the rafters at such a distance as the slates require, and to which they are secured by strips of copper. The roof is firmly tied from side to side by a tension rod of one inch and a quarter diameter to each pair of rafters, and is further supported and braced by strutts of T iron and suspension rods, with nuts and screws to adjust their length, as shown in engraving. The entire length of the roof is two hundred feet; the gutters are cast in lengths of ten feet each, joined together by flanges and bolts, and so fixed as to form an incline towards each column, which being cast hollow and having a pipe connected with a drain, they form a convenient and easy conveyance for rain from the roof. (Plate 7.)

The Roof of the Locomotive Engine House, at Camden Town, is of very similar construction to the one above described; the rafters are of T iron, and the slates are supported by angle iron rivetted to the rafters. There are cast-iron chairs secured down to a stone coping on the walls, and from which the rafters spring; each pair of rafters is tied by means of a tension rod, and otherwise supported and braced by strutts of T iron, and suspension rods of round iron, which make the whole very firm, and gives it a light and pleasing appearance.

The only part we do not like in the roofs, is placing the tie-bolts diagonally, instead of horizontally, and if the flange of the struts had been in the centre instead of the top, they would have been much stronger. The plates which follow, exhibit the details of several bridges on the extension line between Camden Town and Euston-square; they are beautifully drawn in detail. The Stanhope-place bridge of two arches appears to be rather of a hazardous construction, particularly if the thoroughfare over the bridge be considerable; the details of the Park-street bridge, constructed of iron ribs, is instructive and deserving of study; so is the bridge over the Regent's Canal, the architectural effect of the stone piers is in good keeping with the structure. The next plates exhibit the viaduct of five arches over the river Colne, near Watford, and the bridge of three arches over the excavation south of Watford tunnel; the drawing of the skew, or oblique bridge, at Box-moor, clearly shows the construction of the brick and stone-work; the angle of the skew is thirty-two degrees, the span of the arch on the face is thirty-nine feet six inches, and across, at right angles, with the springing walls, twenty-one feet; rise of the arch five feet eight inches. The plate containing the section of the Primrose-hill tunnel and the Northchurch tunnel, exhibits the relative proportions of strength for the different strata through which they pass: the former tunnel passes through London clay, it is twenty-four feet wide and twenty-five feet high in the clear, the arch is three bricks thick, with an invert two bricks thick; the other tunnel passes through chalk, it is twenty-four feet wide in the clear, and twenty-three feet three inches high above the rails; the arch is two bricks thick, without an invert; it will thus be perceived, that the tunnel through chalk is one brick thinner than the other, besides the omission of the invert. The ten plates representing the working sections of the Blisworth excavations and embankments, for a distance of five miles, is of great utility to the student, and of considerable importance, as it shows him the necessary preliminary surveys and sections explaining the surface of the ground, and the nature of the strata of the ground-work through which the excavations are intended to be cut, which are necessary for the guidance and assistance of the contractors in making their estimates. The four following plates of the undersetting of the rock in the Blisworth cutting are admirably drawn and beautifully engraved in mezzotinto; they are copies of the original drawings. The design for the entrance of the Kilsby tunnel is in the Moorish style, and which, together with the details of the tunnel, are exhibited in ten plates.

The next plates show the different rails and chairs that have been adopted on the line: the first is the fish-bellied rail, weighing 50 lbs. per yard, with a complicated chair, which, we believe, is now abandoned; the next, is the rail generally adopted on the line for four feet bearings, weighing 65 lbs. per yard, of malleable iron *a*, which is secured by a key or wedge of compressed wood *c*, to a chair of cast-iron *b*, fixed to the stone sleepers *f*, by two iron pins or spikes *d*, driven into oak-plugs *e*, let into the stone; the sleepers are of granite, or Bramley-fall stone, two feet square and one foot thick. The annexed figures, one and two, show the con-

Fig. 1.

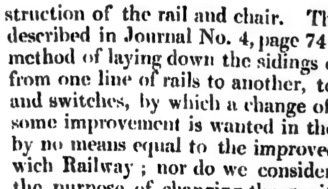

Fig. 2.

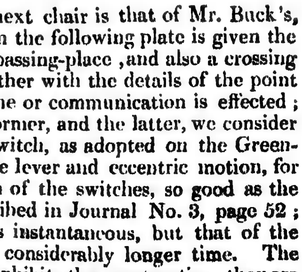

struction of the rail and chair. The next chair is that of Mr. Buck's, described in Journal No. 4, page 74; in the following plate is given the method of laying down the sidings or passing-place, and also a crossing from one line of rails to another, together with the details of the point and switches, by which a change of line or communication is effected; some improvement is wanted in the former, and the latter, we consider by no means equal to the improved switch, as adopted on the Greenwich Railway; nor do we consider the lever and eccentric motion, for the purpose of changing the position of the switches, so good as the lever with a balance-weight, as described in Journal No. 3, page 52; the change of motion by the latter is instantaneous, but that of the lever and eccentric motion occupies a considerably longer time. The drawing of the twelve feet turn-rails exhibits the construction, they are of cast-iron. The next plate contains a drawing of a first-class carriage; each carriage consists of three bodies or compartments, the extreme length, outside measure, being fifteen feet six inches; the length of each body, four feet eleven inches; the breadth, six feet; and the height, from floor to roof, four feet six and a half inches, all inside measure, and exclusive of the stuffing. The body is placed above the wheels, four feet from the ground, which we do not consider so good or so safe as the carriage with the body hung within a few inches of the ground.

* *Inclination of Extension.*

Great Western Railway. I. K. BRUNEL, Esq., Engineer. Plates 54 to 58.

The first three plates represent the plan, elevation, and section of the Wharncliffe Viaduct, over the river Brent, near Hanwell, one of the principal works on the line.

The execution of the Wharncliffe viaduct formed the contract No. 1, London division; the first contract let along the line, and about the first completed. This contract was obtained by Messrs. Grissel and Peto.

The arches are elliptical. The piers consist each of two massive square pillars, rising from a single plinth, and surmounted by simple capitals of stone of a somewhat Egyptian character. The wing walls are straight, and the space between them, which is hollow, is covered by a transverse arch, springing from wall to wall, the walls being inclined in the direction of the thrust resulting from the arch. The particulars of the work are as follows:—

		Feet.	Inches.
Total length, including wing walls		900	0
Eight main arches	Span of each	70	0
	Rise	17	6
Breadth between the parapets		30	0

The foundations of the piers were carried through the loose gravel about three feet into the strong blue clay, and the foot of each pier stands on an area of two hundred and fifty two square feet.

Upon striking the centering the arches followed from 1 inch and ¾ to 2 inches and ¼, the latter being the greatest fall, and the average being below 2 inches. The spaces between the arches were crossed by spandrell walls, and a floor of York landings laid upon the whole; the parapet and coping were added at a later period. The work was commenced in February, 1836, and was completed at the latter part of the summer of the following year.

The Brent is carried through a brick channel, beneath the second arch.

The viaduct is met at each end by an embankment; that on the east is formed from the excavation for the Railway towards Acton, consisting principally of gravel, and that on the west is formed entirely of a very hard binding gravel, obtained from side cuttings at the top of the hill.

We have our fears for the safety of the two arches at each end of the viaduct, unless strong cross-ties of iron have been introduced, which are not shown in the drawing, as we consider that the heavy locomotive rolling over the arch will have a powerful effect, and the thrust become so great, that it will have a tendency to force out the springing walls, notwithstanding their great inclination or batter.

The next two plates represent the Maidenhead Bridge.

Maidenhead Bridge.—This bold and magnificent undertaking is represented in plates 57 and 58. It consists of two arches, each of one hundred and twenty-eight feet span, with an intermediate pier of thirty feet in width. The materials of which this structure is composed is almost entirely of brick, with a very small portion of stone. These arches will be the first of such a magnitude turned wholly in brick. The result, which will now very soon appear, will, doubtless, confirm the high reputation for science and enterprise enjoyed by the eminent Engineer who designed, and is now executing, the work.

London and Southampton Railway. Plates 59 to 64.

Exhibit several common-place bridges, possessing neither novelty nor skill in the construction.

London and Greenwich Railway. Colonel LANDMANN, Engineer. Plates 65 to 70.

The four first plates represent the oblique arches over the Neikinger and Spa Roads. They are decidedly the best designed works on the line, and are a relief to the monotonous line of bricklayers' arches. These two bridges are constructed with one principal arch and two footway arches. The road is divided from the footpath by four Grecian-fluted Doric columns of cast-iron, and two piers of stone, which together have an air of lightness combined with the appearance of strength. The other two plates show the construction of the viaduct and the railway.

London and Croydon Railway. JOSEPH GIBBS, Esq., Engineer. Plates 71 and 72.

The first plate represents the bridge at New Cross. The Dover road is carried over the railway by a flat segmental arch, 30 feet span, the rise or versed line is only two feet. The width of the road is 64 feet, and is supported by 19 cast-iron curved girders or ribs; the parapet walls are supported by arches of brick set in cement. We very much approve of the plan of introducing iron plates between the lower parts of the ribs, which form a soffit in panels, and relieve the vacant and heavy appearance that otherwise would have been, had the space between been left open. The clear height under the bridge, above the surface of the rails, is 14 feet. The construction of this bridge forms a good precedent for railways which are obliged to pass under turnpike-roads, and where the height is confined, as is generally the case. The next plate represents the construction of the railway, which we shall notice hereafter, in consequence of the legal proceedings in Chancery, instituted against the Company by Mr. Parkin, for a *supposed* infringement of his patent.

Birmingham, Bristol, and Thames Junction Railway. W. HOSKING, Esq., Engineer. Plates 73 and 74.

The two plates show a happy combination of circumstances for exhibiting the skill and ingenuity of the engineer. At Wormwood Scrubbs, the railway will intersect the Paddington Canal, and a road; the railway will pass under the canal by means of a gallery 110 feet long, with lofty approaches, the clear headway being 14 feet 3 inches above the rails, with a clear breadth of 24 feet; a corridor or footway is formed on the side of the gallery to connect the two stations of the Company. The arch over the gallery is elliptical; the haunches are formed in brickwork, with a string-course or springer of stone for the abutments of cast-iron ribs which are to carry the crown of the arch, and filled in between with brickwork of *Rhodes's patent compressed bricks*, set in pouzzolana mortar: over the gallery is the aqueduct, formed in brickwork for the canal, which is to be diverted; over the canal and the tunnel is an iron bridge, suspended to two pair of segmental cast-iron ribs; in the centre is a carriageway 20 feet wide; and on the sides, between each pair of ribs, are the footways 5 feet wide; the span of the bridge is 70 feet. The appearance is extremely light, and we fear is really so, particularly if there should be hereafter much traffic over the bridge: the whole of the design exhibits considerable skill and judgment; the erection of the work is undertaken by Messrs. W. and L. Cubitt, for the sum of £7,680.

Glasgow and Gairnkirk Railway.—Plate 75 represents the cutting through the moss or peat which abounds on this line of railway.

Plate 76 is a comparison of rails drawn to one scale, excepting one, the Great Western rail, which appears to have been drawn by mistake at full size, as all the other rails are drawn at half the full size.

Locomotive Engines. Plates 76 to 78.

These plates are very beautifully engraved. One represents '*The Comet*' locomotive engine; the other "*Stephenson's patent locomotive engine, with six wheels,*" and her tender. We extract the following particulars from the work:—

It was many years after the first attempt to apply steam to the purposes of locomotion before it was satisfactorily ascertained that the adhesion of the wheels of an engine upon the rails was sufficient to effect its progression; and many contrivances of various degrees of ingenuity were brought forward to produce locomotion without the aid of adhesion at all. It was in 1813 that Mr. Blackett, of Wylam, had an engine constructed which worked by the adhesion of its wheels on the rails only. "His railroad was a plate rail, and would, consequently, present more friction or resistance to the wheels than an edge rail; and, on that account, the amount of adhesion would be greater than upon the latter rail. Still the credit is due to Mr. Blackett, for proving that the locomotion could be applied by that means alone." Since which time the contrivances for facilitating locomotion have been numerous and highly successful; and, in the hands of George Stephenson, Esq., followed by other scientific persons, the locomotive engine has become a wonderful machine, and promises, by its almost magical effects, to take a large share in improving the social, moral, and political condition of kingdoms. Two of the most modern construction are represented in Plates 77 and 78, of which the following are the particulars:—

Comet Locomotive Engine.—Plate 77 represents the 'Comet' locomotive, made by R. and W. Hawthorn, civil engineers, manufacturers of steam engines and machinery generally, of Newcastle-upon-Tyne, for the Newcastle and Carlisle Railway, being the first engine put upon this line. The cylinders are placed in a horizontal position, twelve inches diameter, and sixteen inch stroke. Wheels, four in number, four feet diameter, coupled by side bars. The crank pins are fixed in the wheels, having no outside frame. Boiler seven feet five inches long, three feet diameter, with sixty six brass tubes, seven feet nine inches and a half long, two inches exterior diameter. Fire box forty one inches wide, twenty-one inches and a half long, and thirty 3 eight inches above the grate, having thirty-seven feet and a half of radiating heat, and two hundred and sixty-nine feet of communication heat. The slides are worked by four fast eccentrics, first introduced into this engine by the manufacturers, instead of two loose ones heretofore used, and the complicated machinery for reversing the motion hereby materially simplified, and rendered much more secure, both as regards regularity of motion, and its being less liable to derangement, which, with further improvements upon this principle, have been invariably used by these gentlemen in their manufacture of other engines.

The 'Harvey Combe Engine,' Mr. Stephenson's Patent. Plate 78.

Cylinders	Diameter	12 inches.
	Length of Stroke	18 „
Tubes, 120 in Number.—Internal diameter		1¾ „
Wheels. . .	One Pair (driving wheels)	5 feet diameter.
	Two Pair	3 feet 6 inches.
Weight. . .	When empty, nearly	10 tons.
	Of water, fuel, &c.	1 ton 18 cwt.

Total evaporating surface about 480 feet superficial—estimated to be about 50-horse power.

We shall continue our notice in the next Journal.

On Warming and Ventilating, with Directions for making and using the Thermometer Stove, or Self-Regulating Fire, and other new Apparatus. By Neil Arnott, M.D. London: Longman and Co. 1838.

The system of warming and ventilating of buildings is becoming a matter of consideration by all classes. The old system of warming by open fire-places appears to be doomed to annihilation. Count Rumford was the first who called the attention of the public to the wasteful expenditure of fuel in the old-fashioned fire-places of his day, when it was considered a luxury to have a chimney large enough to allow a chair being placed on each side of the grate. By his numerous experiments and public illustrations, he led the way to reducing the opening to at least a third of the original size. He pointed out that the nuisance of smoky chimneys was principally owing to the large opening made for the fire-place, and the improper setting of the stove. He recommended the aperture to be both reduced in height and width, the angles contracted by bevelled or splayed covings set at an angle of 45°, the orifice of the flue to be made much smaller, the width not to exceed four or five inches, and the length not more than the width of the fire-place; and from these directions of Count Rumford were manufactured the "Rumford improved register stove." From this time, instead of the chimney breasts projecting into the room, in many cases a fourth of the width, they did not project more than about a foot. According to Dr. Arnott's experiment, it appears that even this contracted fire-place is much too large, and that there is no necessity for building chimney flues larger than one-fourth of the present size, and that the recess left in the chimney for the stove may be altogether abandoned. From the description given by the Doctor of his stove, and the great saving it will effect in fuel, we cannot but think that it will cause a complete revolution in the science of warming and ventilating of buildings. What can be a greater boon to the public than this invention? The poor of the metropolis, during the present winter, have suffered most severely from the cold, in consequence of the enormous price of fuel, owing partly to the monopoly of the coal-owners, and also to the severe frost which had blocked up the river Thames. According to Dr. Arnott's statement, the hovel of the poor may have a delightful degree of warmth kept up the whole of the day for the trifling sum of *one penny!* And whether the inhabitant be at home or abroad, the fuel may be kept ignited, so that after the toil of the day the poor artisan may return to his room already warmed for his reception. We have been led to these remarks on account of the numerous cases of privations which we have heard of during the present inclement season, and we think that it would be one of the greatest blessings to the poor if a society were established for the manufacture of these stoves upon an economical scale, and selling them to the needy at the prime cost, to be repaid by weekly instalments, and, in cases of known destitution, presenting or lending the same for the season; we feel convinced, that such a society would do more good than many of the numerous and excellent societies with which this country abounds. The stove, if manufactured on an extensive scale, and made plain and economically, would not cost more than a few shillings, the only part which requires any nicety of workmanship is the self-regulating valve.

We will now proceed to give a sketch of the great mass of information condensed in this treatise. The introduction points out the principal causes of disease in the human frame, and the necessity of a proper degree of warmth and ventilation, which are as requisite to the human race as food.

The object of this essay is to render the knowledge on the subjects of ventilation and warming which now exists among the learned, familiar to all, and to introduce to public notice new and simple means of securing the ends in view.

The following extract will be found useful:—

On Warming.—All animal bodies require to exist in a certain temperature, which in those called warm-blooded, is considerably higher than of the surrounding atmosphere; and by the actions of life they maintain in themselves that which to each is suitable. This continues very nearly uniform, notwithstanding considerable fluctuations in the temperature of the air, and of other objects around them. In man the animal heat is of 98 of Fahrenheit, whether under the burning sun of India, or amidst the snows of the Pole. The animal heat is maintained above lower surrounding temperatures chiefly by the function of respiration, in which the oxygen of the air received into the lungs, combines by a kind of slow combustion with carbon from the blood, and gives out heat, nearly as when oxygen and carbon combine in a common fire. This focus of heat suffices to maintain the healthy temperature even in a naked body, in air at from 60° to 70°, and in bodies clothed with fur or feathers, it will maintain that temperature in air which is very cold indeed.

* * It would be a good rule for persons in Europe to clothe themselves in winter so as to be comfortable in a room at a temperature of 60° or 62°, and to let that be the steady temperature of their common apartments, which it could then never be dangerous either to enter or to leave. Now, with common fires in England, rooms are often heated up to 70° or above, and cooled down to 50° or below.

Ordinary combustion is chemical union taking place with intense energy, productive of light and heat, between oxygen and some substance to which oxygen has strong chemical attraction. The substances which so combine with oxygen are called combustible, and of these the most common and cheapest are coal, wood, coke, charcoal, and peat. Of the heat produced in the combustion of coals, a proportion [rather less than half is radiated around the fire, as the light is from a fire or from a candle, and rather more than half combines with the air which feeds the combustion and rises with the smoke, to be dissipated in the atmosphere. Experiment has shown that

One pound of good coal	. . . . .	Melts of ice	.. 90 lbs.
— Coke	. . . . .	—	.. 84
— Wood	. . . . .	—	.. 32
— Charcoal of wood	. . .	—	.. 95
— Peat	. . . . . .	—	.. 19

indicating the comparative values of these substances as fuel,—and the exact relation is known between the quantity of heat required to melt ice, and to effect other results. The quantity of heat which raises the temperature of a cubic foot of water one degree, being called one, of such ones or units, 140 will melt a cubic foot of ice; 180 will raise the temperature of a cubic foot of water from 32°, or freezing, to 212°, or boiling temperature; 960 more will convert that into steam; and what heats a cubic foot of water 1°, will heat 2,850 cubic feet of common air also 1°, or half that quantity 2°, and so forth. One mode of estimating how much of the heat of a fire radiates around it, and how much combines with the smoke, is to let all the radiant heat melt ice in a vessel surrounding the fire, and all the heat of the smoke melt ice in another vessel surrounding the chimney. The two quantities of water thus obtained, and measuring the quantities of ice melted, prove the radiant portion of the heat to be in ordinary cases rather less than the combined, that is to say, to be less than half of the whole heat produced.

The treatise next explains the several modes of obtaining heat which have been adopted, and are as follows:—*A fire in the open air*, as still adopted by houseless savages; a *fire under cover*, by burning of wood or charcoal in the centre of the room. This barbarous mode was in use in some of our London Inns of Court within the last few years, and is still adopted in some of the large halls of the Colleges at the English Universities; and *the open fire under a chimney*.

This is the plan now generally used in England, and we shall therefore take the common open English fire as a familiar standard with which to compare other plans; and we shall moreover consider all the plans in reference to the great object sought by them, of obtaining everywhere on earth, at will, the temperature most congenial to the human constitution, such as exists in an English summer evening, and in air as pure as blows on any hill-top.

By an *open English fire* it is impossible to obtain in a room any temperature. The heat used is that portion only which radiates around with the light, while all that is in the smoke passes up the chimney. This radiated heat first warms the walls and other objects on which it falls, and these by contact with the air of the room then warm it. There are however serious disadvantages, which we shall now enumerate.

1. *Waste of fuel.*—We find that of the whole heat produced from the fuel used, about seven-eighths ascend the chimney, and are absolutely wasted. The loss of heat is, first, the more than half which is in the smoke as it issues from the burning mass. Secondly, that carried off by the current of the warmed air of the room, which is constantly entering the chimney between the fire and the mantelpiece, and mixing with the smoke. This is estimated at nearly two eighths. Thirdly, it is a fact that the black or visible part of the smoke of a common fire is really a precious part of the coal or wood escaping unburned. If then more than half of the heat produced be in the smoke, and nearly a fourth of it in the warm air from the room which escapes with the smoke, and if about an eighth of the combustible pass away unburned, there is a loss of at least seven-eighths of the whole. Count Rumford estimated the loss at still more; namely, fourteen-fifteenths.

Dr. Arnott then proceeds to point out other evils attending open fire-places, and which he considers are the causes of unequal heating at different distances from the fire—cold draughts, cold foot-bath, bad ventilation, smoke and dust, loss of time, danger to property, danger to person, expense of attendance, and, lastly, the necessity of having sweeping-boys. He then gives an account of the different systems of warming, and the evils attending each; first, the *common close stove*, commonly known as the Dutch stove.

There is, however, one disadvantage peculiar to the close stove, which countervails nearly all its good qualities, namely, that its very heated surface of iron acts upon the air which comes in contact with it, so as to impair exceedingly the air's purity and fitness for respiration. The air acquires a burnt and often sulphurous smell, in part, no doubt, because dust, which it often carries, is burned, and in part because there is a peculiar action of the iron upon the air. It becomes very dry, too, like that of an African simoom, shrivelling every thing which it touches; and it acquires probably some new electrical properties. These changes combined make it so offensive, that Englishmen unaccustomed to it cannot bear it. In this country many forms have been proposed, some of them gracefully designed, with transparent talc doors and other attractions; and they have been tried in rooms, public offices, passages, halls, &c., but have been afterwards very generally abandoned. Persons breathing the air heated by them are often affected by headaches, giddiness, stupor, loss of appetite, ophthalmia, &c. A north-east wind, which distresses many

people, bringing asthmas, croups, &c., and which withers vegetation, is peculiar chiefly in being dry.

In northern continental Europe, to avoid deteriorating the air by the overheating of the surface of an iron stove, it is now common to make close stoves and their chimneys of thick brickwork, either included in the walls, or projecting as a bulky mass into the rooms, the rooms being often covered with porcelain. These do not allow the heat of the fire to pass outwards so quickly as a metal stove, and hence their exterior does not become so much heated. The heated stove continues to warm the room long after the fire is extinguished, but of course with diminishing power. These stoves, as compared with an open fire, are very economical. An English gentleman once at St. Petersburgh, wishing to see there his old English fire, had an open chimney constructed, but found that with all it could do, and although the close stove also was plied as much as possible, and was lighted twice in the day instead of once, the room was much colder than before.

An economical mode, known in China, of using fuel to warm rooms, is to have the floors of tile, below which the hot smoke of a close fire passes.

In England, where such activity of thought prevails on all subjects interesting to humanity, and where, from the advancement of the arts generally, wants in relation to temperature arose which scarcely existed elsewhere—as in the necessity of heating factory rooms so large, that one fire was insufficient, and more than one were inadmissible—the imperfection of the open fire, and of the close stoves, having been strongly felt, other means were eagerly sought, and are now extensively used; namely, 1. Steam admitted to pipes or other vessels placed in the apartments to be warmed; 2. Hot water similarly admitted and distributed and circulating back to the boiler to be heated again; and 3, Heated air prepared in a separate place, and then distributed by various means over the building to be warmed.

The following calculations will be found useful for ascertaining the proper proportions of heating surface.

To determine the extent of surface of steam-pipe or vessel necessary to warm particular apartments, it was to be considered that the loss of heat from them occurs in three ways—1st, rapidly through the thin glass of the windows; 2dly, more slowly through the thick substance of the walls, floor, and ceiling; and, 3dly, in combination with the air which escapes at the joinings of the windows and doors, or at other openings purposely made for ventilation. Different writers and manufacturers have made very different estimates of the quantities of heat lost in these various ways, and as yet no exposition of the matters has been made with the accuracy which the subject deserves; but an intermediate estimate, as applied to common cases, may be shortly stated thus:—that in a winter day, with the external temperature at 10° below freezing, to maintain in an ordinary apartment the agreeable and healthful temperature of 60°, there must be of surface of steam-pipe, or other steam-vessel, heated to 200° (which is the average surface temperature of vessels filled with steam of 212°), about one foot square for every six feet of single glass window, of usual thickness; as much for every 120 feet of wall, roof and ceiling, of ordinary material and thickness; and as much for every six cubic feet of hot air escaping per minute as ventilation, and replaced by clod air. A window, with the usual accuracy of fitting, is held to allow about eighty feet of air to pass by it in a minute, and there should be for ventilation at least three feet of air a minute for each person in the room. According to this view, the quantity of steam-pipe or vessel needed, under the temperatures supposed, for a room sixteen feet square by twelve feet high, with two windows, each seven feet by three, and with ventilation by them or otherwise at the rate of sixteen cubic feet per minute, would be—

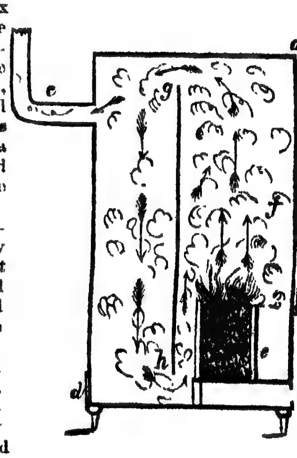
For	42 Square feet of glass (requiring 1 foot for 6)	7
	1,238 Feet of wall, floor, and ceiling (requiring 1 foot for 120)....	10⅓
	16 Feet per minute, ventilation (requiring 1 foot for 6)........	2⅔
	Total of heating surface required	20

which is twenty feet of pipe four inches in diameter, or any other vessel having the same extent of surface, as a box two feet high, with square top and bottom of about eighteen inches. It may be noticed that nearly the same quantity of heated surface would suffice for a larger room, provided the quantity of window-glass and of the ventilation were not greater; for the extent of wall, owing to its slow conducting quality, produces comparatively little effect.

A heated surface, as of iron, glass, &c., at temperatures likely to be met with in rooms, if exposed to colder air, gives out heat with rapidity nearly proportioned to the excess of its temperature above that of the air around it, less than half the heat being given out by radiation, and more than half by the contact of the air. Thus one foot of iron pipe of 200° external temperature in the air of a room at 60°, the difference between them or excess being therefore 140°, gives out nearly seven times as much heat in a minute as when its temperature falls to 80°, reducing the excess to 20°, or a seventh of what it was. If window-glass, therefore, cooled at the same rate as iron plate, one foot of the steam-pipe iron would give out as much heat as would be dissipated from the room into the external air by about five feet of window, the outer surface of which were 30° warmer than that air. But, because glass both conducts and radiates heat in any case about one-seventh slower than iron, the external surface of glass of ordinary thickness, forming the window of a room heated to 60°, would, in an atmosphere of 22°, be under 50°, leaving therefore an excess of less than 30°; and about six eet of glass would be required to dissipate the heat given out by one foot of he iron steam-pipe. Through double windows, whether consisting of two sashes, or of double panes half an inch apart in the same sash, the loss of heat is only about a fourth part of what takes place through a single window. Then, it is a fact ascertained by experiment, that one foot of black or brown iron surface, the iron being of moderate thickness, with 140° excess of temperature, cools in one second of time 156 cubic inches of water, one degree of Fahrenheit's thermometer. From this standard fact, and the law given above, a rough calculation may be made for any other combination of time, surface, excess, and quantity. And it is to be recollected that the quantity of heat which changes in any degree the temperature of a cubic foot of water, produces the same change on 2,850 cubic feet of atmospheric air.

We now come to the most important part of the treatise, which describes the *self-regulating fire*, or *thermometer-stove*. The Doctor first enumerates the difficulties he had to contend with in obtaining a stove to meet all the requisites of properly warming his library, which ultimately led to the construction of a stove, which he thus describes :—

The object sought was now clearly seen to be, merely to place in any apartment the required extent of metallic surface, kept steadily at a temperature not exceeding 200° of Fahrenheit. It evidently was of no importance what hot fluid filled or warmed the vessel—whether water, steam, oil, or air, or whether there were an included fire—provided the temperature of the surface was maintained; for the box in any case would be quite close, permitting no escape of its contents. If, therefore, in a box of the required size, a fire could be placed so as to warm the box with perfect uniformity all around, while the fire itself were so controlled by a self-acting regulator, that it should burn always exactly as fast as was required to keep the box steadily at any desired temperature, the object sought would be attained, and there would be many concomitant advantages of cheapness, simplicity, &c. These words have sketched the *Self-regulating Fire, or Thermometer Stove*, of which the form first tried is now to be described more particularly by aid of the woodcut.



The outline *a b d c* represents a box formed of sheet-iron, and divided by the partition *g h* into two chambers, communicating freely at the top and bottom. The letter *e* marks the fire-box or furnace, formed of iron, lined with fire-brick, and resting on a close ash-pit, of which *b* marks the door, and near which door there is a valved opening, by which air enters to feed the fire when the door is shut; *i* marks the door of the stove by which fuel is introduced, *c* is the chimney-flue. While the stove-door and ash-pit door are open, a fire may be lighted, and will burn in the fire-box just as in a common grate, and the smoke will rise and pass away by the chimney, mixed with much colder air rushing in by the stove-door; but if the stove-door and ash-pit door be then closed, and only as much air is admitted by the valved opening in the ash-pit as will just feed the combustion, only a small corresponding quantity of air can pass away by the chimney, and the whole box will soon be full of the hot air or smoke from the fire circulating in it, and rendering it every where of as uniform temperature as if it were full of hot water. This circulation takes place, because the air in the front chamber around the fire-box, and which receives as a mixture the red-hot air issuing from the fire, is hotter, and therefore specifically lighter than the air in the posterior chamber, which receives no direct heat, but is always losing heat from its sides and back; and thus, as long as the fire is burning, there must be circulation. The whole mass of air is, in fact, seen to revolve, as marked by the arrows, with great rapidity; so that a person looking towards the bottom of the stove through the stove-door *i*, might suppose, if smoking uel had been used to make the motion visible, that he was looking in at the top of a great chimney. The quantity of new air rising from within the fuel, and the like quantity escaping by the flue *c*, are very small compared with the revolving mass. There remains to be noticed only the thermometer regulator of the combustion. Many forms presented themselves to my mind, as described in the section on the manufacture of the stove, any one of which will close the air-passage, slackening or suspending the combustion at any desired degree, and will open it again instantly, when the temperature falls below that degree.

I had thus a simple box of iron, of cheap and easy construction, answering all the purposes of expensive steam or hot-water apparatus, burning its fuel as steadily and as regularly as an argand lamp burns its oil, or as an hour-glass lets its sand run through, and allowing me, by merely touching a screw on the thermometer, rapidly to increase or diminish its heat, as by touching another regulating screw we increase or diminish the light of a lamp.

What chiefly surprises a stranger in this new stove, is the very small quantity of air required to support the combustion which warms a large room; the whole might enter by an opening of half an inch diameter, and the quantity of air or smoke which passes into the chimney is of course proportionally small. These facts at once suggest how small the consumption of fuel must be, as that depends on the quantity of air entering, how perfect the combustion of the fuel must be where so little is expended, and how completely the heat produced in the combustion must be turned to account. The combustion is so perfect, because the fuel is surrounded by thick fire-brick, which confines the heat so as to maintain intese ignition; and the

saving of heat is proved by the rapidly diminishing temperature of the flue, detected by a hand passing along it from the stove. During the winter 1836-7, which was very long and severe, my library was warmed by the thermometer-stove alone. The fire was never extinguished, except for experiment or to allow the removal of pieces of stone which had been in the coal, and this might have been prevented by making the grate with a moveable or shifting bar. The temperature was uniformly from 60° to 63°. I might have made it as much lower or higher as I liked. The quantity of coal used (Welch stone-coal) was for several of the colder months, six pounds a day—less than a pennyworth—or at the rate of half a ton in the six winter months. This was a smaller expense than of the wood needed to light an ordinary fire, therefore the saving was equal to the whole amount of the coal merchant's ordinary bill. The grate, or fire-box, fully charged, held a supply for twenty-six hours.

The thermometer-stove, as compared with other modes of warming, will be best understood, by reviewing its chief qualities. A general expression for them is, that it possesses all the advantages of steam or hot water warming, with many advantages peculiar to itself.

1. *Economy of fuel.*—We have seen, at Art. 18, that a common open fire wastes seven-eighths of the heat produced. This stove saves or puts to use very nearly the whole, because, first, it does not allow the air which has fed the combustion to escape, until deprived of nearly all the heat; and, secondly, it does not allow any of the warm air of the room, except the little which feeds the fire, to escape through the chimney. Marking, strikingly, how the heat produced in the stove is applied to use, we find that a sheet of paper set fire to, and put into a cold stove, will warm the whole almost as if boiling water had been poured into it, and the heat is afterwards all diffused in the room. The same sheet of paper burned under the chimney of an ordinary grate, would produce no sensible effect in the room. The ascertained fact respecting the expenditure of the stove is, that an eighth of the fuel which is needed for a common fire suffices; and stone-coal, or anthracite, coke, and even cinders—in a word, the cheapest fuel—answers better than that which is dearer. Thus, since bituminous coal has become so precious, as the gas-giving material for common lights—the remnant of it, after the gas is taken away, has also acquired a new value.

The Author then proceeds to explain the other advantages of his stove—uniform temperature in all parts of the room and throughout the day, the stove is always alight, no smoke, no dust, no danger to persons or property, obedience to command, trifling original expense, small expense of attendance upon it, it is easily moved, may be made of a graceful form, it is a good cooking-stove, no sweeping-boys are required,

The advantages hitherto enumerated of the stove in its domestic bearing, might be otherwise classified under the heads of economy of fuel—economy of original expense—economy of service economy of comfort—economy of health and of life—economy of furniture and property generally—and economy of time.

The principles embodied in Dr. Arnott's stove are evidently described by Count Rumford, in his "Essays on the Management of Fire and the Economy of Fuel, as follows :"—

"Though it is not known exactly how much heat it is possible to produce in the combustion of any given quantity of any given kind of fuel, yet it is more than probable that the quantity depends in a great measure on the management of a fire. It is likewise probable, I might say certain, that the heat produced is furnished, not merely by the fuel, but in a great measure, if not entirely, by the air by which the fire is fed and supported. It is well known that air is necessary to combustion; it is likewise known that the pure part of common atmospheric air, or that part of it (amounting to about one-fifth of its whole volume) which alone is capable of supporting the combustion of inflammable bodies, undergoes a remarkable change, or is actually decomposed in that process; and as in this decomposition of pure air, a great quantity of heat is known to be set loose, or to become redundant, it has been supposed by many (and with much appearance of probability), that by far the greater part, if not all the heat produced in the combustion of inflammable bodies, is derived from this source.

"But whether it be the air, or the fuel, which furnishes the heat, it seems to be quite certain that the quantity furnished depends much upon the management of the fire, and that the quantity is greater as the combustion or decomposition of the fuel is more complete. In all probability, the decomposition of the air keeps pace with the decomposition of the fuel.

"It is well known that the consumption of fuel is much accelerated, and the intensity of the heat augmented, by causing the air by which the combustion is excited to flow into the fire-place in a continued stream, and with a certain degree of velocity. Hence, blowing a fire, when the current of air is properly directed, and when it is not too strong, serves to accelerate the combustion, and to increase the heat; but when the blast is improperly directed, it will rather serve to derange and to impede the combustion than to forward it; and when it is too strong it will blow the fire quite out, or totally extinguish it.

"Fire-places may be so constructed that the fire may be made to blow itself, or—which is the same thing—to cause a current of air to flow into the fire; and this is an object to which the greatest attention ought to be paid in the construction of all fire-places where it is not intended to make use of an artificial blast from bellows for blowing the fire. Furnaces constructed upon this principle have been called air-furnaces; but every fire-place, and particularly every closed fire-place, ought to be an air-furnace, and that even were it intended to serve only for the smallest saucepan, otherwise it cannot be perfect. * * *

"By surrounding the fire on all sides by a wall, the cold atmosphere is prevented from rushing in laterally from all quarters to supply the place of the heated air or vapour, which, in consequence of its increased elasticity from the heat, continually rises from the fire, and this causes the current of the air below (the only quarter from which it can with advantage flow into the fire) to be very strong.

"But in order that a fire-place may be perfect, it should be so contrived that the combustion of the fuel, and the generation of the heat, may occasionally be accelerated or retarded, without adding to or diminishing the quantity of fuel; and, when the fire-place is closed, this may easily be done by means of a register in the door, which closes the passage leading to the ash-pit;—for, as the rapidity of the combustion depends upon the quantity of air by which the fire is fed, by opening the register more or less, more or less air will be admitted into the fire-place, and consequently more or less fuel will be consumed, and more or less heat generated in any given time, though the quantity of fuel in the fire-place be actually much greater than what otherwise would be sufficient.

"In order that this register may produce its proper effect, a valve, or a damper, as it is commonly called, should be placed in the chimney or canal by which the smoke is carried off; which damper should be opened more or less, as the quantity of air is greater or less which is admitted into the fire-place. This register and this damper will be found very useful in another respect—and that is, in putting out the fire when there is no longer an occasion for it; for, upon closing them both entirely, the fire will be immediately extinguished, and the half-consumed fuel, instead of being suffered to burn out to no purpose, will be saved.

"Nearly the same effects as are produced by a damper may be produced without one, by causing the smoke, after it has quitted the fire-place, to descend several feet below the level of the grate on which the fuel is burned, before it is permitted to go up the chimney.

Dr. Arnott next proceeds to make some judicious remarks on ventilation, which we must defer noticing for another opportunity: he then points out the advantages of his stove for the purpose of *warming and ventilating an ordinary sitting-room.*

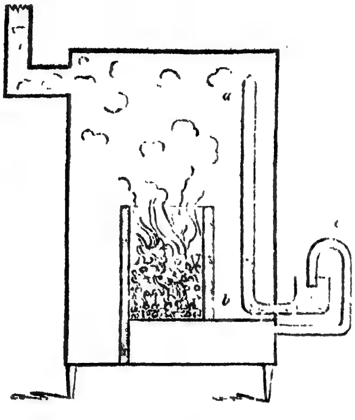
Warming and ventilating an ordinary sitting room.—An ordinary sitting-room, or any apartment of moderate size, occupied by a family of a few persons, will be easily warmed by one thermometer-stove, of dimensions calculated by the rule given at Art. 37. The stove gives out its heat partly by radiation all around it, but chiefly by warming the air which touches it. This air then ascends, and spreads over the ceiling, warming that, and soon by downward radiation from the ceiling, and farther motion and mixing of the air, from the descending currents produced, because the walls absorb the heat of the air which touches them, the whole room is more or less equably warmed. The difference of sensation experienced by a person entering a room heated to a certain thermometric degree by a stove, and a room heated to the same degree by an open fire, depends on the air being somewhat warmer, and the walls somewhat colder, in the first room than in the second. A small stove at a high temperature, gives out as much heat as a large stove at a low temperature; but there are great advantages in using a stove of full size—as, that its moderately heated surface cannot injure the air of the room— that there is economy of fuel, because the air leaving it towards the chimney carries less heat to waste, and that it acts more steadily from being less quickly either heated or cooled.

Sufficient ventilation for an ordinary sitting-room will be ensured, in a cold winter day, 1st, by the demand of air for the combustion in the stove; 2ndly, by the considerable change occurring through the crevices around doors and windows, which may be taken at about six cubical feet a minute for each; and, 3rdly, by the hundreds of gallons of fresh air, which, every time the door is opened, enter and displace an equal quantity of the air previously in the room. In warmer weather, when the difference between the external temperature and that of the room is less, and there is, therefore, less tendency to spontaneous change, some additional means may be used from among those to be described hereafter.

These remarks are followed up, showing how the stove may be adapted for warming and ventilating a suite of rooms, a very large room, school-rooms, concert or assembly-rooms, courts of law, churches, houses of parliament, theatres, and other buildings. Directions are given for *manufacturing, fixing, and using the thermometer-stove,* which may be easily understood by any workman.

A great object sought in the construction of the stove was, that when the stove reached any desired degree of temperature, there should be, in or about it, a thermometer capable not only of indicating the degree of temperature

reached, but also of doing the work of moving a valve to check the admission of air, whenever the heat were at all above the degree desired, and of increasing the admission when the heat fell below that degree.



This cut exhibits, perhaps, the simplest form of the expanding air regulator; *a b c* is a bent glass tube, closed at *a*, and open where it is cup-shaped at *c*. The bottom part, *b c*, has mercury in it. The part *a b* is placed within the stove. Over the cup *c*, and dipping into it, is the mouth of the tube, which admits air to the stove. When the stove is heated, the expanding air in *a b* depresses the mercury in *b*, to raise it in *c*, until it approaches or reaches the mouth of the air-tube, and so arrests the entrance of air. In this form there is no moving part or friction, but in the rising fluid, the surface of which is, in fact, the valve plate or stopper, and it cannot fail to act. Common oil would serve in it nearly as mercury, rendering the apparatus very cheap. To enable persons by this regulator to fix the heat of the stove at any desired degree, the mouth of the air-tube *c* is made to slide or screw up and down, so as to be approached by the fluid at a higher or lower degree of heat.

There is much valuable matter connected with the philosophy of warming and ventilating of buildings to be found throughout the treatise; it is a work which ought to be in the hands of every member of the profession.

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS, No. 3.

THE ROYAL EXCHANGE.

The fire which happened on the night of the 10th of January, and of which such flaming accounts served for nearly a week afterwards to fill the newspapers, leaves me no choice of subject for this number. Not to speak of that "splendid edifice," as the newspapers have been pleased to style it, would be turning from my door a very good chance of being read; because, although nobody perhaps would have cared at any other time to learn my opinion of such a stale, antiquated pile, it has now all at once—thanks to the chapter of accidents—become a remarkably attractive and interesting subject! That the late Royal Exchange was *splendid* I do not deny, provided I may be allowed to limit its claim to such epithet to one particular occasion—namely, when it was all in a blaze. Splendour at any other time it was never my good luck to detect in it; on the contrary, I could never help fancying that its newsvenders' shops, and others with which its exterior was blocked up below, gave it a very pedlar-like appearance.

However, before I proceed to examine and cross-question the building, let me call into court one who has something to say as to its general character; a no less respectable and worthy personage than my own predecessor—my literary ancestor by my own voluntary adoption—namely, Ralph the First, or as my title would indicate him to be, Ralph the Defunct. Well! what does he say?—"Upon the whole, the entrance into this building is very grand and august. The two statues which adorn it are in a particular manner beautiful and admirable; but then the tower,"—he is speaking, gentlemen, of the former tower—"which arises over it, is a weight to the whole building, and is at the same time broken into so many parts, that it rather hurts than pleases, and if reduced to one-half of its present height, would harmonize abundantly better with the whole. The inside is light and airy,"—troth! he may well say airy, since there was nothing to keep out either air or weather,—"laid out in a very good style, and finished with great propriety of decoration. I could wish, though, either that the statues were executed in a better manner, or that the City would condescend to excuse setting up any more, for nothing can be more ridiculous than to hurt the eye with a fault in the affectation of beauty."

Ralph the First, you may now retire, and make way for Ralph the Second. Well, now that we have heard what old "Squaretoes" had to say, let us sift the matter, and begin by looking at that front, whose entrance he has pronounced to be "very grand and august." And so, truly, is my Lord Mayor's state-coach; but then, as Squaretoes himself says, its grandeur is of that awkward, floundering, cumbersome, old-fashioned shape, that people are apt to laugh at it.

Nothing is more easy than to apply some magnificently laudatory epithet to the edifice here noticed, for ready-made commendation may be got at out of any history or picture of London; the difficulty is to show that it is awarded by good taste and sound criticism, which is what the books in question never attempt to do, neither can I at all assist them. In my opinion *bizarre* would be by far a more appropriate title for it, for the Royal Exchange might convince the most sceptical, notwithstanding Sir Christopher's maxim, that architecture does not admit of fashions, there have been very whimsical fashions in it ere now. This is attested by more than one of Wren's own buildings, even without giving him the "credit" of the design for this, which has been claimed for him by a writer in the Gentleman's Magazine (December, 1827), after Mr. Brayley had taken some pains to show that it rightfully belonged to some city surveyor, named Jerman. In the scale of criticism, it matters not one grain whether it was Wren or any one else who was the author of the design; therefore the reader shall not be bored here with any discussion relative to that minutely interesting point, my business being with the design itself. And, first, for the Cornhill front: this was not according to the original design (which may be seen in Campbell's Vitruvius Britannicus), having undergone a good deal of alteration; and some one, I find, has been altering it since the fire, giving what it never had before, namely, "a tetrastyle portico"! so at least the "Mirror" describes it, owing, perhaps, to some odd metamorphosing power it possesses in reflecting objects.

In its first shape this front had, besides a spire-like tower of three stories, the lowermost of which contained a mullioned window, forming two arched openings with a circular compartment above them, an ugly tall lantern, covered with a bell-shaped roof at each extremity of the part projecting from the main building. These last had been removed altogether, and the tower was taken down and rebuilt some years ago, after a design by Mr. George Smith, which, although not without a certain degree of heaviness, partly occasioned by there being arched windows between the columns, was in better taste than the original structure. At the same time this centre compartment of the front was pruned of some of its excrescences, by taking away the barbarous semicircular pediment which used to be over each of the side intercolumns adjoining that containing the large central archway, which, independently of their uncouth form, gave the middle intercolumn the appearance of being a mere space coming in between two compartments, each consisting of two columns, crowned by the aforesaid pediments, and thus cut up the whole into three distinct portions.

The removal of these disfiguring excrescences helped to render this centre division of the front somewhat more connected, although owing to the entablature not being continued in an unbroken line over the four columns constituting the larger order, but carried only over the side intercolumns, and receding above the middle one, the want of continuity was here more observable than agreeable. After all, this was a trivial blemish, in comparison with the lumpish taste which displayed itself in the decoration, as we suppose it must be termed, of the intercolumn on each side of the centre one. Here, instead of the rustic surface of the wall being continued throughout the whole space, it was carried only a little way beyond the columns, so as to form wide piers, against which the columns were placed, and into the interval between these piers was crammed an ill-proportioned doorway below, with a broken scroll pediment coming against the pedestal of a niche with diminutive columns, and surmounted by a pediment somewhat similar to that of the doorway; and lastly, cutting into this second pediment was a small circular window. Thus doorway, niche, and window, were piled up one on the other, so as to produce one of the most heterogeneous jumbles in the very worst mode of Italian architecture. All this was so glaringly bad, that at the present day the veriest novice would have been heartily ashamed of such a patchwork medley; at the same time, the remedy for it was easy enough, nothing more being required than to cut away all that architectural farrago, and either make these lateral intercolumns quite solid, and continue the rusticated surface; or, if there must be doorways to enlarge them, giving them a handsome entablature, whose cornice would have continued the line of the impost of the centre arch; and the space above might have very well been filled up entirely with large bassi-relievi, in which situation the sculpture could have been far better discerned than in the panels of the attic behind the balustrades, and attached to the lower part of the tower. Had this been done, the line of the impost to the great arch would have been carried uninterruptedly throughout the whole front, because in the parts on either side of the centre it formed the cornice to the arcades. Yet if thus far the original design admitted of being corrected with very little trouble or expense, there were radical vices in it, which bade defiance to any kind of amendment short of recomposing the whole façade; because the capitals of the larger order did not even rise up to those of the smaller one above

the arcades on each side of it, so that the centre appeared to be depressed in comparison with the parts adjoining it, at least as far as the respective orders addressed themselves to the eye; whereas, the lower edge of the architrave of both orders should have been on the same level, or better still, the entablature of the larger one should have entirely cleared that of the other. Even when we come to examine the lesser order by itself, there is much to censure in its application, not that I intend to object very strictly to the liberty taken in grouping each column with two half pilasters, since that was by no means the most objectionable liberty taken by the architect; on the contrary, while it produced some degree of richness, it served in some degree also to narrow the intercolumns, and to make them not appear extravagant when measured by the breadth of the cluster composed of column and pilaster combined. Still, notwithstanding this artifice, for such we may allow it to have been, the intercolumns were nearly as wide as they were high. This was bad enough; yet it might have been partially remedied—rendered a degree less offensive, had the windows been somewhat tolerably proportioned, not to the width, but to the height of the spaces they occupy; whereas, by being made broad and low, though their large apertures rendered the part above the arcades actually less heavy than would have been otherwise the case, they had in themselves an air of clumsy heaviness, the very reverse of what is understood by *lightness* in the æsthetic import of the term. Nor was the offensive heaviness which here manifested itself at all lessened by coming immediately in contact with the arcades below, which were as strongly marked by the opposite character; and, except that the piers were rather too slender, these last-mentioned portions were the least exceptionable of any in the whole design. The shops within them certainly did not anywise contribute to architectural effect; let us therefore hope that the omission of them will be made a *sine qua non* in the instructions to architects for the new edifice. In regard to the north front, I shall merely observe, that it was many degrees inferior to the other, much more lumpish and deformed, and crammed in places with ugly little circular and oval mezzanine windows. It had, too, a very bad opposite neighbour in the Bank, the style of whose architecture did not act as a foil to set it off to the best advantage. For the matter of neighbourhood, however, the Bank itself had no great reason to be better pleased with the Exchange, since the latter building obtruded itself upon it very awkwardly and disagreeably. Of course, the want of parallelism between the two buildings will now be remedied, much to their improvement, and that of the street between them.

The interior of the Exchange may be soon dispatched. It was, in my eyes at least, nothing more than a dismal court, in a style of architecture for which hideous would be hardly too harsh a term. In its ornaments it had all the littleness and confusion ascribed by some to those of Gothic buildings, without their homogeneousness, and their propriety or their effect. Bookmakers, and critics of the Squaretoes school, assure us that it was adorned with two orders, Doric and Ionic; and truly there were Doric columns, and, if we looked narrowly enough, we might discern, stuck up at intervals, "few and far apart," certain diminutive stripes on the wall, that might pass for pilasters, and, in the imagination of some, for Ionic ones. In such matters, imagination will undoubtedly do a great deal, and enable us to see, like Polonius, what is "very like a whale indeed!" To describe all the odd whims and caprices here jumbled up together, otherwise than by means of a drawing, would be quite impossible; neither can I refer to the "Vitruvius Britannicus" as supplying an accurate delineation of this part of the structure; because, like many architectural works since its time, that is exceedingly sparing of sections, and has not given one of the Royal Exchange, unluckily, perhaps, for our curiosity, yet luckily enough for the reputation of the building itself and its panegyrists. Suffice it then to say, that there was no lack of finery. There were curved pediments filled up with dabs of festoons clapped about circular windows, and an abundance of small oval windows, placed so as to cut through both the architrave and the frieze of the upper entablature!! After this last remark, I need make no further comments on the taste that was there displayed; and it may, perhaps, serve to moderate the somewhat unphilosophical lamentations and bewailings of those whose pathos and patriotism combined have endeavoured to persuade us that the late "awful conflagration" has bereft us of a pile of such superior grandeur and beauty, that we ought to despair of beholding aught that can in any degree rival it. After all, I should be loth to destroy any body's pleasing illusions in regard to the Royal Exchange, or any other building upon which I may offer my remarks. I do wish, however, that those who are so exceedingly lavish of their praise in the lump, would not be quite so sparing of their ink, but condescend to edify such obstinate blockheads as myself, by pointing out, one by one, the beauties their more fortunate eyes are able to detect and discern.

NEW INVENTIONS.—No. 2.

BY PHILOTECHNICOS.

We are always pleased to hear of artists devoting their time and attention to the study of that branch of the arts that is considered by many of them to be derogatory to their calling;—we mean the art of decoration, as applied to the ornamenting of the interiors and exteriors of buildings. How this false pride arises we cannot imagine; for what is the tendency of all their works but to this particular end? Are they not now applied to the decoration of galleries and drawing-rooms, or to the closet of some great collector, dealer, or virtuoso? Where is the vast difference of pictures being hung up upon walls and bedizened with gaudy frames, or painted on the very panel or wall of the room itself? Where is this mighty degradation, where this *infra dig.*, that should so humble the aspiring knight of the pallet, that he will not deign to apply his talent to "the art of decoration?" Is it in the application of his utmost skill and ability to the adornment of a ceiling, or an altar of a church, or the grand staircase of a public building, or of the walls of a sumptuous palace or splendid mansion? Are not these frames much more costly and magnificent than a mere gilded border? Not that we would detract for a moment from the merits of the many beautiful creations of poetic fancy that are daily produced—far from it; our desire is only to uphold the superior nature of this particular employment, and a wish to see it much more encouraged than it now is; and we hope, by the dissemination of the enlightened policy of the present day, to see these false barriers cleared away, and the road again opened for the honourable reception of the "great men" of this talented age. Is not the name of a "Raffaelle" a sufficient guarantee for the high character this employment once assumed, when his principal, nay, his very best works, were produced when exercising the art of decoration; neither did a Michael Angelo, Rubens, Titian, Leonardi di Vinci, the Caracci, Paul Verenisi, and a whole host of other great painters, think it beneath *their* dignity to employ their time and talent to this particular art; but we need not go so far back for examples, when the name of Thornhill stands, in England, pre-eminent for his works, which now remain as a *memoria menti* of the perfection that the art in this country had once attained.

The beautiful ceiling of the Banquetting House, now Chapel, at Whitehall, by Rubens; the grand staircase of the British Museum, by De la Fosse; the dome of St. Paul's and the walls of Greenwich Hospital, by Sir James Thornhill; and many other public buildings, need only be noticed to support the importance of the art of decoration.

We have been led to make these remarks, by having lately seen the productions of many talented men devoted to this particular branch, which we propose to introduce, through the "Journal," to the professional and scientific reader, hoping thereby to be the means of extending its introduction and use throughout this improving country. We will commence with the works of Mr. Latilla on

Fresco Painting.

This kind of painting is most admirably adapted for the decoration of public buildings as well as of private dwellings; heretofore, the profession have been baffled in recovering the art of fresco painting, that has, for many ages, been almost in abeyance; but, thanks to the perseverance of Mr. E. Latilla, it is again revived, and we hope, ere long, to see the ceilings and walls of our many public and private edifices brilliantly illumined with this beautiful and lucid style of colouring.

Fresco is much superior to oil for large surfaces; the latter has a heavy appearance, and requires powerful varnish to bring it out, creating a glare and reflection of light which impede the sight, and render it impossible to view it, except at certain angles of vision. Its durability is, moreover, comparatively short, and it is but with great difficulty and judgment that it can be made to retain its richness of tone and colour. Fresco, on the contrary, as is proved by the beautiful works of the ancients in Pompeii, Herculaneum, and elsewhere, and by the master pieces of art of Raffaello, Corregio, and Michael Angelo amongst the Italians, has none of these disadvantages, while it is far richer in tone, more brilliant in colour, and will endure for ages.

Mr. Latilla appears to have long studied the art of fresco painting, and has produced many very beautiful imitations of the arabesque, Louis Quartorze, and Elizabethan styles, and is now training several clever young artists to assist him in producing works which, we hope, will ultimately vie with the splendid productions of early days.

The plan adopted by Mr. Latilla is to prepare a ground with two or three coats of colour, in a similar manner to that recommended in one of the early numbers of the "Journal," which we are happy to have been the means of communicating, namely, by using a roller covered with felt. The machine Mr. Latilla used was exactly similar to a child's toy, the little garden-roller, being about eight inches long and two inches diameter, with a long handle. This rolled over each coat in succession, after being painted in the usual way with a brush, produces a beautifully smooth surface, without the least appearance of the brush marks. We strongly recommend the adoption of this simple method for the painting the walls of staircases, dining-rooms, &c., which is so much superior to the old method, and so easy in its application, that were it once adopted, we are persuaded no man of taste will ever adopt any other. After thus preparing the walls of the required tint, he divides them into compartments by pilasters, enriched on the face with arabesque, or other foliage; and in the centre of each compartment he introduces a picturesque landscape and figures, or an allegorical subject. The ceiling he enriches with a foliaged border and angular ornaments, and, in the centre, with an aerial figure or centre flower. There are various other methods of decorating the rooms, either by forming panels on the walls, or festooning the upper part with fruit and flowers, or by introducing trophies and other ornaments, according to the taste of the owner or style of the

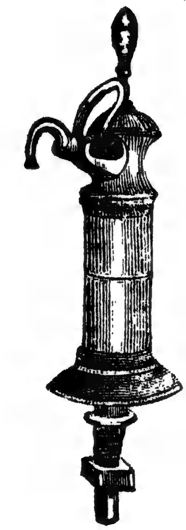
building; but, generally speaking, we would advise the greatest latitude to be given to the artist, who, by long study, ought to be best acquainted with the proper taste and style required.

Mr. Latilla has fitted up a room in this style at his residence in Howland-street, which he exhibits to all who are desirous of a better acquaintance with this kind of decoration. We have seen it, and recommend others to do the same, as it will convey some idea of the perfection that may be attained, where the means are not too limited; though for small houses a neatness, nay, elegance may be attained, at a comparatively trifling cost, the price not being much more than best paper-hanging, or graining. For old wainscotted rooms, it is by far preferable to the present heavy and monotonous method of painting, as the panels may be beautifully ornamented in fresco with foliage or landscape, and the styles and rails enriched in arabesque. We shall conclude this notice by advising the profession to examine into the merits of fresco painting, and to introduce it where such an opportunity occurs, being convinced that it only needs to be seen, to be admired. We wish Mr. Latilla and his pupils full success, and shall do our best, by reverting again to the subject as occasion may require, to assist him in his enterprising career.

Since writing the above remarks, I am informed that Mr. Ward is engaged to paint an historical subject for the ceiling of a room for Earl de Grey; that Mr. Paris is now employing his great taste and ability to the decoration of the Great Western Steam Ship, which is to be finished in a very superb manner; and that Mr. Eastlake painted, some time since, some rooms in the Herculaneum and Pompeian styles, for B. Kerr, Esq., in the Regent's Park; thus again are we gratified to hear of three eminent men lending their aid to the art of decoration.

We will now change our subject by running over a long string of new inventions, and select one or two, that may be considered as novelties.

Stocker's Patent Hydraulic Machine.



This machine consists, as represented in the annexed engraving, of a neat brass cylindrical standard, 13 inches high, and 2½ inches in diameter, and is intended as a substitute for the common beer machine, and is particularly applicable to dressing-rooms, where the cistern is in a lower story. It is small, simple, and ornamental. For taverns it will be found very useful for drawing beer or spirits, or for water to supply the counter or washing-stand. The stroke is regulated to draw exactly half or a whole pint at one pull; and every part of it can be unscrewed to clear out any dirt or other obstacle that may have got in, particularly the lower valve, which can be easily taken out, wiped, and replaced. It requires no stuffing-box, as the present beer-machines do; it is easily fixed to a counter or wash-hand stand, and is attached to a ferrule (previously soldered to the pipe) by a union nut and screw, and can be as easily removed.

Warming and Ventilation.

The number and variety of schemes for accomplishing this object is almost incredible. We have witnessed many of very original character, which is naturally to be expected, when we know that most of the scientific and learned men, as well as those of good practical knowledge, are all hot upon the subject, and are daily rivaling each other in producing their bright ideas to illumine the public mind upon this all-absorbing topic, which the several names of Arnott, Joyce, Perkins, Bramah, Price, Thompson, Cottam and Hallen, Ure, Sylvester, Hood, and many others whose names are familiar to your readers, will fully testify. Those possessing the most novel features, are the productions of the two first named, Dr. Arnott and Mr. Joyce. The stove invented by the former we will but merely notice, as having seen and admired it, for doubtless you will better describe its valuable properties in a review of the Doctor's work lately published upon the subject. With regard to Mr. Joyce's apparatus, which we have lately seen, it having been exhibited at the Institutes of Civil Engineers and of the British Architects, we will briefly describe, for the information of those readers who may have not yet seen it. It is of an upright cylindrical form, of bronze, with an ornamental top and tripod stand; a band encircles the middle, to which two handles are attached. The whole is very much in the form of an old-fashioned upright coffee urn. A small pipe admits air from the bottom, which passes through the fuel, and escapes by a valve at the top: this valve can be so regulated by raising or depressing it, as to create any degree of heat; but the heat generally required is about 400°, radiating from the sides, and to which, on applying a piece of paper, it will scorch, but not ignite. This apparatus, the inventor states, he has constantly used in his bed room, without experiencing the slightest inconvenience or any ill effects from the combustion of the fuel, which does not contain any deleterious qualities: the invention is the result of fourteen years' continued experiment, and he has only been prevented heretofore (like many others of his class) from obtaining a patent for want of pecuniary aid. Many have been the conjectures upon the nature of the fuel used, and many experiments have been tried by practical men to obtain similar results. Among the materials experimented upon are coal, coke, charcoal, ashes, and turf, with admixtures of lime, salt, saltpetre, and vitriolic acid, in various proportions and mixed in a variety of ways, and many valuable results have been the consequence. The fuel, we understand, is vegetable charcoal, so prepared as to give out no carbonic acid gas; but the way in which the inventor accomplishes this, he still withholds from the public: his plea is, that he has not yet quite secured his foreign patents—it would have been much better had he secured them before he exhibited his invention to the public. I would advise him not to lose much more time, or he will certainly, ere long, have many formidable rivals to compete with: Dr. Arnott's stove is already in the field, for which there is a very great demand. The fuel for the apparatus is intended to be sold at various depôts throughout the kingdom; if so, we would recommend the greatest caution to be used to guard against its adulteration, and that it be sold in *sealed* cases, so as to prevent the possibility of agents adulterating it; nor should this suffice, for the consequence, if such were the case, might be fatal to the consumer, who should be prepared with some test to detect the presence of carbonic acid gas, by which he might be able to judge for himself whether the fuel be properly prepared.

PARIS.

Embellishments of the Place de la Concorde.—Nothing as yet has been determined upon—at least nothing authentic has yet transpired, in regard to the mode in which the area of Trafalgar Square is to be laid out and decorated; but perhaps some hints might be taken from the very extensive embellishments now in progress at the Place de la Concorde, under the direction of M. Hittorff. In the centre of this place, which extends about 1,200 feet north and south, between the Guarde Meuble and Rue Royale and the Seine, stands the Luxor Obelisk, the erection of which was conducted by M. Lebas, Ingenieur de la Marine. This antique monument will form little more than a single central point, in comparison with the numerous other objects that will shortly surround it; for it is intended to form a spacious avenue leading from the Rue Royale to the Pont Louis XVI., having two fountains, one on the side next the above-mentioned street, the other on that towards the bridge. These fountains will be upwards of seven metres, or twenty-two feet English high, and will each consist of two elevated vasques or tazze, the upper one of which will be three and a half metres (above eleven feet English) wide, and the other six metres. The first will be supported by three *genii*, with festoons of foliage between them, below which will be three swans spouting out water. The larger vasque will be sustained by six draped allegorical figures standing on the prows of vessels, that will appear to be immerged in the water received into the larger basin at the foot of the fountain. Between these six figures there will be as many dolphins, which, like the swans, will spout forth streams of water. In addition to these, there will be six other large figures in the basin, three representing Tritons, the rest Nereides; so that altogether there will be fifteen statues, besides swans, dolphins, and other sculpture, to each fountain. All these figures are to be cast in metal, and a good deal of the work is already far advanced. Even one such fountain would be considered a splendid undertaking in this country, and quite sufficient of itself without any accessories; what then will be thought, when we add, there will likewise be twenty rostral columns nine metres high, and forty candelabra? All these columns and candelabra will be cast in metal, which is to be partly bronzed and partly gilt, the bronze colour serving as ground to the gilding on the ornamental parts; and the columns as well as the candelabra will be lighted at night with gas, issuing from the projecting prows on their shafts. The effect, therefore, will be remarkably gay, not only on account of the brilliant display of light, but of the mode in which it will be applied, and the objects shown by it. In fact, the whole place will exhibit a complete illumination every night; yet, as if this would not be sufficient, the splendour will be increased on particular occasions and rejoicings, as the ball on the summit of each rostral column will have eight gas-burners, which will be lit at such times, so that the increase will be equivalent to that of one hundred and sixty additional gas lamps.

The model alone for the columns is said to have cost 27,000 francs, whence it may be supposed that the design is exceedingly rich. The weight of each is 4,200 kilogrammes, and that of each candelabrum 995; of these latter, there will be four around the pedestal of the Obelisk, and eight around each of the fountains. The improvements on this spot will not be confined to the above-described embellishments, for the chaussées or walks, intersecting the *Place*, will have trottoirs of granite; and the ground enclosed by the fossés, will be laid out in grass-plats, parterres, and low ornamental shrubberies, so as not to screen any part of the general plan.

We are of opinion, that something of a similar plan would be very suitable for Trafalgar Square; and were we permitted to offer our advice, we should recommend, that instead of following the general descent of the ground, the enclosed part should be a perfect level or esplanade, so as to form a terrace elevated several feet above the pavement at Charing Cross. The balustrade of this terrace might be continued along the other sides of the enclosure, and the whole would thus possess a different and more architectural character than the gardens of our squares. A rostral column in the centre would not only be appropriate, as emblematic of the victory at Trafalgar and other naval achievements, but be a novel and picturesque object in itself, such form being infinitely preferable for an ornamental monumental shaft or pillar than a mere column, looking as if it were a solitary member detached from some gigantic edifice, without having undergone any change to adapt it at all for becoming an independent and integral structure.

Madras Breakwater.—We understand that Government have received a despatch from the Court of Directors on the subject of the Breakwater, and that the Court have viewed the matter in a liberal way, expressing their willingness to take upon themselves the construction of a Breakwater, provided its feasibility can be made clear to them, and making the cost a matter of no consideration.—*Conservative*, Sept. 1.

CURTIS'S SAFETY IMPROVEMENTS FOR LOCOMOTIVES.

Fig. 1.

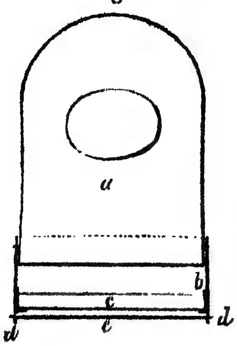


Fig. 2.

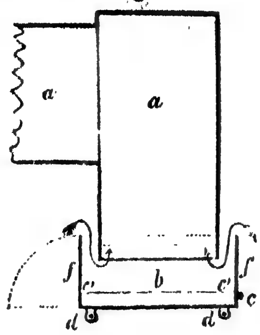

Ash-box consists of a movable tray or pan, which slides longitudinally either forwards or backwards, as may be required for discharging the fire. Two sides, with ledges for the tray to slide upon, are fixed to the sides of the fire-box, and united by tie-bolts at their extremities; two flaps, or doors, are provided at each end; so that which ever way the engine may travel, one may be open to catch the wind, and the other closed, to prevent dust escaping, or they may be both closed. The sides of the flaps rise higher than the bottom of the fire-box, so that the escape of cinders is impossible. The tray has all the four sides raised about two inches high, so that any escape of water from the fire-box is received into it, the steam from which very much assists the fire. The adaptation of this contrivance, and also the spark arrester, is very much called for, as I perceive, by the public papers, a farm has been burnt down, on the line of the London and Birmingham Railway, from sparks of fire from an engine.

Reference to plate, fig. 1 *and* 2.

a, is the fire-box and boiler; *b*, the sides of ash-box; *c*, tray; *d*, extremities of sides, through which the tie-bolts *e* pass; *f*, the flaps which have hinges at *c' c'*. The direction of the draught is shown by the curved arrows.

Apparatus, to counteract the effect of the frost upon the axles of locomotives (fig. 3), consists simply in suspending a trough below the axle, supplied with coke or charcoal; this is formed with plate iron, of the figure shown in the drawing. The fuel may be twelve or fourteen inches from the axle. A grate, formed of a piece of sheet iron, perforated with holes, passes the entire length between the axles, and the whole apparatus is suspended as close to the wheels as possible. The outside bottom, which forms the ash-pan, may be two or three inches from the grate, with raised ledges, to prevent the ashes falling out. A bushel of coke will last about three hours, for perhaps eighty miles. If found necessary, the same apparatus may be attached to the tender axles, as is evident.

Reference to the plate.

a, wheel; *b*, axle; *c*, suspended trough, with fuel; *d*, ash-pan, or lower bottom; *e*, a jointed rod connected with part of the frame or boiler, by which the apparatus is kept steady.

Fig. 3.

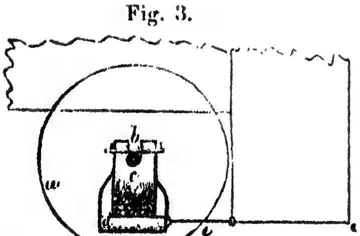

Fig. 4.

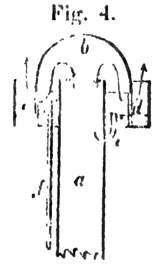


Spark arrester (fig. 4).—This contrivance consists of a dome placed over the top of the chimney, supported upon bolts, fixed in the bottom of a receiver, or water-vessel, by which means the sparks and dust from the fire are thrown down into the receiver, and there extinguished. This will be clearly perceived by reference to the plate, where *a* is the chimney; *b*, the dome; *c*, the receiver; *d*, the holding-bolts, or pillars; *e*, the escape-pipe, for the excess of water, the end turned up within the chimney; *f*, the feed-pipe, from the force-pump, by which a constant supply is kept up within the receiver: this pipe is connected with the pump behind the last valve; thus cold water is used, and there is no abstraction of heat from the boiler. The direction of the steam is shown by the curved arrows. This apparatus was at work for some time upon the Greenwich Railway, and answered perfectly; it does not impede the action of the engine in the least. I could never force a spark from it when the receiver contained water, as Messrs. G. Rennie and other gentlemen have witnessed, upon one occasion, when they went down the line upon the engine for the purpose of witnessing the experiment; not only are the sparks arrested, but the dust also, so that that very great annoyance is entirely removed. If it should be found necessary, a flap, or cover, may be placed upon the top of the dome, which may be opened when the steam is getting up, and closed when the engine is at work. It is scarcely necessary to observe, that the area between the dome and chimney, and between the dome and receiver, must always exceed the area of the chimney. W. J. CURTIS.

RAILWAY CHAIR.

Sir,—I observe in your last Number, a letter from Mr. Scott of Manchester, calling in question my right to be considered the author of the railway chair and mode of fastening, published in No. 4 of your Journal. He says, a chair, "with a place for the key rounded in the middle, has been used nearly two years, for the strong rails which have *lately* been laid down to replace old ones, in the Liverpool and Manchester Railway." This is very probably the case, but these chairs cannot be rounded in the way I propose; because, if so, and the rails are fastened without the wedges, a very absurd mode is adopted indeed. I recommend Mr. Scott to read the description of my chair again, and then he will find that the rounding the place for the wedge is useless, without the wedges on each side to spread out the timber, so that the contraction and expansion of the rail, and the traffic over it, may not affect the fastening. It is clear, again, that there can be no similarity in our methods, inasmuch, as his proposal to key his wedge was not, and has not, been adopted. as to priority of thought, I proposed to fasten all the chairs on the Greenwich Railway by this method fifteen months ago, and my method was published in the *Times* newspaper more than six months ago. The idea, that I could have obtained the secret from Mr. Scott, removed more than 200 miles from him, whom I never have seen, nor perhaps ever shall see! I have never been to Manchester, and only saw the Liverpool end of the Liverpool and Manchester Railway for about half an hour, upon one occasion. However, the fact for the public to know is, who published the matter first? he is *de facto* the inventor in all cases. A valuable secret is of no value to those who do not know it; I therefore advise Mr. Scott, if he has any other inventions, to lose no time in publishing them, lest he should be forestalled a second time, and if worth the attention of your Journal, I have no doubt you will be happy to afford him every facility for that purpose. Yours, &c.

1, Stafford Street, Bond Street. W. J. Curtis.

CONCRETE AND ARTIFICIAL COMPOSITION FOR BUILDING PURPOSES.

Sir,—I am not engaged in any trade or profession, but I reside on my own lands, in a district of much picturesque beauty, and abounding with chalk, flints, gravel, and sand, but entirely without building stone; and I have for some time endeavoured to ascertain the best materials and method for making a concrete or artificial stone of good appearance and durability, capable of resisting pressure and the weather, especially severe frosts, which so powerfully affects those of which the chief ingredients are lime or clay, whether in natural or artificial combination; but although I purchase most of the books* (of which I hear) treating on such subjects, yet the result of my inquiries hitherto has been by no means satisfactory.

Amongst other compositions recently brought into notice, are—

1. The French asphaltic mastic, which appears to be composed of tar and lime naturally combined, but too dear for extensive use here.

2. Cassell's patent lava, which seems to be tar without lime, and, perhaps, for want of that combination, to have not answered on the Vauxhall road, near the bridge, so well as had been expected.

3. Ranger's artificial stone, which is little more than a common concrete, mixed with a rather more than usual care, moulded and set with hot water.

I am rather disposed to attribute the superiority of the asphaltic mastic over Cassell's and Ranger's compositions to the former combining tar and lime naturally, which neither of the others do. I am the more inclined to this supposition, on account of the merit ascribed to a cement for which, in 1805, a Mr. Wilson obtained a prize from the Society for the Encouragement of Arts, and which consisted of boiled tar, with a little kitchen grease, used to mix slacked lime two parts, and finely powdered glass one part; and when made of the consistence of thin plaster, used to cover damp walls, or to join broken marble, &c. &c.; probably the grease was only (if of any use) to aid in repelling damp; and as to the glass, considering the nature of the materials of which it is composed, probably sharp sand would answer the same purpose, and then it might be made at a price and in a quantity suited for general and extensive use.

I enter into these details, and trouble you with this letter, in consequence of the notice taken in your January number of the asphaltic mastic, and in the hope that you may consider the subject of concretes and artificial building worthy of particular notice in your valuable Journal, to which, from its first number, I have been a subscriber and

A CONSTANT READER.

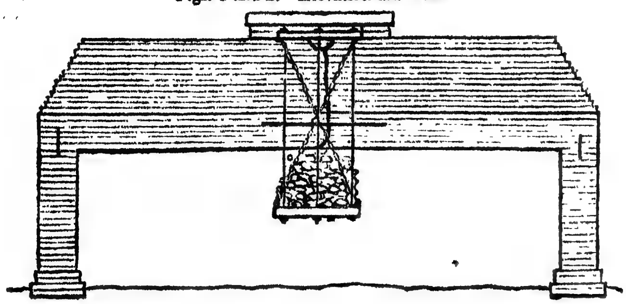
[We shall be happy to receive communications on concrete and other compositions suitable for building purposes.—Editor.]

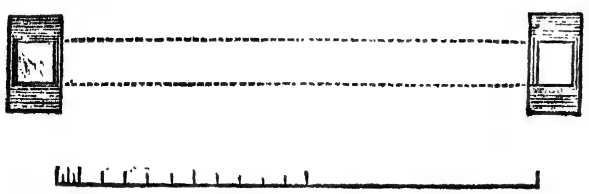
* A list of the books worthy of notice on such subjects would be useful, if inserted in your Journal.

EXPERIMENTAL BRICK BEAM.

ERECTED IN FRONT OF MESSRS. FRANCIS AND SONS ROMAN CEMENT MANUFACTORY, NINE ELMS, NEAR VAUXHALL BRIDGE.

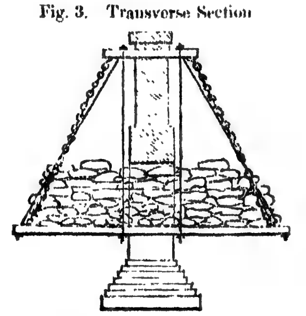
Figs. 1 and 2. Elevation and Plan.





Scale of Feet.

Fig. 3. Transverse Section



The above elevation, plan, and section, represents a beam or brestsummer, erected about two years since, by Messrs. Francis and Sons, under the direction of M. J. Brunel, Esq., to show the comparative strength of brick and cement, combined with hoop-iron. It was constructed of picked grey stocks, set with the best Roman cement, mixed with an equal proportion of sharp clean Thames sand; and in each of the lower courses of the beam, was embedded in the cement some iron hooping $1\frac{1}{4}$ wide by $\frac{1}{16}$ of an inch thick, laid horizontally, in all seventeen pieces.

The following are the dimensions: two piers, with three courses of footings 3 by $3\frac{1}{2}$ bricks, three courses $2\frac{1}{2}$ by 3 bricks, upon which stand two piers 5 feet high, 1 foot 7 inches or 2 bricks wide in the front, by 2 feet or $2\frac{1}{2}$ bricks thick; upon the top of the two piers was erected the beam, 21 feet 4 inches long in the clear, or 24 feet 6 inches out and out, 18 inches high, and 24 inches thick, upon which was erected a brick wall, 3 feet 3 inches high, by two bricks thick; a horizontal cement fillet was attached to the brickwork over the centre, and two similar vertical fillets at the ends; these fillets are marked with a dark line on the drawing, and were introduced to show when there was any settlement or deflection in the beam; over the centre a scale was suspended, in which was placed a quantity of scrap iron, weighing 10 tons 14 cwt. 1 qr. 4 lbs.; the greater part had remained suspended for nearly two years.

The ground upon which the beam had been erected being required for the terminus of the Southampton Railway, it was necessary to remove the same. Previously, Messrs. Francis and Sons were desirous of trying what additional weight would break the beam asunder; accordingly, a number of professional and scientific gentlemen were invited to witness the experiment, which took place on Wednesday, February 14, 1838, when the following gentlemen were present:—Messrs. Brunel, Donkin, F. Bramah, Sydney Smirke, Hardwick, jun., Spottiswoode, Taylor, Barnard, Brathwaite, Erickson, Lindley, Lowe, Herapath, Fox, Macneill, Riddle, Hawkins, Laxton, Higgins, Field, Rogers, Barnes, Pocock, Cottam, Manby, Lund, Mills, Garling, Webster, Willshire, Grimsdale, Hicks, Bellamy, Ward, Solly, Varley, Taylor, &c., &c.

About half-past twelve o'clock the experiment commenced. A line was first stretched across the underside of the beam, at a distance of three-quarters of an inch below the beam at each end, and only half an inch in the centre, indicating a deflection of a quarter of an inch, which probably was owing to an irregularity in the surface of the materials, as there was not the slightest appearance of any crack or fracture in any of the joints, or in the cement fillets on the face of the beam. A large quantity of railway bars were provided, and gradually laid on the scale, until the beam suddenly broke (about half-past two o'clock) with an *increased* weight of 11 tons 13 cwt. 3 qrs. 2lbs. Up to the time of breaking, there was no sensible deflection beyond what was perceived at the commencement of the experiment, nor any perceptible fractures or cracks in any part of the beam, or in the cement fillets. The beam broke as near the centre as possible, and the fracture run up to within a few inches of the top of the beam, when it divided, and forced out a wedged shape piece of brickwork, as shown in the drawing by a dark irregular line. It was a *clean* fracture across the brickwork; scarcely any of the cement joints were broken, which proved the goodness and efficacy of the cement; the piers remained firm until the moment of breaking, when the beam parted from them, at the horizontal joint on the top of the piers, and forced them both outwards. Most of the iron-hoops broke short off, one piece was drawn out about six inches, and another about three inches; they all appeared to adhere very firmly to the cement.

In addition to the foregoing remarks, collected on the spot at the time of the experiment, we have made the following calculations, to ascertain the comparative strength of the experimental beam of brick and cement with timber:—

	Tons.	cwt.	qrs.	lbs.
Weight suspended previously to the day of experiment	10	14	1	4
Weight added on the day of the experiment . .	11	13	3	2
Total breaking weight	22	8	0	6
Weight of the brick beam and brickwork over, calculating the quantity above, and *in the clear* of the piers, and allowing a rod of brickwork to weigh 13 tons .	8	2	0	0
Total breaking weight, 68,326lb. =	30	10	0	6

If we consider the size of the beam to be 21 feet 4 inches in length, being the distance between the piers, the breadth of the beam 2 feet, and the height up to the top of the set off 1 *foot* 6 inches, we shall have for the length (l) 296 inches; breadth (a) 24 inches; depth (d) 18 inches.

Breaking weight, (w) 68,326 pounds.

Now, if we take Barlow's formula for the strength of a beam supported at both ends, and loaded in the middle (vide Journal, No. 2, page 20), viz. $\frac{l\,w}{4\,a\,d^2} = S$, and substitute for this formula the dimensions and breaking weight of the beam, we shall have $\frac{292 \times 68{,}326}{4 \times 24 \times 18^2} = 641$ as the strength of the beam.

If, in consequence of the brick wall above the set-off, or above the part we consider as the beam, the weight is *equally distributed* over the beam, then it ought to carry double the weight of a beam loaded in the centre; in that case, we must divide 641 by 2, which will give the strength of the beam as only 320·5.

If we compare these results with Barlow's table of the comparative strength of timber (vide Journal, No. 2, page 21), we shall find that the experimental beam, according to the first calculation, is not much more than half the strength of oak or fir, and, according to the second calculation, is not much more than a fourth.

Then, again, we have heard it argued, that the whole height of the brickwork above the opening ought to be considered as the depth of the beam, with which we cannot agree; in that case the comparative strength will be very low indeed, as we must then consider the beam 21 feet 4 inches, or 292 inches in length, breadth 18 inches (the thickness of the upper part of the brickwork), depth the whole height 4 feet 9 inches, or 57 inches, plus the additional size of the lower part, 6 inches in width by 18 inches in depth; the formula will then stand thus:

$$\frac{292 \times 68{,}326}{4 \times 18 \times 57^2 + 6 \times 18^2} = S \text{ or } 82{\cdot}5:$$

thus it will be perceived the strength is comparatively nothing.

The next and most important consideration will be of what advantage are the pieces of hoop-iron which are introduced in the joints of the beam, and whether they act as a tie-bar.

We have fifteen pieces of hoop-iron, $1\frac{1}{4}$ by $\frac{1}{16}$, their aggregate equal to a bar of wrought iron $1\frac{1}{4}$ by $\frac{15}{16}$, or a bar $1\frac{1}{8}$ inch square; if they act as a tie in a state of tension, their strength will be equal to the cohesion of the bar.

According to the experiments made on the cohesive strength of an inch square bar of wrought iron, we have the mean result of

11	experiments	by Captain Brown	= 25 tons.
9	do.	by Mr. Telford	= $29\frac{1}{4}$
10	do.	by Mr. M. J. Brunel	= $30\frac{8}{10}$
4	do.	by Mr. Barlow	= $25\frac{1}{4}$
10	do.	by Mr. Telford on *wire* . . .	= $38\frac{4}{10}$

and, according to Mr. Barlow, we may consider the elastic power of good medium iron as equal to about 10 tons, and that the force varies from 10 to 8 tons in indifferent and bad iron.

If we take Mr. Barlow's result as the cohesive strength of a bar an inch square at $25\frac{1}{4}$ tons, it will give, as the collective strength of the fifteen hoops, very nearly 30 tons. If we refer to the total breaking weight of the beam, it will be found to very nearly coincide with the above calculation.

Now comes the argument, to decide in what manner the breaking weight acted on the iron hoops, and whether the iron could have been extended according to its elastic power, or whether, by the adhesion of the cement to the iron and brick, the bars were prevented being extended or stretched, and could only break when the force exceeded the whole cohesive power of the iron.

In the first place, if the iron had stretched, would there not have been a

fracture and deflection in the beam long before the breaking weight was applied? in fact, whether a deflection and fracture would not have been observed before the increased weight was added? as the weight which had previously been suspended, together with the weight of the beam itself, were considerably greater than the elastic power of the hoops.

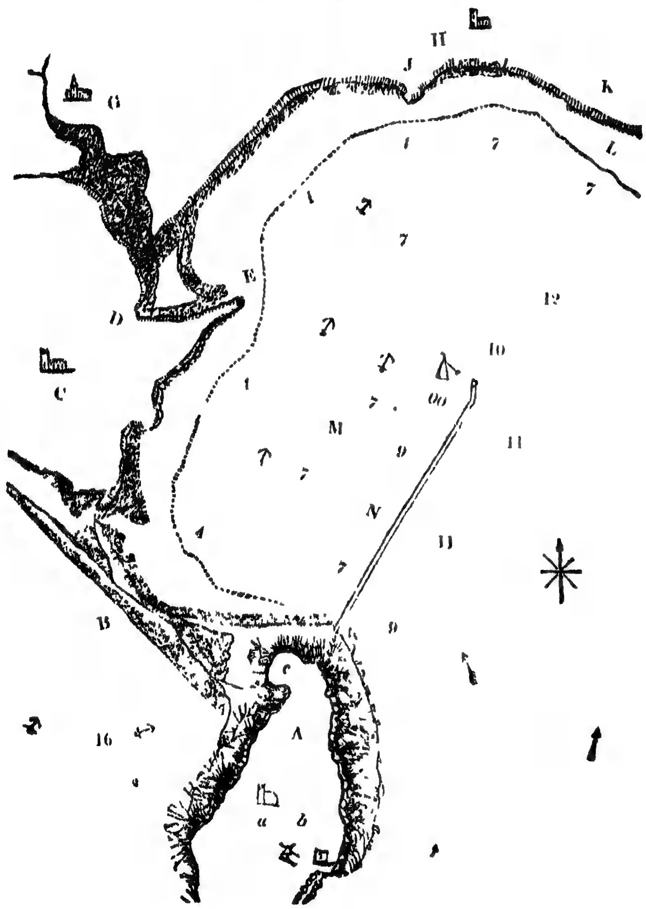
In the second place, if the hoop-iron did not extend before the beam broke, then it would require a force equal to the whole collective cohesive strength of the hoop-iron to break the beam.

The result of the experiment before us appears to bear out this view of the argument. In such case the bricks and cement are only necessary to prevent the extension of the iron, which is borne out by the result of Colonel Pasley's experiments (vide Journal, No. 2, page 30), viz., a beam without hoop iron was broken with a weight of 498 pounds, and a similar beam, with iron bond, was found capable of supporting 4,723 pounds; therefore $4,723 - 498 = 4,225$ the amount of strength gained by the use of iron bond.

[We shall be obliged for any remarks and calculations connected with the above subject from any of our scientific correspondents.—EDITOR.]

HARBOURS OF REFUGE.

PORTLAND HARBOUR.



EXPLANATION OF ENGRAVING.

A Isle of Portland. a New Church b Windmill c Stone Quarry. B Chesil Beach C Church Wyke Regis D Weymouth E North Point F The dotted line, showing the boundary of low-water mark G Radipole Church. H Preston Church. J Radcliffe Point K Mill Cove L Rigestead Ledge. M *Portland Harbour.* N The Breakwater. O Floating Light.

The *figures* indicate the sounding, and the *anchors* the ship's moorings.

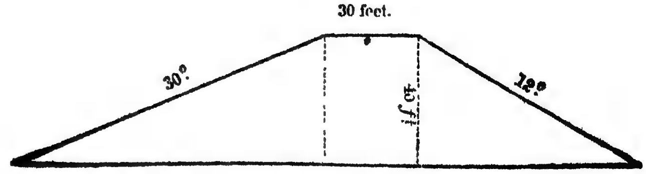
WE observe, that on the 21st of November last, Mr. George Frederick Young, Member of Parliament for Tynemouth, the intelligent and persevering advocate of the shipping interest, has given notice, that he intends, on the 1st of March, "to call the attention of the House to the expediency of making legislative provision for the construction and maintenance of Harbours of Refuge, on the most exposed and dangerous parts of the coasts of the United Kingdom"—a subject of vast importance to a maritime state, whose rank, influence, and importance amongst the great family of nations, depends so much on its marine, a force that cannot be either created or sustained, without an extensive and *prosperous* commerce. Sensible of this truth, great encouragement was heretofore given by former governments to the ship-owners of this country, under a system of laws generally denominated the Navigation Laws. These laws are either repealed or so altered, that the commerce of this country has now, under many disadvantages, arising from our erroneous system of revenue, to compete with other nations more fortunate in that respect than ourselves; it becomes, therefore, a subject of vast importance to the country generally, that its maritime strength should not be undermined and weakened, whilst that of other nations is increasing. To maintain its relative station, the maritime strength of this country must progress in the ratio of its superiority, and nothing will contribute more essentially to its success, than harbours of refuge, in the exposed and dangerous parts of the coasts of the British Isles, which vessels may enter, and from which vessels may sail at all times, free of expense.

Important, however, as harbours of refuge will unquestionably prove to the United Kingdom, yet the value of any *one* of such undertakings will *in general* depend on the proportion which the cost will bear to its value; though, in some particular instances, the value so far exceeds the power of calculation, as in the cases of Cherbourg and Plymouth, the cost is as nothing, when compared with the utility.

We have been led into these reflections by the perusal of two papers, published by Alexander Lamb, Esq.; the first entitled, "Suggestions for converting Portland Roads into a Harbour—1826;" and the other entitled, "Reasons for converting Portland Roads into a Harbour, showing that it will facilitate and lessen both the risk and outlay of commerce, benefit agriculture, reduce the expenditure of the country, and add to its security—1836."

The perusal of these papers led us likewise to make some inquiries respecting the two celebrated works abovementioned, the dike of Cherbourg, and the breakwater of Plymouth. The dike of Cherbourg was formed, in the first instance, of hollow cones of timber, filled in with loose stones, and upon the destruction of these cones, converted into its present form; the stones being left to the action of the sea, it is found that towards the roadstead or landward, the stones have maintained the angle of about forty-five degrees, but that, towards the sea, the angle has been reduced to one vertical for ten or eleven horizontal, which is probably a safe angle for a sea-slope, formed of small stones, there being few situations more exposed than the dike at Cherbourg; yet still the angle seaward must, in a great measure, depend on the weight of the stones, the rise of the tide, the velocity of the waves, and the angle at which the sea will strike it, under the influence of violent gales of wind. The Plymouth Breakwater, formed with stones of the average weight of three tons, has a sea-slope of about one in five, and towards the roadstead of the slope is about one to two. The casing of this breakwater, towards the sea, has been made with the heaviest stones, and the result of this judicious arrangement has been, that the tremendous swell setting into the harbour during, and after a high wind, has scarcely removed a single stone since its erection, excepting from the part above high water, which in the hurricane of 19th January, 1817, was destroyed to the extent of two hundred yards in length, and thirty yards in width.

If a breakwater be required merely to cover a roadstead or harbour, there is no necessity to raise it higher than one foot below low-water of spring tides. At Cherbourg the upper surface of the breakwater is very irregular, varying from three to fifteen feet below low-water mark; but the average may be taken at four feet below low-water, spring tides; and here it has been found that the roadstead is sufficiently protected to shelter a fleet of forty or fifty sail of the line during the heaviest gales, although the average rise of the tide is about twenty feet. Taking the proportions, such as those given in the Cherbourg and Plymouth breakwaters, the safe dimensions, as a general rule in practice, will be three-fourths the depth, for the width of the parallelogram, an angle of thirty degrees or slope of 1 in 2 towards the roadstead, and of twelve degrees or 1 in 7 towards the sea; thus the depth being forty feet, the breadth of the parallelogram will be thirty feet, as shown in the annexed diagram.



The action of the wind upon the sea is not instantly to break it into waves, a squall has the effect of merely blowing off the surface in spray, without permanently disturbing the quiescence of the mass. Water, like all other ponderous bodies, resists by its gravity the action of any force to disturb its equilibrium, and it is only after a violent wind of some hours' continuance that the sea rises; and those who have crossed the ocean, know well enough that the most dis-

agreeable waves are always produced after the gale is over, and the sea is subsiding by its gravity into quiescence.

The lower, or underside of a wave, has a less velocity than the upper; this is occasioned by the friction produced upon the under surface by the dead water or the shore, and the surface or upper part of the wave being acted upon alone by the impelling force of the wind, so that a wave always runs over itself; when the upper stratum reaches the extreme point, it falls over in foam, as over a precipice, the slower moving under stratum still keeps advancing, the wind gives a fresh impulse to the newly-exposed surface, and the action is again repeated: thus there is here a compound action; but when the wind has ceased, the active wave ceases, and then the heavy roll takes place, which a ship and the shore feel as much or more than the waves during the storm; and for this reason, after the wind has abated, the waves act upon the principle of a pendulum, with a certain degree of regularity, and uniting, the water rises against a wall or breakwater through a greater breadth: thus the wall or breakwater is exposed to a much heavier pressure than if the water were to spend its force against it in narrower waves, and the less exposed portion of the wall assists by its gravity and cohesion to sustain the shock upon the other part.

The wind is always intermitting in its action; were it not so, the water would rise to a height, and receive an impulse so immense, that nothing of human construction could withstand it.

Although it is a common expression to say that the sea ran mountains high, yet the agitated water never exceeds twenty feet in depth; and if we take its extreme horizontal velocity at ten miles per hour, or fourteen feet in a second, the pressure upon every foot of a horizontal surface will be near four tons—a prodigious force when spread over a large surface, but which is reduced almost to nothing by the sloping side of the breakwater, which reduces the mean depth of the water, and the velocity, at every period of the wave's progress, leaving only one foot of active water to flow over the breakwater, the effect of which will be destroyed as it rolls onward by the resistance of the dead water within the breakwater; thus the shipping in the roadstead floating the greater part of their depth in calm or dead water, remain in perfect security, and but for the action of the wind upon their hulls and rigging, would remain almost immovable even without an anchor.

The tides from the Western Ocean set into the English Channel in the direction of a line drawn from the Lizard Point, on the coast of Cornwall, to Cape La Hague, on the coast of France, nearly north-west by west; the consequence is, that the tides rise higher against the coast of France, and the isles of Jersey, Guernsey, and Alderney, than at any other point of the Channel; the average rise of spring-tide at Jersey being forty-five feet, Guernsey and Alderney thirty-five feet, Cape La Hague and Cherbourg twenty-one feet, whilst at Weymouth and in Portland Roads, on the shore directly opposite, the tide rises only from six to eight feet; thus the coast of France, from Cape Finisterre to Cape La Hague, is formed into a breastwork, upon which the force of the Atlantic is spent, throwing the water round in an eddy upon the British shore; so that Cape La Hague and Cherbourg check the tides and shelter Portland, and the shingle which is not left upon the French coasts is thrown behind the Bill of Portland, and upon the coasts of Devon and Cornwall, converting such of the harbours on those coasts that are not protected by some projecting head-land into *bar* harbours.

The idea of converting Portland Roads into a harbour of refuge for ships passing up and down the English Channel, is due to Alexander Lamb, Esq., who in the year 1812 arranged the plan in his own mind, and in the following year employed Mr. Dessiou, the hydrographer, to survey Portland Bay, and furnish a report upon which himself and friends might act. From the period above-mentioned to the present time, Mr. Lamb has employed a great deal of time and money in laying his suggestions before the Government and Parliament. He has collected such a mass of facts and evidence bearing upon the point, that in a desire to lay before the public the merits of this important work, we cannot do better than quote his own pamphlet, published last year.

By the addition of a stone reef or breakwater, raised one foot above low-water mark at ordinary spring-tides, to the natural boundaries of Portland Roads, and running in a north-eastern direction from the north eastern part of the island, a convenient and capacious harbour would be formed, at the comparatively small expense of £400,000, affording great extent of shelter and means of accommodation to every description of shipping, from the lowest to the highest class, and combining the singular facility of allowing ships to put to sea whenever the weather might permit, whether bound up or down Channel, from whatever point of the compass the wind might blow.

The harbour would accommodate many ships of the line, and numerous smaller vessels, in an anchorage of from six to nine fathoms, in ground of peculiar excellence; great part of the bay being of tough, blue clay, with a slight surface of sand and shells, entirely free from rock and every other impediment to safe anchorage; and as there is here little, if any tide, vessels waiting for a wind might weigh and put to sea, night or day, the moment of a favourable change.

The French and English coasts first approximate to (ships passing up Channel) at the points marked by the caskets on the south, and Portland on the north, between which the Channel narrows to forty-six miles; and the dread of the English coast on the part of the mariner approaching from the westward, through the want of an English harbour, to which he might run in any of the various hazards of navigation, is the cause of frequent shipwreck on the opposite shores.

In the event of the conversion of Portland from an exposed roadstead to a harbour, the mariner would not only avoid this danger, but would approach the English coast with the confidence inspired by the certainty of easy access to a good port, to which he would be conducted by the fine lights exhibited at the points of the Channel abovementioned; at present (however clearly the position of a ship may be ascertained by these lights), they indicate no harbour or place of shelter; the Needles' passage, whatever may be the attention directed to its improvement, must continue to be difficult and dangerous, and is to be attempted during the night, even by the most experinced, in cases of emergency only. By her Majesty's ships of the largest class, this passage will not be used unless urged by the most pressing circumstances.

The advantages to the commercial interest of a harbour at Portland, in regard to ships bound down Channel, would be very great. If viewed in comparison with the Downs or Portsmouth, the saving and facility in every duty and service connected with a final dispatch of a ship for sea would be considerable, the communication with London easy, and an asylum would here be afforded from the storms so frequently fatal to ships upon quitting the Downs and ports to the eastward, as well as to ships bound up Channel, more effectually than in any other port on the south western part of the coast. In regard to ships touching for orders, the superiority of a harbour at Portland over Cowes is manifest.

The great loss and inconvenience which the commercial interests of the country suffer through want of such a harbour, is generally admitted.

Great expectations are formed of the supposed facilities railway communication will give to commerce and manufactures generally; and should those facilities prove equal to the anticipation of the promoters of them, Portland Roads, if converted into a harbour, must necessarily become one of the great points of concentration, situate as it is in the very centre of the English Channel, into which it is so prominently advanced, as to promote both the departure and arrival of vessels in a degree greatly surpassing any other port in the Channel; and this concentration will necessarily require a constantly increasing demand for the produce of the soil.

Beneficial as it has been shown a harbour at Portland would be to the commerce of the English Channel, and as it must be to the agriculture of the adjacent district, yet these, though important, are but partial interests;—it remains to be shown of what vast importance a habour at Portland would be as a national work.

If the present state of the great national work of France at Cherbourg, the selection of its situation by Vauban, the confirmation of his judgment by Buonaparte, the importance that was at first and has ever since its suggestion by Vauban been attached to it by the French nation, are taken into consideration, they deserve deep and serious reflection.

The construction of a harbour at Cherbourg was worthy of the great man who first designed it; and the completion of it in its present form will be a lasting monument to the memory of the extraordinary character who planned, and in part executed, the inner basins, which are now capable of containing upwards of fifty sail of the line.

Cherbourg will be, if not prevented, what Vauban intended it should be in a maritime war with this country,—a point of great annoyance; and any attempt to blockade a considerable fleet in Cherbourg during the winter months must be attended with great difficulty, and no inconsiderable share of danger, beside a certain and enormous expense in wear and tear.

In 1787, Lord Rodney, in a letter addressed to Governor Thicknesse, wrote—"If Cherbourg is once completed, then the British Channel is no more,—it will then be the French Channel;" and Cherbourg is now finished.

Should such circumstances arise as to render probable a war between any or all of the Northern States of Europe and this country, with France as our ally, a harbour at Portland might operate powerfully to prevent actual hostilities, or, at all events, to shorten their continuance, and very sensibly diminish expense. The distance between Portland Roads and Cherbourg is about sixty miles, and with a moderate fleet stationed at each, neither of them exposed to any wear and tear, and a few frigates and steam-vessels to look out, it would be easy, in a great degree, to close the English Channel against the fleets and commerce of any hostile power; a measure that would not fail to lessen the expense of a maritime war upon our own coasts, and greatly increase the security of our commerce, whilst that of the enemy would be impeded or exposed to a circuitous and perilous navigation—circumstances that would necessarily tend to shorten, if not prevent hostilities.

One circumstance remains for observation, which is of more importance than all the others combined, that is, the effect of a harbour at Portland in preserving the lives of our seamen, numbers of whom perish yearly in the English Channel for want of a harbour there. The catastrophes which occasioned the loss of so many valuable lives in the Halswell and Abergavenny East Indiamen, and in the fleet under the command of Admiral Christian, are matters of history; but lives lost in ordinary merchant vessels, without reckoning those lost in foreign vessels, are scarcely noticed. These are, however, considerable, and it is to be hoped, and indeed is confidently believed, that few people exist in her Majesty's dominions who would not

gladly contribute their mite towards the formation of this harbour, if they conceived it would be the means of preserving one human being from an untimely death, especially when it is explained to them that the work may be accomplished for the comparatively small sum of £400,000, which a subscription of fourpence by each inhabitant of the United Kingdom would produce, but which may with more facility be raised on the credit of a duty of one farthing in the pound on the value of the goods and merchandise which pass Portland in merchant vessels.

It is proposed to form the breakwater with the cap stone overlaying the marketable stone of the neighbouring quarries, which is required to be removed to obtain the latter; thus stone, ready prepared, is upon the very site most favourable for its delivery along the line of the works; the quarries are at the top of the hill, about three hundred feet above the sea, so that, by suitable apparatus, it will be brought down and deposited along the line of the breakwater by its own gravity, at all periods of the tide, and in all seasons; thus facilities for the rapid and economical construction of the works are provided, which can be found nowhere else throughout the whole coast. It is proposed to carry out the breakwater two miles and a half in a north-easterly direction, from a point nearly in a line with Fern Hill, on Portland, to another point in Ringstead Bay, on the opposite shore; thus covering an area of four square miles of roadstead, and leaving more than two miles, from the point of the breakwater to the opposite shore, for ships to work out or run into harbour.

The pamphlet which we have so largely quoted abounds in such forcible and convincing arguments in favour of the undertaking, that nothing remains for us to write in further recommendation of it; it is to be hoped, that when the subject is brought before Parliament, that it will be received and treated with the consideration due to its deep and surpassing importance, and that no further delay will take place in completing a work equally called for by sound national policy, the interests of commerce, and considerations of humanity.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL ACADEMY.

At the last election of members, which took place on Saturday, Feb. 10, there were the unusual number of four vacancies, occasioned by the deaths of Sir John Soane, Mr. Constable, Mr. Westall, and Mr. Wm. Daniel. In their places were chosen—Mr. Uwins, Mr. Wyon, Mr. F. Lee, and Mr. Deering, four gentlemen whose election was as honourable to the Royal Academy as to the individuals elected. With the tribute paid to Mr. Wyon, we confess we were particularly gratified, as it was a triumphant answer to the unpatriotic and unjust efforts which have been made to place the merits of this distinguished artist below those of a foreigner, who holds an appointment also in the Royal Mint. Such unfeeling efforts have been nobly disregarded by the best judges in the land, the members of the Royal Academy; who, in choosing Mr. Wyon to be their fellow, have shown that they will not, at the bidding of the Nebuchadnezzars of taste, fall down and worship the brazen image which has been set up.—*Literary Gazette.*

INSTITUTION OF CIVIL ENGINEERS.

THE ANNUAL REPORT.

The Report of the Council on the state of the Institution, and on the proceedings of the past year, contains an account of the origin, constitution, and nature of the Institution, which cannot fail to be read with great interest by all in any way connected with the profession.

It appears that the by-laws have been revised, and several important alterations introduced. Among these a most important one is the rendering the qualifications of the various classes more distinct and explicit, so as to give a more decided character of organization to the Institution, by the incorporation in one class of those who possessed the same qualifications, and by the creation of a new class, for the admission of those who, under the old laws, were included in a class requiring other qualifications. The following extracts from the Annual Report will serve to explain the nature of these changes, and to show the present state of the Institution, which is calculated to contribute so much to the advance of the science of Engineering in every department:—

"The useless and merely nominal distinction betwixt Members and Corresponding Members has been removed; their qualifications being identical, the existence of this nominal distinction and of two classes could not fail of being attended with disadvantages, and has been misunderstood as implying a distinction which was never contemplated.

"These two classes are, by a Special Resolution of the General Meeting of Members, to be incorporated in one class in alphabetical order.

"The qualifications also for admission into the class of Associates were very ill-defined; the whole rising generation of Engineers, or future Members, being included in this class, it was thereby rendered devoid of the distinct character which it ought to possess.

"The creation of a new class, under the term Graduates, will, it is expected, afford the means of that classification which was so much to be desired. In this class will be enrolled those who, either as pupils or assistants to Engineers, are qualifying themselves for the practice of the profession, and are attaining to that degree of experience and knowledge which, in the opinion of at least ten of the general body, with the concurrence of the Council, will entitle them to be enrolled in the class of Members.

"The class of Associates will, it is expected, in future consist of men of experience in pursuits connected with the practice and profession of the Civil Engineer. By the assistance and co-operation of this class, the boundary of knowledge in the infinite variety of subjects which come under the attention of the Engineer, may be extended, and thus that which the talents and resources of one could not attain may be readily attained by the co-operation of many engaged in similar pursuits.

"The existence of a class of Honorary Members, consisting of eminent Engineers of foreign countries, and of others illustrious for their attainments in science, and experience in matters connected with the profession of the Engineer, enables the Institution to connect itself with the names of those of every country who shed a lustre on the profession, or on science in general.

"Thus it is conceived that the Institution has been more adapted to the wants of the present generation, and as it was the wants of society which first called it into existence, so may it reasonably be expected that the continuance of those wants will keep it in a state of progressive improvement and adaptation. The nature of these wants, and the means by which they were in a great measure to be relieved, are, in the address of your Vice-President, Mr. Palmer, to the Meeting which called this Institution into existence, set forth in the following manner:—

"'It is a remarkable fact that, notwithstanding the extensive advancement of science and the general increase of means for an acquaintance with it, that while the principle of systematic education for most of the learned and scientific professions have been and still are actively encouraged, not even an attempt seems to have been made towards the formation of any special source of information or instruction for persons following or intending to follow the important profession of a Civil Engineer, in the practice of which the utmost skill of man is called forth, and which requires not only a knowledge of one leading branch of science, but many—not only of one leading art, but of an indefinite number. For the Engineer, being a mediator betwixt the Philosopher and the working Mechanic, must, like an interpreter betwixt two foreigners, understand the language of both. If, then, we consider for a moment the continued application necessary to familiarize us with any one branch of art or science, surely any argument to enforce a persuasion of the utility of an Institution to facilitate the qualification for a profession in which many branches of both art and science are necessary, must be superfluous.'* By such feelings were your Vice President and first Members† then actuated in forming the Institution; and that these wants, then so urgently felt, have been in some measure supplied, no one can doubt who looks to the continued progress and present state of the Institution. The attainment, in some measure, of the objects proposed, has kept the Institution in a state of progressive improvement up to the present time, and the continued co-operation of all classes cannot fail of producing similar good effects in time to come. For by the opportunities here afforded, the more experienced in the profession may extend their knowledge by communicating with others equally experienced; the rising generation of Engineers may communicate with each other, and receive instruction from the oracles of the profession, and acquire knowledge which conversation alone can give. Here, also, in the records of the Institution, all may become acquainted with the opinions and the practices of the past and the present, and possess opportunities of consulting works and documents to be found in no other place. And when to these advantages are added that of meeting with men of eminence in collateral pursuits, as Associates and Honorary Members, the Council do conceive that the spirit in which the Institution was projected has been well followed out, and its good effects in some measure realized; and that the experienced Engineer, no less than the Student in the profession, possesses opportunities for which, twenty years ago, he would have sought in vain.

"'Much has at times been said respecting the establishment of a School of Engineers, and many comparisons have been drawn betwixt the advantages possessed by this and other countries in this respect; but not for an instant to enter on the great question of the nature of a complete establishment under that name, it may with confidence be asserted, that this Institution is in itself a School of Engineers—a school, not in the sense of the term where knowledge is forced upon the unwilling student, but one where the attentive student possesses remarkable opportunities of self-improvement by study and mutual intercourse.

"'The attention of the Council has been directed to the publication of an Abstract of the papers read, and of the conversations which take place; and such an Abstract, under the title of Minutes of Proceedings, was published soon after the close of last session; and it is the wish of the Council that these should appear at regular and short intervals during the session, while the subjects discussed and alluded to are still fresh in the recollection. On the advantages of this plan it is almost unnecessary to insist, since it has been adopted and approved by many eminent Societies. The public is thus brought immediately into contact with the Institution; the labours and opinions of the author are made known and canvassed while the subject is yet warm with interest, and attention is continually kept alive to the state and progress of each department of knowledge. An authentic and public record also is thus opened, and the credit due to authors for priority of invention and discovery is secured as matter of history. Add to which, there are communications of transient interest, but which could not be deferred to the Publication of the Transactions. It is conceived that the Minutes of Proceedings will furnish a record of papers, remarks, and events, of partial or transient interest, which would be comparatively of little value, unless published at the time; and that the Transactions is the channel through which all more elaborate communications of universal and lasting interest are to be brought before the world.

"'The attention of the Council has also been directed to the publication of another volume of the Transactions; several communications have been selected, and the work is in so forward a state, that the Institution may confidently expect the publication of the second volume before the close of the present session.

"'The Council have also to congratulate the Institution on the completion of the Telford Prize Medals. This beautiful specimen of Mr. Wyon's skill, with the head of Telford on the obverse, and the Menai Bridge on the reverse, was completed last year, and at a public dinner of the Institution, on the 3d of last June, the following medals were presented:—

A Gold Medal to John Timperley, for his MS. account of the Hull Docks.

A Silver Medal to each of the following—

To John Macneill, Member, for his Canal Boat experiments.

* See Address by H. R. Palmer, Jan. 2, 1818; Minutes of Session, 1818.

† Messrs. William Mandsley, Henry R. Palmer, Joshua Field, James Jones, Charles Collinge, and James Ashwell.

To James M. Rendel, Member, for his account of the Lary Bridge.
To Michael A. Borthwick, Associate, for his account of Iron Piling.
To Benedetto Albano, Associate, for his account of the bridge at Turin.
To Peter Barlow, Jun., for his paper on Lock Gates.

"'The communications for which these were adjudged are recorded in the first volume of the Transactions of the Institution.

"'The Council have to regret the loss to the Institution by death of its Member, Arthur Woolf. This distinguished individual was born at Camborne, in Cornwall. He was a millwright, and in that capacity went to London, and was employed in Meux's Brewery. In 1801, he took out a patent for his Two Cylinder Engine, working high pressure steam in a small cylinder, and allowing it to expand in a large one. When he first commenced erecting engines in Cornwall, he induced the proprietors of the foundries to improve their machinery, that a better style of workmanship might be used in the manufacture of steam-engines: and he introduced an improved Hornblower's double beat valve. The work done at the Consolidated Mines, proves him to have been a person of great talents. In October, 1814, the average duty of the engines in Cornwall was 20½ millions; Woolf's engine at Wheal Abraham, however, performed 31 millions; and in December, 1815, 62 millions; and in May, 1816, 67 millions; while the average duty of all the engines reported in Cornwall was 23 millions. In 1820, Mr. Woolf erected engines at the Consolidated Mines having cylinders of 90 inches in diameter, and a stroke of 10 feet—the most powerful that had ever been constructed. In December, 1827, a trial took place with one of Woolf's 90 inch engines, and it performed a duty of 63½ millions—the average duty of 47 engines reported in this year was 32 millions. For some years before his death he received a pension of 100l. a year from the proprietors of the Consolidated Mines. His name is associated with the improvements in the drainage of the Cornish Mines; and whatever share posterity may assign to his individual genius in these improvements, his name is recorded in the page of history among those who have dedicated their talents and the opportunities of a long life to the advancement of practical science.

Abstract of Papers read at the Institution of Civil Engineers, January 9th, 1838; W. Cubitt, Esq., V.P., in the Chair.

On the Duty of the Cornish Engines, by Thomas Wickstead.

Mr. Wickstead having obtained permission to make a trial of an engine upon the Holmbush mines, near Callington, proceeded to ascertain, with great accuracy, the dimensions of the engines and the pumps, and the duty performed.

The diameter of the cylinder was 50 inches, and the whole height of the lifts 535 feet 6 inches, and the diameters of the tie and rose lift pumps were 11 inches, and of the bottom lift 10 inches.

He had 94lbs. (a Cornish bushel) of coals weighed, and took every precaution to ascertain exactly the work done by this quantity. Previous to the trial, the length of the pump-stroke, viz. 5 feet 1 inch, was measured, and the quantity of water delivered per stroke was found to be equal to 285·6lbs. The steam was cut off at one sixth of the stroke, and the temperature of the cylinder in the jacket fully kept up by a free communication with the steam in the boiler. In making the trial, the fire under the boiler was worked down as low as could be without stopping the engine—the pressure of the steam being 10lbs. on the square inch in the boiler. Taking the counter, and the time the engine was started, at the end of 2¼ hours the fire was lowering and the speed of the engine reducing, and it was necessary to have more fuel; the 94lbs. of coal having been consumed, the engine was then stopped, and the counter again taken; it had made 672 strokes, or nearly 5 strokes per minute; the weight of the water raised was 1,918,282lbs., so that the product of the weight and the height through which it was raised, expressing the performance of the engine, was 102,721,323lbs of water raised one foot high with 94lbs. of coal.

This result, however, although it shows the quantity of water raised, does not show the duty of the engine, as no allowance has been made for the unavoidable leakage of the pumps; the fairer method, therefore, of calculating the duty of the engine is from the product of the areas of the pumps, the length of the stroke, and the pressure due to the column of water equal to the height of the lifter; and the duty of the engine in question, calculated upon the above principle, is equal to 117,706,992 lbs. lifted one foot high with 94 lbs. of coal. The author observes, that the engine had not been overhauled, or anything done to it, to prepare for the trial, the particular engine upon which the trial was to be made not having been determined on until the previous day; also, that the boiler and flues had not been cleaned for eleven months. The object being to prove what could be done by an engine worked upon the expansive principle, Mr. Wickstead considered that a trial for two hours would prove the capability of the engine, although most probably the average duty of the engine for twelve months would not be so great as it was for the short time that it was under trial.

Having calculated the effect which could have been produced by the steam-power, provided the engine and pump gear had worked without friction, the difference of the result obtained, and the *duty* of the engine, shows the amount due to the friction, which in the present case was equal to 93,751,710 lbs. raised one foot high, or about 7·75 lbs. pressure per square inch.

It having been observed that the expansive principle would not answer for rotary or double engines, Mr. Wickstead was induced to make some observations upon a double engine, working the stamps for breaking the copper ores at the Turcroft mines. The steam was cut off in the down stroke at two-fifths, and in the up-stroke at one-third, the engine working with a very equal velocity, and upon an average consumption of coal of 30 bushels for the 24 hours. The engine was working a set of stamps—a pump—a crushing machine—and a tumking machine; and the result of the calculation was, that the duty done by the engine was 50,525,072 lbs. lifted one foot high with a bushel or 93 lbs. of coal.

Mr. Wickstead has given two tables: the first is a table, chronologically arranged, exhibiting the gradual improvements of the steam-engine in the course of 66 years; the second, the average duty performed by the engines in Cornwall in 1835 and 1836; and, on the authority of Mr. John Taylor, a comparison of the depths of the Cornish mines at different periods, the water raised, and the coals consumed, showing a saving upon the books of the mines proportionate to the improvements in the working of the engines, stated to have been made during those periods.

The average weight of the coal used in Cornwall is 93 lbs. per bushel, and that the 94 lbs. above mentioned was the Cornish bushel by weight and not by measure. The coals used in Cornwall are nearly all imported from South Wales, and chiefly from the ports of Swansea, Neath, and Llanelly, but are generally of second-rate quality, the better sort being selected for other purposes.

The advantage gained by having steam of a high temperature in the steam jackets of expansive engines is very great. The best engines in Cornwall have the steam jackets supplied from a pipe communicating directly with the boiler. About eight years since, the jacket of an 80-inch steam cylinder at Wheal Towan mine became leaky at the joints, and they were obliged to shut off the steam from the cylinder jacket for a month; that immediately upon so doing they were obliged to pack the piston afresh, as it would not work, which was attributed to the contraction of the cylinder, in consequence of there being less heat, there being no steam in the jacket; that the duty done by the engine this month was but 55 millions, whereas, when the steam was admitted into the jacket, both before and after this period, the duty done was 70 millions.

On Captain Huddart's Improvements in Rope Machinery; by W. Cotton, Esq.

Captain Huddart's attention was directed to the subject of rope-making, in consequence of observing every morning during a voyage that some of the external yarns of the cable were broken, even when it had undergone no very heavy strain.

The cause of the failure of the yarns soon became apparent, in that the strands being all of the same length, an additional strain was of necessity thrown on the external yarns by the process of twisting, when the internal yarns were kinched up.

This defect he proposed to obviate, by giving to each yarn an increased length in proportion to its distance from the centre of the strand, and the angle at which it was laid; for this purpose he invented a machine which he termed a register, which so regulated the length of the yarns as to make them, when twisted into a rope, all bear their due proportion of the strain.

The entirely satisfactory results attending Captain Huddart's experiments rendered him anxious to see his plan of rope-making tried on an extensive scale, and ultimately the partnership of Huddart and Co. was formed, and works at Limehouse were commenced and completed under his superintendence.

For many years the machinery was only employed in the construction of the strand, by which the great increase of strength was obtained, the rope being completed by hand in the usual manner by four gangs of men, three gangs giving what is termed the hard to the strands and keeping up the twist, as the other gang twisted them the other way into a rope; the correctness of this operation depending on all these gangs working with proportionate power and activity, it was frequently found that the strands were not laid in the rope with such accuracy as to allow each of them to bear its proper proportion of strain; and in order to render his plan of rope-making more complete, he designed the large laying machine, which effectually prevented the defects which it was difficult to avoid under the old system.

January 30, 1838. The President in the Chair.

On the relative Advantages and Disadvantages of Four and Six Wheels for Locomotives; by Edward Woods.

The engines at first introduced upon the Liverpool and Manchester Railway were found to be much too slightly constructed for sustaining the shocks and the strains to which their high velocities and the inequalities of the road continually exposed them; so that, after a short period, each individual engine required and underwent a thorough and general repair. These repairs consisted in the substitution of greater strengths and more approved forms of material, together with a mode of connexion of the parts better adapted to resist the repeated and periodical concussions. Thus the outer and inner framings were stayed—wooden wheels replaced with iron ones—crank axles constructed with nearly double the original quantity of materials—pistons, piston-rods, connecting rods, and brasses, were proportionably enlarged, until little remains of the old engine but its boilers and cylinders. The weight of the engine was increased, in consequence of these alterations, from about four and a half tons to nearly ten tons. The effect of this increased weight upon the road could not be otherwise than highly prejudicial, and the result was, that the road originally formed of rails intended to support a moving mass, not exceeding four and a half tons, distributed upon four wheels, was constantly out of repair, the rails being seriously bent, becoming loose, and frequently broken; so that it was found absolutely necessary to relay the whole line with stronger rails, and, as a temporary expedient, to substitute props under the rails between the points of support, and to add a third pair of wheels to the back part of the framing of the engine, behind the fire-box. The advantages obtained from the alterations, and the additional pair of wheels, were almost immediately apparent. The engine lost in a great degree its peculiar rocking motion, as also the unsteadiness arising from lateral undulations. Besides such direct and immediate results, time soon developed further consequences of an important nature, the component parts of the engine remaining for a much longer period securely united and firm, the fastenings of the tubes ceased to leak and give way, and the framings retained more permanently their fixtures, besides the increased safety in the diminished liability of the engine to run off the rails in the event of any accident. The author then considers the often-agitated question of an outside framing to the engines, and proceeds to the consideration of the principal objections against the use of six-wheeled engines, which objections are—1st, The less adhesion to the rails than four-wheeled engines; 2dly, That the axle and weight of the wheels adds to the resistance, and consequently detracts from the available power; and 3dly, That they cannot traverse curves without increased strain and friction. With regard to the first, it is true that the adhesion is less, adhesion being proportioned to the pressure; but the real question to be considered is, whether the ratio between the adhesion and the power of the engine is not sufficient for all practical purposes; and, from the working of the Liverpool and Manchester line, it appears that such is the case. To the second objection, Mr. Woods does not attach much importance, as the additional weight of a pair of wheels, axle, springs, &c., does not exceed 12 cwt., and, therefore, on a liberal estimate, cannot diminish the tractive power of the engine by 1-200th of the whole.

With respect to the third objection, the tendency to strain and friction in passing round curves, and the difficulty of taking the points, is entirely obviated by a very simple expedient. The plummer blocks of the hind wheels are made very light and elastic, so that they will yield readily sideways to an impression. For this purpose, it is found better to use small wheels, say three feet in diameter, that the plates may be long, and the axles at a considerable distance from the framing. Such methods render six-wheeled engines capable of travelling safely curves of eight chains radius, at a speed of 6 to 8 miles per hour; and an instance has occurred of a small curve of even four chains radius being passed at a slow speed.

On Improvements in Water Wheels; by Isaac Dodds.

The result of many experiments, with a view of lessening the bad effects produced

by the back-water upon the water-wheels on any sudden rise or flooding of the stream, had led Mr. Dodds to recommend the adoption of two air-vessels, which may press the sides or water-guides, and serve to carry the wheel; these, when properly ballasted, may raise or lower the wheel and the machinery, according as the water is higher or lower, the race being so adapted that the dam-head may be raised in the same proportion as the back-water.

February 13.

A Description of the French Method of Constructing Flat Roofs with Earthenware Pots; by F. W. Simms.

Mr. Simms having a short time since visited Paris, with a view to examine into the nature and various applications of the asphaltic mastic of Seysel, there extensively employed in the construction of foot-pavements, the covering of roofs, and other purposes, was led, in the course of his inquiries, to examine the construction of the roof of the Manutention des Vivres de la Guerre, Quai de Billy, which is formed of earthenware pots and coated with asphaltic mastic. The roof, which forms a terrace, is nearly flat, having just sufficient inclination to carry off the rain; the voussoirs of the flat arches are formed of cylindrical earthenware pots,* nearly resembling our chimney-pots, with the exception that both ends are closed, and one end being finished off nearly square. The dimensions of the pots vary with the size of the roof to be constructed; those used in the abovenamed roof are about nine inches long, and five inches in diameter. The thrust of the arches is resisted by iron bands and the external walls firmly tied together, and between them and the longitudinal middle wall the arches of the roof are turned with these pots set in mortar. The soffit of the arches being covered with plaster, form, without the intervention of timber, the ceilings of the upper apartments. The extrados of the arches is covered with beton, which is spread so as to give the required inclination for carrying off the water; this surface is afterwards carefully smoothed over with a thin coating of hydraulic mortar, which when dry is itself covered with canvass stretched tight; upon the canvass is poured the asphaltic mastic† in a semifluid state, which setting in a few minutes, forms the finished surface of the terraced roof. Mr. Simms details some facts showing the surprising strength of the roofs thus constructed, their durability, and their easy reparation when injured.

February 20.

Description of Clegg's Dry Gas Meter.

The meter invented by Mr. Clegg for measuring gas may be applied to other useful purposes, as the registering the average pressure of high pressure steam every hour, day, or all the year—the average temperature of heated air, as it leaves the boilers of steam-engines—or registering any variable temperature for any period.

The principle of action of the dry gas meter is the evaporation of spirits of wine, which is well known to vary *directly* as the heat.

To contain the spirits of wine, and to cause a perpetual action as long as the heat is applied, there are two glass globes, about 1 and ¾ inches diameter, ½ an inch apart, joined together by a glass tube of about ⅛ inch bore; these globes are balanced upon an axis, about which they can freely revolve; one globe is nearly filled with spirits of wine, and in the other is a perfect vacuum; these globes are suspended in a frame upon an axis, the gas from the main is then introduced by means of a pipe conducting it to the underside of a gas-burner placed over the globes, which is always lighted when the meter is in action, the gas in its passage is thereby heated, and then conducted by a continuation of the same pipe, terminating by two orifices of nearly equal area, the lower one being rather the largest. These orifices are opposite the centre of each globe; it is obvious, therefore, that the excess of heat would be on the lower globe, and, as the temperature of the burner above the meter varies, so would the excess of heat on the lower globe, and in this state would be useless, as the correctness of the meter depends upon an uniform temperature between the globes, whatever be the temperature of the source from whence it is derived. This uniformity of temperature is accomplished by another portion of gas, much colder than that portion which comes in contact with the burner, but still heated from the same source, blowing upon the upper bulb, this orifice exceeding the difference of area of the two orifices before mentioned, as the temperature of the gas in the lower orifice exceeds the temperature of the colder portion of the gas which is discharged upon the upper globe, so that, if the gas discharged upon the lower globe receives more heat from the burner, the portion of colder gas receives the same quantity of caloric, and counteracts the effect which would otherwise be produced.

It is then ascertained by actual measure what quantity of heated gas will cause the spirits from the lower globe to be driven into the upper one, and this once ascertained, is as much to be depended upon as the vibration of a pendulum.

The globes are so adjusted upon their axis that they remain at rest when one globe is over the other, but so far out of the centre of gravity, that when the spirits from the lower globe is discharged into the upper one, it will by its weight descend, thus causing a vibrating motion, these vibrations being registered by a train of wheel-work as in the water-meters.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an Ordinary General Meeting, held Monday, 29th January, 1838, Earl de Grey, President, in the chair, the following gentlemen were duly elected:—Charles James Richardson, Esq., as fellow; George B. Webb, Esq., and Charles Henman, Esq., as Associates.

Several donations were announced as having been received since the last Meeting:—A donation of £50 was announced as having been received from G. B. Greenough, Esq., together with a volume of the Transactions of the Geological Society. It was resolved, that G. B. Greenough, Esq., be transferred from the class of Honorary Fellows, and that the best thanks of the Institute be presented to him, for his munificent donation this evening, and that his name be entered on the list of benefactors.

A communication was read from H. E. Goodridge, Fellow, describing the ruins of a Roman villa recently discovered at Newton, near Bath.

Part of an essay, sent in for the Institute medal, on the following subject, was read:—"On the excellences which distinguish the ancient Athenian Architecture, and on the principles of art and science by which they were attained, with regard to design, proportion, light and shade, colour, construction and adaptation to purpose, to situation, and to the materials employed."

Mr. Joyce, of Camberwell, gardener, attended with one of his newly-invented stoves, and explained its general uses and applicability to various purposes.

A portrait of Her Majesty, by A. E. Chalon, Esq., R.A., and now engraving by S. Cousins, Esq., having been lent for exhibition by Mr. Moon, the publisher, was shown to the members and visitors, together with a proof of the engraving.

At a Meeting of the Members, on Monday, the 12th February, 1838; P. F. Robinson, V. P., in the chair, the Earl of Liverpool was duly elected an Honorary Fellow.

The following gentlemen were duly elected as Associates:—Frederick Humphrey, Groves, Esq., Samuel S. T. Carlow, Esq., and Wm. August Buckley, Esq.

Several donations were announced as having been received since the last meeting:—Dr. Moller, of Darmstadt, honorary and corresponding member, presented an engraved outline of the west front of Cologne Cathedral, published by him, with a description, 1837; Owen Jones, Esq., presented casts of two capitals of marble columns from the Alhambra.

The following papers were read:—

The conclusion of the paper on Athenian Architecture, commenced at the last ordinary meeting.

The History of Llanthony Abbey, in illustration of the drawings submitted for the Soane medallion.

The following Report of the Council, on the several essays and drawings sent in for the prize-medals, was read:—

"The Council report, that agreeably to the printed proposals issued, inviting candidates for the prize drawings and essays, that they received four sets of designs for the restoration of monasteries (viz.), two for the Abbey of St. Mary, at York, distinguished by the motto, "*Ut Rosa flo florum sic est Domus ista Domorum*," and "*Quod potui, perfeci*," another for Llanthony Abbey, Monmouthshire, marked, "*Caveat successibus opto quisquis ab eventu facta notanda putat*," and the fourth for Kirkstall Abbey, Yorkshire, with "*Valeat quantum valere potest*," also two essays on the subject of Greek architecture, with the mottos of "Ακαταξεστος," and "*Qualem nequeo monstrare et sentio tantum*;" and one on the polychromy of Gothic architecture, with the device of a triangle inscribed in a circle.

"That, after a careful examination of the drawings and descriptions, the Council have come to the unanimous conclusion, that the design for the restoration of St. Mary's Abbey, York, with the motto "*Ut Rosa &c.*," is the best, and that the author is therefore entitled to the Soane medallion. Also that the design for the restoration of Llanthony Abbey possesses so much merit, that it is very desirable to mark the approbation of the Institute by a premium. And although only the Soane medallion was held out for competition, that a *secondary medal* should be awarded to this production, they accordingly recommended that a Medal be struck from the Institute die, having the wreath on the obverse, and the reverse plain; so as to receive an inscription recording the occasion of its presentation, and that such a medal be given to the author of the restoration of Llanthony Abbey.

"With respect to the essays the Council have unanimously agreed, that the paper distinguished by the motto "Ακαταξεστος," is the best, and that the author is deserving of the Institute medal proposed for that subject.

(Signed) "G. L. Taylor, Chairman."

The recommendation of the Council, as to the adjudication of the several medals, was confirmed.

The letters bearing the mottos of the successful essay and drawings having been opened, the authors appeared to be as follows:—

William W. Pocock, associate, of the essay on Athenian Architecture.

Samuel Sharp, associate, of York, of the restoration of St. Mary's Abbey.

Mr. George Edward Laing, of No. 5, Charlotte-street, Bloomsbury, of the restoration of Llanthony Abbey.

The subjects for the prize medals for the year 1839 were announced—for particulars see Advertisement.

The following being recommended by a Minute of Council of the 8th instant, as proper subjects for the prize medals of the year 1839, Resolved, that the same be the subjects accordingly, viz.:—

"On the peculiar characteristics in design and construction which distinguished Roman from Grecian Architecture, as evinced in their works.

"On the various modes that have been practised in forming artificial foundations of buildings, and their results in different soils and situations, naturally difficult or defective, with a view to deduce the proper principles of construction in these respects.

"On the practical application of the theory of sound in the construction of edifices, by which the principles may be ascertained for building theatres, churches, halls, and other places for public meetings, in the manner most favourable for the transmission of sound.

"The restoration of some ancient baronial castle in England, Scotland, or Ireland, such as Conway, Caernarvon, Bamborough, Corfe, or Warkworth Castles, with the several courts, halls, chapels, keeps, and dependencies, to be drawn from actual measurement, distinguishing in a marked manner the parts existing from those restored to complete the combination, accompanied by a description."

ROYAL INSTITUTION OF BRITISH ARCHITECTS.

To the Right Honourable the Lords Commissioners of Her Majesty's Treasury.

The humble Memorial of the President, Council, and other Members of incorporated Institute of British Architects,

Sheweth—That the Institute has been incorporated under a charter granted by his late Majesty King William the Fourth, for the purpose of facilitating

* This method of forming arches has been adopted in England for many years; several of the roofs at the Bank are thus constructed.—*Editor C. E. & A. Journ.*

† We gave some account of the asphaltic mastic or cement in the Journal, No. 4, page 90; a full account of its various applications is given in a small pamphlet by Mr. Simms, entitled "Practical Observations on the Asphaltic Mastic, or Cement of Seyssel."—Editor.

the acquirement and diffusion of architectural knowledge, for the promotion of the different branches of science connected therewith, and for the establishing a uniformity and respectability of practice in the members of the profession; thus embracing many objects, which may justly be deemed of very great importance to a nation, considering the influence which public monuments are calculated to exercise upon the character of the people.

That her present Majesty has graciously been pleased to become the patroness of the Institute.

That your Memorialists have already published the first volume of their Transactions, which has been favourably received, so as to render necessary the publication of a second edition. The most celebrated architects of foreign countries have been associated as honorary and corresponding members, by which means an extensive correspondence has been established with various parts of the globe.

That since the original formation of this Institute a considerable collection of books, casts, models, prints, and drawings has been made, to such an extent that the members are not able to provide sufficient accommodation for the reception of the collection, and holding its meetings in a convenient and respectable part of the metropolis, without incurring a rent, to which the funds are inadequate.

That the Institute is, as your Memorialists firmly believe, well calculated to exercise the most beneficial influence upon the practice of civil architecture in this country; which consideration, taken in connexion with the progress that has been made under the auspices of his late Majesty and our present most gracious Sovereign, in placing the Society upon a permanent footing, leads its members to entertain a confident hope that the Government of the country will extend its fostering protection and countenance, as in the case of other societies having objects certainly not more important to the community, and be induced to afford the Institute of British Architects apartments for holding its meetings, and depositing the collection which it already possesses, and which it may acquire.

That your Memorialists trust your Lordships will be pleased to allot apartments in Somerset House, or in some other public building, for the purposes aforesaid, as such accommodation would very greatly tend to render this Institute permanently and more extensively useful, and no less honourable to the nation as a public institution.

Your Memorialists therefore humbly pray your Lordships to take the above statement into consideration, and to afford to this Society the important assistance above referred to.

And they will ever pray, &c.

Signed by HIS LORDSHIP, THE PRESIDENT, AND THE OTHER MEMBERS OF THE COUNCIL, AND WITH THE CORPORATE SEAL ATTACHED.

Treasury Chambers, Feb. 13, 1838.

My Lord and Gentlemen—Having laid before the Lords Commissioners of Her Majesty's Treasury your Memorial, in which you pray that apartments may be provided for the use of the Institute of British Architects at Somerset House, or elsewhere, I am commanded by their Lordships to acquaint you in reply, that with every disposition to forward the useful objects which the Society seeks to attain, my Lords have it not in their power to provide apartments for the use of the Society. I have the honour to be, my Lord and Gentlemen, your obedient servant,

To the President, Council, and Members of the Institute of British Architects. A. GROSVENOR.

MEETINGS OF SCIENTIFIC SOCIETIES.

Institution of Civil Engineers, 1, Cannon-row, Westminster, every Tuesday evening, at 8 o'clock.

Royal Institute of British Architects, 16, Grosvenor-street, Grosvenor-square, Monday Evening, at 8 o'clock, February 12th and 26th. Lectures, February 8, 12, 15, 22, and 26th, at 8 o'clock.

Architectural Society, 35, Lincoln's-inn-fields, Tuesday, March 13th, at 8 o'clock.

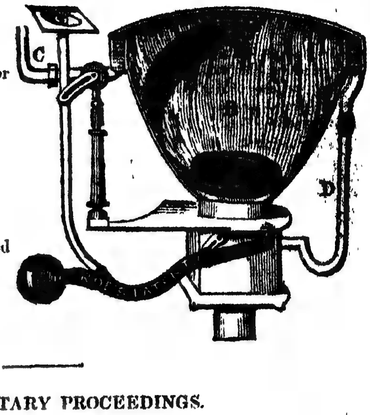
Society of Arts, Adelphi, every Wednesday, at 8 o'clock. Illustration Tuesday, March 13th.

ARCHITECTURAL SOCIETY.

Tuesday, January 30, 1838.—The usual meeting was held, J. Wooley, Esq., in the chair. The balloting for the students' drawings then took place; after which the following paper, by William Wallen, Jun., Esq., member, was read:—"On Prejudice as to style in Architecture." Mr. Fox exhibited several specimens of coloured and embossed glass, which excited much interest from their excellence and cheapness; they are deserving of the attention of the profession. The subjects for the members' and students' sketches were then given out, and the meeting adjourned.

Tuesday, February 13, 1838.—The usual monthly meeting was held, W. B. Clark, Esq., the President, in the chair. A paper was read by John Blyth, Esq., a member, on "The Necessity of a National School of Architecture."

Mr. Roe exhibited his patent water-closet apparatus, and explained the improvement and superiority over those now in use. The following are its advantages:—It is not necessary to have the complicated apparatus which is attached to the common closet, viz., water-box, valves, lever, cranks, or wires, and a separate pipe to each closet, and frequently a cistern also; Mr. Roe's closet, no matter how many there are in a building, can be supplied from one cistern (if it be above the highest closet), and one main pipe, with branches to the several closets. The principal improvement seems to be, that instead of the common stool-cock, the patentee has invented a conical valve cock, that is opened by lifting a handle (in the seat), as in the present closet. There is also an improvement in the basin: round the rim is a small chamber, with an aperture all round the pan, from which, in addition to the fan at the back, the water flows immediately the valve cock is opened, and completely cleanses the pan, as shown in the annexed figure.



A Recess reserving the after supply for bottom of basin.

B Basin with recess overflowing.

C Supply-pipe from cistern.

D Overflow-pipe. This pipe is charged every time the closet is used.

PARLIAMENTARY PROCEEDINGS.

FEB. 5.—*Thomas Parkin.*—Petition of Thomas Parkin, complaining of the infringement of his patent for improving the construction of railways, by the London and Croydon Railway Company; ordered to lie on the table.

Farringdon Street, London.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Soane's Museum.—Statement of the Funds of the Museum on 5th January, 1838, presented (by act); to lie on the table.

Public Monuments.—Return presented, of Monuments erected in Westminster Abbey and St. Paul's at the public expense, from 1750 (ordered 21st December); to lie on the table.

Gloucester Water-works.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Belfast Water-works (No. 2).—Petition for Bill referred to the Select Committee on Petitions for Private Bills.

FEB. 6.—*London and Greenwich Railway.*—Petition for Bill reported, and Bill ordered to be brought in by Mr. Wolverley Attwood and Mr. Barnard.

Manchester, Bolton, and Bury Canal and Railway.—Petition for Bill reported, and Bill ordered to be brought in by Mr. Wilson Patten and Lord Viscount Sandon.

Newcastle-upon-Tyne and Carlisle Railway.—Petition for Bill reported, and Bill ordered to be brought in by Mr. Ord and Mr. Philip Howard.

Gravesend Pier.—Petition for Bill reported, and Bill ordered to be brought in by Sir M. Wood and Sir W. Geary.

Tenby Improvement.—Petition for Bill reported, and Bill ordered to be brought in by Sir John Owen and Mr. Owen.

FEB. 7.—*Gravesend Pier Bill.*—"For preventing the partial collection of certain tolls and rates granted for the erection and support of Gravesend Quay and Pier," presented; read first time; to be read a second time.

Festiniog Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Brandling Junction Railway.—Petition for Bill reported, and Bill ordered to be brought in by Mr. Ingham and Mr. Bell.

London and Greenwich Railway Bill.—"For extending the time for completing the London and Greenwich Railway, and for amending the Act relating thereto," presented; read first time; to be read a second time.

Metropolis Cemetery.—Petition for Bill reported; report ordered to lie on the table.

Anti-Dry-Rot Company.—Petition for Bill reported; report ordered to lie on the table.

FEB. 8.—*Midland Counties (Mountsorrel) Railway.*—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Ramsgate Improvement.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Petitions for Private Bills Committee.—Power to send for persons, papers, and records.

FEB. 9.—*Newcastle-upon-Tyne and Carlisle Railway Bill.*—"To authorize the Newcastle-upon-Tyne and Carlisle Railway Company to raise an additional sum of money for the purposes of their undertaking," presented; read first time; to be read second time.

Edinburgh and Glasgow Railway.—Petition in favour of the application; ordered to lie on the table.

Southampton Pier.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Necropolis Cemetery.—Report [7th February] read; Bill ordered to be brought in by Mr. Phillpotts and Sir Matthew Wood.

Fishguard Harbour.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Eastern Counties Railway.—Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

London and Croydon Railway (No. 1).—Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

Tenby Improvement Bill.—"For the Improvement of the Borough of Tenby, in the County of Pembroke, and for regulating and maintaining the Harbour and Pier belonging thereto; presented and read first time.

Montgomeryshire Western Branch Canal.—Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

FEB. 12.—*Necropolis Cemetery Bill.*—"For incorporating a Company, to be called the 'Necropolis Cemetery Company;' and for enabling such Company to establish

a Cemetery for Interment of the Dead in the vicinity of the metropolis;" presented; read first time; ordered to be read a second time.

Grand Junction Railway.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Aberbrothwick Harbour.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Bristol and Exeter Railway.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Swansea Harbour.—Petition for Bill; referred to Select Committee.

Edinburgh and Glasgow Railway.—Petition of the Provost, Magistrates, and Town-Council of Bathgate, against the application; referred to the Select Committee on Petitions for Private Bills.

Cheltenham and Great Western Union Railway.—Petition for Bill reported; report referred to the Select Committee on Standing Orders.

Soane's Museum.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Metropolis Improvements.—Order [21st December] for appointing a Select Committee read, and discharged. Select Committee appointed, "to take into their consideration the several Plans for the Improvement of the Metropolis, concerning which a Report was made to this House by a Committee in the year 1836, together with any other Plans for the same object, which they may deem deserving of consideration, and to report their opinion as to the expediency of adopting any of the said improvements, and also as to the best means of carrying the same into effect:—Sir Matthew Wood, Mr Chancellor of the Exchequer, Sir Robert Peel, Lord Viscount Lowther, Mr. Herries, Admiral Codrington, Sir Robert Harry Inglis, Mr. Shaw Lefevre, Mr. Wakley, Colonel Evans, Mr. Clay, Mr George Palmer, Mr. Pendarves, Mr. Barnard, Mr. Hall.—Power to send for persons, papers, and records; Five to be the quorum.—Report from Select Committee on Metropolis Improvements [2d August, 1836] referred.

FEB. 13.—*Bury* (Lancaster) *Water-works.*—Petition for Bill; referred to Select Committee.

Edinburgh and Glasgow Railway.—Petition for Bill reported, Report referred to Select Committee on Standing Orders

Gairnkirk and Glasgow Railway.—Petition for Bill; referred to Select Committee.

Newquay (Cornwall) *Harbour.*—Petition for Bill, referred to Select Committee

Newtyle and Coupar Angus Railway.—Petition for Bill, referred to Select Committee.

Oldham Gas Light and Water works.—Petition for Bill; referred to Select Committee.

West India Docks.—Petition for Bill; referred to Select Committee.

Ribble Navigation.—Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

Turton and Entwistle Reservoir.—Petition for Bill, referred to the Select Committee on Petitions for Private Bills.

Standing Orders Committee.—Resolution reported.—"That, in the case of the Leominster Improvement Petition, the parties be permitted to proceed with their Bill, on inserting the Notice in three successive *London Gazettes*; and that the Committee on the Bill do examine, in the first place, how far such Order has been complied with, and do report the same to the House on the Report of the Bill" Resolution agreed to.

Moy River Navigation.—Petition for Bill, referred to the Select Committee on Petitions for Private Bills.

FEB. 14.—*Gravesend Cemetery.*—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Brandling Junction Railway Bill.—"To enable the Brandling Junction Railway Company to raise an additional sum of money," presented, read first time, to be read second time.

Isle of Thanet Cemetery Bill.—Petition for Bill, referred to Select Committee.

Southampton Docks.—Petition for Bill; referred to Select Committee.

Newcastle-upon-Tyne and North Shields Railway Extension.—Petition for Bill, referred to Select Committee.

Blackburn Gas.—Petition for Bill; referred to Select Committee.

FEB. 15.—*Edinburgh and Glasgow Railway.*—Seventeen Petitions in favour of the application; ordered to lie on the table.

London and Brighton Railway Act.—Petition of James Mills, praying for the repeal of the said Act, and that the House will allow the subscribers to Mills's line of Railway, who have deposited plans, &c., in conformity with the Standing Orders, to proceed with their Bill during the present Session; ordered to lie on the table.

Severn Navigation.—Petition for Bill, referred to Select Committee on Petitions for Private Bills.

Taw Vale Railway and Dock.—Petition for Bill, referred to Select Committee on Petitions for Private Bills.

Paington Harbour Bill.—Reported, and re-committed to former Committee; leave to sit and proceed, and to report on Monday next.

St. Helen's and Runcorn Gap Railway.—Petition for Bill, referred to Select Committee on Petitions for Private Bills.

Bolton and Preston Railway.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

Grand Junction Railway.—Petition for Bill; referred to Select Committee on Petitions for Private Bills.

FEB. 16.—*Tyne Dock.*—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Sudbury Water-works and Improvement.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Severn Navigation (No. 2).—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Hartlepool Dock and Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Portland Cemetery.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

West Durham Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Ardrossan Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Metropolitan Suspension Bridge.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

Thames Improvement Company and Drainage Manure Association Bill.—"To incorporate a Company by the name of the Thames Improvement Company and Drainage Manure Association," presented and read first time; to be read second time.

Birmingham, Bristol, and Thames Junction Railway.—Petition for Bill; referred to the Select Committee on Petitions for Private Bills.

FEB. 19.—*Paignton Harbour (re-committed) Bill.*—Reported; to lie on the table.

Milton next Sittingbourne Improvement Bill.—Read third time, and passed.

Manchester, Bolton, and Bury Canal and Railway Bill.—"For enabling the Company of Proprietors of the Manchester, Bolton, and Bury Canal Navigation and Railway to raise more money; and for amending the powers and provisions of the several Acts relating thereto," presented and read first time; to be read second time.

Standing Orders Committee.—Resolutions reported and agreed to:—"That in the case of the Montgomeryshire Western Branch Canal Petition, the parties be permitted to proceed with their Bill."—"That, in the case of the Eastern Counties Railway Petition, the parties be permitted to proceed with their Bill."—"That, in the case of the Cheltenham and Great Western Railway Petition, the Standing Orders be dispensed with, except in the deviation exceeding one mile proposed to be made in the tunnel at Sapperton, and that they be dispensed with in this case also, on the parties producing to the Committee on the Bill the consent of the owners or reputed owners, lessees or reputed lessees and occupiers of the land under which the tunnel is to pass, and that the Committee on the Bill do report to the House how far such Order has been complied with, on the Report of the Bill."—"That in the case of the London and Croydon Railway Petition, the parties be permitted to proceed with their Bill, on proving to the Committee thereon, that the sum of 800l., being one-tenth part of the amount subscribed, now deposited under seal in the banking-house of Messrs. Jones, Lloyd, and Co., Lothbury, remains so deposited; and that the Committee on the Bill do report to the House how far such Order has been complied with, on the Report of the Bill."—"That, in the case of the Edinburgh and Glasgow Railway Petition, the parties be permitted to proceed with their Bill, on proving to the Committee thereon that a deposit of ten per cent. on the amount subscribed is made as required by the Standing Orders; and that the Committee on the Bill do report to the House how far such Order has been complied with, on the Report of the Bill."

Cheltenham and Great Western Union Railway.—Report (this day) from Select Committee on Standing Orders, read; Bill ordered to be brought.

FEB. 20.—*Glasgow Water-works.*—Petition for Bill reported, and Bill ordered to be brought in

Cheltenham and Great Western Union Railway Bill.—"To alter the Line of the Cheltenham and Great Western Union Railway, and to amend the Act relating thereto," presented, and read first time, to read second time.

London and Croydon Railway.—Report (19th February) from Select Committee on Standing Orders read; Bill ordered to be brought in.

London and Greenwich Railway Bill.—Read second time, and committed.

FEB. 22.—*Festiniog Railway.*—Petition for Bill reported; Report to lie on the table.

Farringdon Street (London). Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

Midland Counties (Mountsorrel) Railway.—Petition for Bill reported; Report referred to the Select Committee on Standing Orders.

Southampton Pier. Petition for Bill reported, and Bill ordered to be brought in.

FEBRUARY 23.—*Eastern Counties Railway.* Report [19th February] from Select Committee on Petitions for Private Bills read; Bill ordered to be brought in.

London and Croydon Railway (No 1) *Bill.*—"to enable 'The London and Croydon Railway Company' to enlarge their station in the parish of St. Olave, in the borough of Southwark in the county of Surrey, and to amend the Acts relating to said Railway and Station, presented and read first time, to be read second time.

Anti Dry Rot Company.—Report [7th February] from Select Committee on Petitions for Private Bills read, Bill ordered to be brought in.

London and Greenwich Railway Bill.—Petition for additional provision; referred to the Select Committee on Petitions for Private Bills.

LAW PROCEEDINGS.

Middlesex Sittings, at Nisi Prius, before the Lord Chief Justice of the Common Pleas and a Special Jury.

INFRINGEMENT OF A PATENT.—JONES *v.* HEATON AND OTHERS.

This was an action for the infringement of a patent obtained by the plaintiff, who was a machine manufacturer at Birmingham, *for certain improvements in the machinery for moulding bricks, tiles, and other articles made of brick-earth*, to which there were several pleas. First, that the plaintiff was not the true and first inventor; secondly, that the specification did not sufficiently describe the manner in which the invention was to be carried into effect; and thirdly, that the alleged invention was not, before the granting of the patent, perfect and complete.

Mr. Sergeant Wild and Mr. Watson appeared for the plaintiff, and Mr. Sergeant Talfourd and two other learned gentlemen for the defendants.

The cause occupied the court two days, and it appeared in evidence that the plaintiff obtained his patent in August, 1835, and that on the 10th of February following, the specification was enrolled. That specification pointed out the principal features of novelty in the machine to be an inclined plane, at the top of which the bricks were delivered, and pistons to force the bricks up the track of that inclined plane; and the defendants, to support the case—which was, that they had invented and used a machine on that principle previously to the granting the patent—called witnesses to prove, that one of the defendants, in a consultation with his son-in-law, held in March, 1835, had described and sketched such a machine from his own invention; that in the following June he had exhibited a model of it to another son-in-law; that he had, in June or July, employed some persons in the manufacture of the machine, which was now used by the defendants and complained of by the plaintiff; that in January, 1836, it was used for the purpose of experiment, but only to a small extent; that at the end of January or beginning of February (no more precise date being given) the Excise-office of Birmingham saw the machine in operation, and a small number of bricks made by it, but that it

was not brought into regular work until the month of April, 1836. That was the substance of the evidence for defendants on the first issue; on the other issues, scientific men were called to speak to the sufficiency of the specification, but upon that, the usual difference of opinion existed—Mr. Bramah, on the one side, thinking it amply sufficient, and Mr. Farey, on the other, regarding it as wholly insufficient; the one gentleman considering the plaintiff's invention very valuable, the other deeming it almost utterly useless. It appeared further, that the specification embraced two machines, the one square and the other circular; and with a view to show that subsequent to the date of the patent the plaintiff had altered his notion of the machine, and substituted the circular one for the square, defendants endeavoured to prove that the articles used at first were applicable only to the square one, which had not been used by defendants, and was not, therefore, in dispute; but it was urged on the part of the plaintiff, that the two machines were described in two different and distinct parts of the specification, and that the plaintiff was fully entitled to maintain both.

The Lord Chief Justice, in summing up the case, told the Jury, that in order to establish the point that the plaintiff was not the first and true inventor, it was necessary that they should be satisfied that there had been a public user of the machine previous to the date of the patent.

Verdict for the plaintiff on all three issues.

RATING OF RAILWAYS TO THE POOR RATE.

An important appeal was tried at the last Kirkdale Sessions. The Grand Junction Railway was rated in the township of Newton at £1,800 per mile per annum. It was admitted that the traffic on that particular part of the line was greater than on any other. The parish contended, that the gross annual value was £1,659 per mile in the township, and the value to let in the same £1,231, deducting 20 per cent. for tenant's profits, and for maintaining the railway; and £70 for parochial charges. It was proved that the gross toll on the Warrington and Newton line had been £640 per mile, the cost of repairs £57, and the parish proposed to double that allowance on the Grand Junction. For the appellants it was contended, that from the gross produce ought to be deducted the general expense of maintaining the railway, police, engineers, &c., reducing the "full annual value to let," on their showing, to £827 per mile. The magistrates had a long consultation, and, we understand, a protracted discussion as to the different facts. At a late hour they gave their decision, allowing £20 per cent. for profits of a supposed lessee; £300 (instead of £150) per mile, for maintenance of way, &c.; and the £70 for parochial charges. The result of the appeal thus being in figures, that the appellants will have to pay £14 17s. instead of £27 7s. 6d., the amount of the rate at 4d. in the pound, on two-thirds "the net annual value to let"—the rates on all other property in this township being only on two-thirds.

COMPENSATION CAUSES.—HULL CORPORATION v. THE RAILWAY COMPANY.

The case which was brought at the instance of the Corporation of Hull against the Hull and Selby Railway Company, for the purpose of ascertaining the value of the land belonging to the corporation required for the purposes of the Railway, was tried in the Court Room, at the Mansion House, on Saturday, the 3rd ult.; Mr. Matthew Davenport Hill and Mr. Reynolds appeared as counsel for the plaintiffs, and Mr. Baines and Mr. Hildyard for the defendants. A number of witnesses were examined as to the value of the lands in dispute; and after a long and tedious investigation, which occupied the whole of the day, the jury assessed the damage due to the corporation for the loss of the land at £3,675 17s. The case was heard before Mr. Thorney, the coroner's assessor. The result of the trial at Beverley, which lasted two days, between the trustee of the late Mr. A. Atkinson, of Dairycoates, and the Hull and Selby Railway Company, is as follows:—

Demand made on the company	£6,574	0	0
Offer made by the company	1,850	0	0
Verdict of the jury	1,810	0	0

The trial between Mr. Spicer, of Hessle, and the Company, came on also at Beverley, and occupied the whole of Thursday, the 8th ult., ending in the following result:—

Demand made on the company	£2,500	0	0
Offer made by the company	1,073	15	0
Verdict of the jury	1,070	0	0

The verdicts being below the offers, half the costs of the Company will have to be paid by the claimants.

THE LEEDS AND MANCHESTER RAILWAY v. MR. HENRY TAYLOR.

An inquiry to assess damages under the Leeds and Manchester Railway Act, took place before a jury specially summoned for the purpose, on Friday, 2nd ult., at the Coach and Horses, St. George's-road. The party for taking whose land damages were assessed, was Mr. Henry Taylor, of Pontefract. The land required is situated in the vicinity of St. George's Church. No offer had been made on the part of the company. Evidence was adduced on the part of Mr. Taylor, to prove that the property might be rendered very valuable for wharfing purposes, as it was near a branch of the Rochdale canal, which might, without much difficulty, be brought into Mr. Taylor's land, and several valuers were called to prove the value of the land, the average of whose valuation was about 1s. per yard, at twenty years' purchase. For wharfing purposes the land was valued at £44,000., and for building upon, at £24,000. The valuers called on behalf of the Railway, valued the land at £15,000, or thereabouts, and the jury, after being charged by the assessor, gave £17,000. The costs on both sides to be paid by the Railway Company, and the price awarded averages 4½d. per yard, at twenty years' purchase on the whole quantity of land taken. The counsel for the Railway Company were Mr. Creswell, Mr. Brandt, and Mr. Wilkins; and for Mr. Taylor, Sir F. Pollock, Mr. Foster, and Mr. Duck. The case occupied the whole of the day.—From the *Manchester Courier* of Saturday, Feb. 7th.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 25TH JANUARY, AND THE 24TH FEBRUARY, 1838.

WILLIAM BATE, of Werrington, Northampton, Esq., for "Certain Improvements in obtaining and regulating Power."—27th January; 6 months.

MATTHEW HEATH, of Furnival's Inn, London, Esq., for "Improvements in Engines to be worked by Steam and other Fluids, being a communication from a foreigner residing abroad."—27th January; 6 months.

CHARLES FLUDE, of Long Lane, Bermondsey, Surrey, Manufacturing Chemist, for his "Invention of Improvements in applying Heat to the manufacture of Alkalies and Salts, and for smelting and otherwise working Ores, Metals, and Earths."—30th January; 6 months.

CHARLES PHILLIPS, of Chipping Norton, Oxford, Surgeon, for "Improvements in Apparatus or Machinery for punching, bending, cutting, and joining Metal, and for holding or screwing Metal to be punched, bent, cut, or otherwise operated on; parts of which Machinery are adapted to perform some of these operations on other Materials."—30th January; 6 months.

JOHN BARNETT HUMPHREYS, of Southampton, Civil Engineer, for his "Invention of Improvements in Marine and other Steam Engines."—30th January; 6 months.

DAVID WILKINSON SHARP, of Bingley, York, Worsted Spinner, for "Certain Improvements in Machinery or Apparatus for Warping worsted, linen, cotton, silk, or woollen Yarns."—30th January; 6 months.

GEORGE RYDER PEPPERCORNE, of Vauxhall, Surrey, Gentleman, for an "Improved Machinery to be employed for Locomotion on Railroads and other Roads, which is also applicable to other Engines for exerting Power."—31st January; 6 months.

WILLIAM HOLME HEGINBOTHAM, of Stockport, Chester, Gentleman, for "Certain Improvements in the construction of Gas Retorts."—31st January; 6 months.

GEORGE CHARLTON, of Wapping, Middlesex, Master Mariner, for "Improvements in Anchors, Capstans, Windlasses, and means of mooring and riding Ships at Anchor."—8th February; 6 months.

JOHN MELVILLE, of Upper Harley Street, Middlesex, Gentleman, for "Improvements in the generation of Steam, and on the application of Steam to Navigation."—8th February; 6 months.

JEROME DEVILLE, of Crutched Friars, London, Coach-builder, for "Certain Improvements in Railroads, and in the Carriages to be used thereon."—8th February; 6 months.

ROBERT ESSEX, of St. Mary, Islington, Middlesex, Silversmith, for "Certain Improvements in the construction of Paddle Wheels, and in the Paddle Boxes or Cases of Steam Vessels."—8th February; 6 months.

JAMES DUTTON, of Wotton-under-edge, Gloucester, Clothier, for "Certain Improvements in the manufacture of woollen Cloth, which Improvements apply both to weaving and dressing of woollen Cloth."—8th February; 6 months.

WILLIAM FARQUHAR, of George Street, Tower Hill, London, Chronometer-maker, for "Improvements in generating Steam for Steam Engines."—13th February; 6 months.

JOHANN GOTTLOBB SEYRIG, of Paris, in the kingdom of France, Mechanician, now of Old Compton Street, Soho, Middlesex, for "Certain Improvements in expressing or extracting Liquids or Moisture from woollen, cotton, and other stuffs and substances, either in a manufactured or unmanufactured state."—16th February; 6 months.

JOSEPH ERICSSON, of Berkeley Street, Connaught Square, Middlesex, Civil Engineer, for an "Improved Steam Engine."—16th February; 6 months.

JOHN JACKSON, of Kersley, Lancaster, Joiner and Cabinet-maker, for "Certain Improvements in sawing, planing, tongueing, and grooving, and otherwise preparing or constructing Window Sashes, Door and other Frames, Cornices, Mouldings, and various other Fittings or ornamental Wood Work; and in Machinery, Tools, or Apparatus to be used in the same."—16th February; 6 months.

EUGENE RICHARD LADISLAS DE BREZA, late of Paris, but now of St. Martin's street, Leicester-square, Gent., for a "Chemical combination or compound for rendering cloth, wood, paper, and other substances indestructible by fire, and also preserving them from the ravages of insects."—Feb. 20; 6 months.

JEREMIAH GRIME, of Bury, Lancaster, engraver, for "Certain Improvements in manufacturing wheels which are applicable to locomotive engines, tenders, and carriages, and to running wheels for other useful purposes, and also in the apparatus for constructing the same."—Feb. 21; 6 months.

JOHN CLAY, of Cottingham, near Hull, York, merchant, SAMUEL WALKER, of Millshaw, near Leeds, cloth manufacturer, and FREDERICK ROSENBERG, of Hull, for "Certain Improvements in machinery or apparatus for shearing or cropping, and dressing and finishing woollen and other cloths."—Feb. 22; 6 months.

EDWARD STOLLE, of Arundel-street, Strand, Esq., for "Improvements in making sugar from sugar cane, and in refining sugar."—Feb. 21; 6 months.

MOSES POOLE, of Lincoln's-inn, Middlesex, Gent., for "Improvements in preserving wine and other fermented liquids in bottles, being a communication from a foreigner residing abroad."—Feb. 24; 6 months.

JOHN HOULSTON, of Bradford, York, printer, for "Improvements in apparatus for stopping or retarding carriages."—Feb. 24; 6 months.

AMBROISE ADOR, of Leicester-square, Middlesex, chemist, for "Certain Improvements on lamps or apparatus for producing or affording light."—Feb. 24; 6 months.

JOHN THOMAS BETTS, of Smithfield Bars, London, Rectifier, for "Improvements in the manufacture of Gin, which he intends to denominate Betts' Patent Gin, or Betts' Patent Stomachic Gin, partly communicated by a foreigner resident abroad."—24th February; 6 months.

MICHAEL WHEELWRIGHT IVISON, Silk Spinner, Hailes Street, Edinburgh, for "An Improved Method of Consuming Smoke in Furnaces and other places where fire is used, and for Economising Fuel; and also for applying Air, heated or cold, to Blasting or Smelting."—24th February; 6 months.

STEAM NAVIGATION.

New Steam Shipping Company.—We understand the Marquis of Breadalbane, with that public spirit so peculiarly characteristic of his lordship, has entered warmly into the proposal for establishing a direct communication between Perth and London by steam, and has subscribed for shares in the concern to a large extent. Mr. Kinnaird, the member for the city, is also giving the project his strenuous support, and has taken a considerable number of shares of the stock.—*Perth Courier.*

We understand, that at a meeting of the partners of the Aberdeen and Hull Shipping Company, it was unanimously resolved, in order to meet the increasing trade betwixt this port and Hull, to introduce a powerful steam-vessel into their trade. We have no doubt the additional accommodation thus afforded the public will be duly appreciated, and that the company will have no cause to regret the resolution they have come to.

Steam Navigation.—A parliamentary paper, just published, show that steam navigation is making progress in all parts of Europe. It consists of returns from the British Consuls stationed at the principal trading towns, dated generally in the autumn of 1836. From this we find that five steamers, from 50 to 200 tons each, are employed in the intercourse between the ports of Denmark. In the ports of Sweden twenty-seven, but only from 15 to 100 tons burden; the speed from five to eight miles an hour. In the ports of Russia twenty-six, speed from six to ten miles. In those of Prussia only three. Rostock has one; Lubec two; Hamburgh three. Amsterdam has three. Rotterdam has twenty-six, of which thirteen ply on the Rhine between Rotterdam and Cologne; they are from 75 to 100 tons burden; the Antwerp and Ghent have three. In France—Havre has seventeen, of which two are sea-boats, and fifteen ply on the Seine; Brest has one steam-boat; Nantes has twenty-one, which chiefly ply on the Loire, some to Angers, others to Orleans, 250 miles from the sea; several of them draw only thirteen or fifteen inches water. This river is the chief seat of steam-navigation in France. Rochelle has two, and Bordeaux sixteen; Marseilles and Toulon have twelve. France had in all sixty-nine steam-boats in 1836. Spain and Portugal have each four steam-boats. Sardinia has five, Tuscany one, Naples eight, and Austria six.

Steam Navigation to India by the Cape of Good Hope.—We have learnt that a body of influential gentlemen, under the chairmanship of Captain Sir John Ross, have formed a company for building steam-vessels of twelve hundred tons, which can make the voyage to India by the Cape, carrying between six and seven hundred tons of merchandise, in the almost incredible short space of fifty-two days, with only one stoppage for fuel; and that the apparatus (a newly-invented boiler, by Mr. Collier) has been tried in a voyage made by Sir John, the result of which more than justified the expectations held out by the inventor.—*Morning Post.*

Steam between the Tyne and the Tay.—The Shields and Newcastle General Steam Navigation Company, to render complete and satisfactory the accommodation of their beautiful steam-vessels, which they have run so successfully on the Leith and Hull stations, have purchased the splendid steamer Northern Yacht, so much admired on the Scotch coast, as the most able and fast-sailing vessel in the kingdom. Early in the spring, she will commence running regularly between the Tyne and Dundee.—*Sunderland Herald.*

Two iron steamers are at present building to convey passengers from the pier at Hungerford-market, in the spring, down the river. They are to be on a large scale, and fire-proof.

PROGRESS OF RAILWAYS.

Eastern Counties Railway.—The contract for the iron bridge over the Regent's Canal, on this line, for which tenders were lately advertised, has been obtained by Messrs. B. and N. Sherwood, of Lambeth—sum 2,478*l.* The iron work is, we understand, to be supplied by the Horsley Company. The successful competitors for the supply of the rails (parallel) and chairs, for the portion of the line between Mile End and Ilford, are Messrs. Joseph and Crawshay Bailey, of the Nanty-glo Iron-works, and Messrs. Guest, Lewis, and Co., of the Dowlais Works. The Messrs. Bailey are to supply 1,000 tons at 12*l.* 2s. 6d. per ton, deliverable in the Thames. The iron is to be equal to the best No. 3 bar-iron, to be made wholly of pure or mine-iron, puddled and hammered and rolled into bars, cut up, again heated, and rolled into rails. Messrs. Bailey have also contracted to supply the chairs suitable for 2,000 tons of rails, at 7*l.* 19s. 6d. per ton, cast upon an iron core, and from second fusion. Messrs. Guest and Co.'s contract is to supply 1,000 tons of rails at the same price (12*l.* 2s. 6d.), and also deliverable in the river; warranted to be of the best quality, finished in the best manner, and free from every imperfection. The condition of the whole of these contracts is, that they shall be completed before the 1st of June, it being expected that the line will be opened as far as Ilford in the coming June or July.—*Railway Times.*

London and Croydon Railway.—The works on this line seems to be pushed on with as much rapidity as the inclement weather will permit. The viaduct of thirty-six arches, at the junction with the Greenwich Railway, is now completed, and appears to be of the most substantial character. The foundations, owing to the uncertain nature of the soil, are laid very deep, and secured on beds of concrete. The whole brickwork is built of the best hard grey stocks; the joints having been all raked out one inch deep, and pointed with Parker's cement. This gives a dark appearance, which, however, is well counterbalanced by the durableness of the structure. A large skew-bridge, of forty-eight feet span, is in the course of construction over Earl's Sewer. The works of this important bridge have been suspended during the frost, but will be immediately resumed whenever the weather is suitable. The skew-bridge over the Surrey Canal, consisting of three arches—the centre one being forty-eight feet span, and the two land arches twenty-four feet span—is also complete. The pilasters, string-courses, and coping, all present the most perfect workmanship; the same means for filling the joints having been resorted to here as in the viaduct before-named, and the rings of the arches being laid with the utmost care spirally in cements. The bridge by which the Dover turnpike road crosses the railway, has been long finished; and, notwithstanding the extreme flatness of the arch, a mode of construction which was necessary to avoid altering the level of the original road as much as possible, stands perfectly well. Near to this bridge, on the north side of the turnpike road, a space has been walled in to form a station for passengers and the locomotive engines. The earthwork, which in this contract is very heavy, is going on rapidly. It consists of the deep cutting on the south side of the Greenwich road, for the most part through the formations composing the upper strata of the London clay basin. The cutting is performed on two levels, the materials from the upper being thrown into a large spoil bank on the east of the line, while those of the lower are used in the formation of the embankment across the marshes, which has reached within about sixty yards of the bridge across the canal. The slopes have been neatly dressed in the cutting, and sodded, which not only improves their appearance, but imparts stability to them. The embankment is founded on an inclined rampart, formed of turf, running about five feet under it, and projecting two feet beyond, and having the upper part perpendicular to the external slope of the embankment. This method, which is new to us, will give stability to the embankment, as well as preserve its shape, by preventing those sloughs, or slipping at the foot of the materials, which may be observed on most large embankments. Two tanks are in the course of construction for the purpose of Kyanizing the timber, previous to its being laid down; and preparations have been made for laying the permanent way. Contracts for the remaining portion of the works have been taken, and operations will be commenced as soon as the state of the weather will permit. At the junction of the railway with the Surrey Canal, a piece of ground has been provided for the purpose of a depot for goods brought by the railway, to be forwarded by barges to different points on the banks of the Thames; and near to London Bridge, another considerable plot has been purchased for the purpose of constructing such a station as to afford ample accommodation to passengers, not only by the Croydon trains, but also for the ultimate traffic of the Brighton and Dover lines, both of which, in furtherance of the original view of the projectors of the Croydon Railway, merge from this trunk near Croydon, and proceed respectively through the south and south-east districts of England; thus giving to the Croydon Railway the extensive traffic of these districts in addition to that derived from its own locality. In a subsequent Report we shall advert more minutely to the mode pursued in effecting the earthwork on this line; and shall also notice the works at the Croydon end, which are in a state of great forwardness, being nearly completed up to the Jolly Sailors public-house, at Norwood.—*Idem.*

Newcastle-upon-Tyne, Edinburgh, and Glasgow Railway.—We understand that Mr. Richardson, the engineer, has arrived in Glasgow to make preparations for a survey of the line from Glasgow to Peebles. We would strongly urge all that are interested in obtaining cheap fuel to encourage this project, than which we know none that is more likely to be advantageous to the public. The utmost enthusiasm prevails throughout the whole line for the accomplishment of this great national undertaking; and we trust that the merchants and inhabitants of Glasgow are too much alive to their own interest to permit a scheme of a direct communication from this city to London to fall to the ground.—*Glasgow Paper.*

Edinburgh and Glasgow Railway.—The projected railway between Edinburgh and Glasgow, is the only one in Scotland which may be called national, as uniting the two principal cities, the two seas, and a population, including adjoining towns and counties, of nearly a million. This is a measure which is called for on national as well as local grounds.—*Aberdeen Herald.*

Lancaster and Glasgow Railway.—It will be recollected that at the recent railway meeting at Kendal, it was stated with much confidence that twenty miles would be gained between Lancaster and Carlisle, by the main trunk passing through that town, over the line up the vale of Lune, recommended by Mr. Locke. The saving of 280,000*l.*, the computed cost of this imaginary distance, it was said, would see them a good way through the expensive tunnel of two miles at Kentmere. This saving of 280,000*l.*, and of twenty miles, was, of course, an important consideration, and one could not help wondering what Mr. Locke had been about to suffer it to escape him. All surprise on this point is now at an end. The last number of the *Westmoreland Gazette* contains an important letter from John Hill, Esq. (we believe of Ormside) showing that there is not a balance of *one mile in favour of the Kendal* over Mr. Locke's line, by Kirkby Lonsdale. We shall wait with some interest to see this statement controverted (if possible) by the projectors of the Kentmere line.—*Lancaster Guardian.*

Enormous Train on the Liverpool and Manchester Railway. — Monday morning, a luggage train arrived from Manchester, consisting of 113 waggons of merchandise, drawn by five engines. Allowing ten yards to each engine, and fifteen to each waggon, the train must have extended upwards of 615 yards.—*Liverpool Standard.*

The Birmingham and Derby Junction Line is proceeding favourably. The contracts already let include, with a trifling exception, the whole of the

ine from Hampden-in-Arden, where it joins the Birmingham, to Burton-upon-Trent. The Directors confidently anticipate that the undertaking will be completed by Midsummer of next year.

The Leicester and Swannington Railway Company have declared a dividend payable on the 1st of March, as follows:—Share, 50*l.*; amount paid, 50*l.*; last price, 75*l.*; dividend, 8*l.* per cent. upon paid-up share. Share, 50*l.*; amount paid, 5*l.*; last price, 25*l.*; dividend, 17s. 6d. or 17½ per cent. upon amount paid-up; equal to 10¼ per cent. upon both.

Thames Haven Dock and Railway Company.—We are delighted to see that this work is likely to proceed; one of so much use ought not to have been so long neglected. A dock independent of its own use and that of the railway, is always an object of interest in an architectural point of view; and we trust the Thames Haven Dock will be as beautiful in art as it is beneficial as a work.

Sheffield and Rotherham Railway.—The works of this undertaking are rapidly approaching to completion, and in all probability the line will be opened for traffic about Midsummer. The engines are now being constructed by R. Stephenson and Co., and first-class carriages have been ordered from Manchester. Workmen are employed day and night.

North Midland Railway.—The long-continued frost has occasioned considerable hindrance in the masonry department of this undertaking. The excavators have continued their work, and are getting on fast, but so much remains to be done near the town of Chesterfield, that it is intended to carry on the work by night as well as by day. In order to accomplish this an application has been made to the gas company, for lamps to be placed on the line, and a meeting was held on Friday week to make the necessary and requisite arrangement. The directors have made another call of £10, making the whole £35 per share. Upwards of sixty miles of road out of the whole distance of seventy-two miles is now in course of being made. The Aire and Calder Navigation Company have thrown every possible obstacle in the way of the Railway Company, and in consequence a new line has been surveyed from Leeds to the Cinder-ovens, beyond Haigh Park; and the directors may possibly be driven to apply for a new act to empower them to take this line.

London and Birmingham Railway.—The portion of the line between Birmingham and Rugby may now be considered as finished, with the exception of the works at the stations, as a waggon traversed the whole length upon the rails a few days ago, saving only a few yards near Church Lawford, over which it had to be got along by horse power. The road in several places seems as if it had given, or was inclined, as indeed is always the case with roads recently ballasted; but every attention is being paid to its consolidation, and it is expected to be in very fair condition by the time the stations are completed. Most of the buildings at the Birmingham station are completed, and the remainder are proceeding with in as urgent a manner as circumstances will admit of.

Accident on the Manchester and Liverpool Railway.—On Wednesday, the 7th ultimo, the eleven o'clock first class train to Liverpool was on its way to that town, and had arrived within four miles of its destination, when a luggage train was perceived in advance with three lurries attached to it. The proper measures for slackening speed were taken, but singularly enough at that moment the axle-tree of the hindmost lurry broke, and all three immediately separated from the train to which they were attached and were left behind. The consequence was that the engineer of the train following, which was still going at a quick pace, had not time to stop ere the engine bore down upon them, throwing the lurry off the rails, and scattering them in pieces across the line. The shock also threw the advancing engine off the line, and the train would have been left without the means of proceeding to its destination but that the engineer of the luggage train, who was but a little in advance, witnessing the shock, brought back his engine and took the train with very little delay forward. None of the passengers were injured, though the concussion created much alarm.

Manchester and Leeds Railway.—The works of this railway are now in active progress; contracts have already been entered into with responsible parties for about twenty-five miles of the line. The important works at the Summit Tunnel have also been let to respectable and experienced contractors, making altogether more than half of the line at present under contract. The works have been urged forward with all practicable expedition, and extensive preparations have been made for the most vigorous exertions in the spring of this year. The shareholders may therefore look forward to the completion of the entire line with all possible dispatch. The public, also, appear duly to appreciate the present promising aspect of affairs, the shares having risen in value from £3 to £4 each within the last month.

North Union Railway.—Within the last few weeks considerable progress has been made in the formation of the North Union Railway, between Preston and Wigan. The operations on the bridge across the Ribble have been very actively carried forward.—*Derbyshire Courier.*

Disaster at the Preston Railway Bridge.—Although the thaw which commenced in the latter part of January was mild, the masses of ice began to break on Monday morning; and about noon, the mass between Walton Bridge and the Tram-road Bridge, thickened by the sheets which escaped at intervals from the rapids up the river, broke from its hold with a loud crash, and floated till it reached the Tram-road Bridge, where, being intercepted, it again found a lodgment, and was stayed more than two hours. When this period had elapsed, the loud and repeated breakings gave signal of another general movement. The principal damage was done to the Railway-service Bridge, or the temporary line on which the materials for the erection of the bridge are conveyed; upwards of 100 feet are entirely carried away. A considerable portion of time will be sacrificed, but every precaution has been taken to meet any future emergency.—*Preston Chronicle.*

Railway Bills for this District.—The following notices of intended applications for Bills during the present session of Parliament have been given, connected with works in this part of the kingdom—namely, *The Clarence and Hartlepool Union Railway and Asylum Harbour*—to make deviations and alterations, to form a branch, a canal, and dock. *Great North of England Railway*—to alter, amend, and enlarge the powers of their former acts. *Maryport and Carlisle Railway*—to amend and alter former acts. *Morpeth and Tyne Railway*—for new line. *Newcastle-upon-Tyne and Carlisle Railway*—to raise a further sum of money. *Gateshead and Newcastle-upon-Tyne Railway*—new line from Gateshead to Newcastle. *Newcastle-upon-Tyne and North Shields Railway*—to make a branch from Shields to Prior's Haven, Tynemouth. *West Durham Railway*—new line from Brancepeth, to join the Byer's Green branch of the Clarence Railway. *Whitehaven, Workington, and Maryport Railway*—new line.—*Tyne Mercury.*

Fire from a Railway Engine.—On Wednesday, the 24th ult., such was the violence of the wind, that as the locomotive engine was being used to remove earth on an enbankment of the London and Birmingham Railway, about midway between Stony Stratford and Northampton, flakes of fire were carried a distance of forty-five yards from the railway over a farm house on the property of the Duke of Grafton, and being deposited in the rick-yard, occasioned the destruction of corn stacks and other produce to the amount of 700*l.*

The Grand Junction Railway Company have commenced the carriage of merchandise. In a circular just issued, the Company observe, that their present means of conveyance being limited, the rates are calculated accordingly. The present rates are as follow:—"*First Class.*—All metals in bars, rods, or ingots—nails, chains, rivets, and such goods—sugar, salt provisions, and the like—2s. per cwt. *Second Class.*—Hardware in packages—glass in boxes—heavy bale goods and boxes of linen—fruit, groceries, oils, &c.—wines and spirits—2s. 6d. per cwt. *Third Class.*—Tea—furniture, light bales and trusses—fish—glass in casks—fenders, tubes, and the like loose packages—3s. per cwt."

America.—The Wilmington and Raleigh Rail Road, when completed, will be 170 miles in length, of which about 30 miles are completely finished, and about 60 in a state of great forwardness. This road is in a straight line from Wilmington to the junction of the Norfolk and Petersburgh Rail Roads. It is expected the whole will be finished in about 18 months. At present a line of cars run over the road now finished, which enables us to reach Charleston in a fraction over three days. This road does not touch Raleigh.—*New York Express.*

Western Railway between England and Scotland.—We hope very soon to have before us a published statement of the progress that has been made in the matter of the survey of the Railway line between England and Scotland, by the way of Annandale. The survey, we believe, is now completed; and from Mr. Locke's report, in connexion with some additional levels taken by Messrs. M'Callum and Dundas, who assisted him, we understand that the formidable heights above Moffat can be got over without even a single stationary engine. What the Committee intend next to do we cannot yet say; but we presume they will watch the Railway Share Market, and if, as may be expected, we shall by-and-by have a new flush of commercial enterprise after the late depression, why then they may find that market again brisker than ever, and so, bringing their speculation forward, may meet a ready demand. Then, also, is the moment to lay their schemes before Government, and get national aid for the vast undertaking, when men's minds are on the alert with regard to it. We confess we are every day becoming more hopeful that it will ultimately be carried into effect, as we cannot suppose this bold and vigorous age will rest satisfied till it is done. We are speaking, be it remarked, not of the Annandale line precisely, but of some one Western line—for we believe we shall hear little of any other now but a Western line, to join Lancashire and Lanarkshire, the greatest seats in the kingdom for manufacturing industry. Meanwhile let us ask what the friends of the Nithsdale line are about? Are their funds made up? Are they ready for their survey? The thing seemed entered upon in several quarters in a spirit and feeling of very unnecessary rivalship with the Annandale line. There is no occasion for any such narrow jealousy. Let the thing be calmly gone about, and in the proper time let it also come before Government. A more thorough knowledge of circumstances connected with the great national undertaking of a Western line between the two kingdoms will thus be brought before the State; and the circumstance that two competing lines are submitted to its consideration, will rather corroborate the importance of the general scheme, by showing that men's minds in various quarters are made up as to its feasibility, than render Government reluctant from any difficulty of conflicting claims. For we are not for a moment to suppose that any subordinate advantage, by the way to this town or to that, will be allowed to sway and turn aside the one broad general calculation as to which line shall yield the greatest amount of benefit in a national point of view; and if Government aid is to be granted, of course Government will decide on the line to be adopted.—*Dumfriesshire Herald.*

Bristol and Exeter Railway.—In a recent interview of a deputation from the directors of the "Bristol and Exeter" Railway Company, the Lords of the Admiralty fully admitted that a point, either at Brean Down or Black Rock, on the coast of Somersetshire, on the line of that railway, will be the great national shipping and landing-place for communication between the Atlantic and the south of Ireland with the metropolis. We are not surprised at this admission on the part of such high authorities, as the fact is, letters and passengers will, we understand, by this route arrive in London, *via* the "Bristol and Exeter," and the "Great Western" Railways, in *four hours* from the coast, being as quickly in favourable tides as they would arrive in Bristol; and in tides which would be missed at Kingroad, will effect a saving in time

of at least eight hours, as compared with the route through the Avon. As compared with the route *via* Milford, the saving of time will be at least *one-half* that now occupied.—*Bristol Journal.*

The Berwick and Kelso Railway.—The company for this undertaking, which for years has exhibited itself as a chrysalis among the enterprising pursuits of our country, has, after various attempts having been made to thaw it into activity, been broken up—a proper termination to what seemed in capable of being inflated with vitality. We are far from regarding, however, the scheme of connecting the western country with this town, by means of a railway, one iota more unpromising from the death of this company. Every year, in our opinion, exhibits fresh inducements to such an undertaking, while no detraction from the original impetus has taken place. No one, we think, acquainted with the rapid advances made and still making in the manufacturing districts to which this port is the natural outlet, but must be led to see the demand for a railway. The determination which seems to exist in Newcastle, to push forward a railway from that town to Edinburgh, should have had some influence in staying this recent act of the Berwick and Kelso Company, as, in our opinion, whatever line is adopted for continuing the Great North of England Railway—whether it is carried through our neighbourhood, or through the midland country—in either case we think a railway between this and the west country is seriously desiderated.—*Berwick Advertiser.*

Glasgow and Ayrshire Railway.—We understand that vigorous preparations are making by the directors to have the works on this important line of rail way commenced in spring. Mr. Locke, the celebrated engineer of the Grand Junction Railway, has been appointed to execute the line between Glasgow and Paisley, held jointly with the Greenock Company; and Mr. Miller, of Grainger and Miller, has been named to execute the other portions of the railway.

ENGINEERING WORKS.

New Bridge over the Ouse at Selby.—The contractor has commenced driving the piles for the new bridge at Selby, for the Hull and Selby Railway Company. The bridge is on a new plan, and is peculiarly calculated to answer its purposes. The present bridge is what is termed a swivel bridge, but the new one will be a leaf bridge, opening in the centre, and drawing up one half from each end to admit vessels to pass. There will be a windlass at each approach, which may be easily worked, with the aid of balances, by two men, and thus the bridge will be raised in less than half a minute, and closed in the same time at most. The company have an active and intelligent resident engineer at Selby, who devotes his entire time to the superintendence of the workmen, and when complete, we have no doubt the Hull and Selby railway bridge (the first of the kind, we believe) will serve as a pattern for many others.

Mersey and Irwell Junction with the Rochdale Canal.—We understand that this work is proceeding most rapidly, that the contractor, Mr. Mackenzie, expects that an opening from one end of the tunnel to the other will be made in a few weeks; and that the canal will be completed by the latter end of September. It is astonishing that an undertaking such as this can be carried across a town like Manchester in so short a time (for it was only commenced in August last), with comparatively so little public inconvenience.—*Manchester Courier.*

NEW CHURCHES.

Nottingham.—A new church is in course of erection at Sneinton, near Nottingham, from the designs and under the superintendence of those eminent Gothic architects, Rickman and Hussey, of Birmingham. The plan is a Latin cross, with a tower (27 feet square externally) at the intersection. Interior dimensions 120 feet 3 inches from east to west, by 28 feet 3 inches wide, and the transepts 23 feet by 28 each. Gallery at the west end 28 feet 3 in. by 25; the whole affording accommodation for 1,250, including children. The interior is remarkably plain, owing to the timbers of the roof being in view, entirely devoid of ornament. The pulpit and reading desk are placed on each side of the chancel arch, the floor of the chancel being elevated two steps above the body of the church; the exterior is cased with stone from Coxbench quarry, near Derby, and presents an unique elevation, in the early English style, the chief feature being a wheel window of noble dimensions in the gable of the north transept. The total cost of erection, including architect's commission, is 4,000*l.*; but it is contemplated (if a sufficient sum of money be obtained during the course of erection) to raise the tower 12 feet (its present height being only 78 feet 6 inches), and place an elegant pinnacle on each of the angular buttresses; this, together with the insertion of tracery in the principals of the roof, will render this edifice the best specimen of architectural skill, combined with rigid economy, of which this neighbourhood can boast. H. G.

New Church at Stroud.—The contracts for the new church at Stroud are allotted, by her Majesty's Commissioners, to Messrs. Hawkins and Co., builders, of Bristol. The plans are designed by Mr. Foster, architect, of Bristol, in the early English style of the thirteenth century. The church is to contain 1,000 sittings; and it may now be calculated that the foundation stone will be laid early in March.

Stafford.—A new church is now building at Stafford, from a design by G. E. Hamilton, Esq. It will be of brick, ornamented with stone, in the form of a cross; with nave and transepts. It is to have a Norman tower, lance windows, and buttresses; and is intended to accommodate 600 persons, 300 of which will be free.

Bury.—A new Roman Catholic church was opened at Bury. It is a very handsome piece of architecture. The interior dimensions are 87 feet by 41 feet 9, and 35 feet 11 high.

PUBLIC BUILDINGS AND IMPROVEMENTS.

Surrey Lunatic Asylum is to be erected in course of the ensuing summer. The county magistrates have purchased a considerable portion of the Springfield Lodge Estate, situate near Tooting, the property of H. Perkins, Esq. A limited number of architects will be selected for sending in competition drawings.

Woolwich Dock Yard.—A very extensive engineer's workshop and foundry is about to be built near the new basin.

A monument has been recently erected in Lutterworth church to the memory of John Wiclif, the first translator of the Bible. It is the work of Mr. Westmacott, jun.

City Improvements.—The following is the substance of a Report made at the last Court of Common Council on the subject of the project of the new street from Farringdon Street to the northern road:—"The committee directed the Remembrancer to give the necessary notices of an application to Parliament for the promotion of the proposed new street northward as far as West-street. On the 24th day of November last they were attended by a deputation of magistrates of the county of Middlesex, and commissioners of sewers for the Holborn and Finsbury division, who stated their desire that in the application to Parliament power should be taken to continue the new street to Peter-street, near Cow-cross; and that although the commissioners had no funds applicable to the improvements, they were in hopes, that if power was given to take the property, funds might be found for that purpose; and the committee accordingly directed the Remembrancer to give the necessary returns to the owners and occupiers of property as far as Peter-street. Having taken into their consideration the best means of raising a sum of money for the continuation of Farringdon-street to West-street they were of opinion that a sum of sixty thousand pounds might be raised on the produce of the tolls payable at the several bars of the City, which they considered would be amply sufficient for the purposes required, and that the application of those tolls to the purposes of public improvements would in a great degree obviate the objections made by some persons to the payment of them, and they directed a petition to be prepared for an application to Parliament for the purposes aforesaid."

Rebuilding of the Royal Exchange.—At a meeting of the Royal Exchange Committee held on the 20th ult. at Guildhall, with closed doors, Richard Lambert Jones, Esq., in the chair, some business was transacted. Mr. Jones, as chairman of the deputation to the Chancellor of the Exchequer on the subject of the grant of a sum of money to defray the expense of building a new Exchange, informed the meeting that the deputation had been received with the utmost cordiality by the right hon. gentleman, who expressed an opinion that the citizens ought to avail themselves of the opportunity afforded by the late calamity to raise an edifice combining utility and splendour in a high degree; but observed, that the government could not aid them without the sanction of parliament; and that it would be therefore necessary to refer the matter to the Select Committee of the House of Commons on metropolitan improvements. The committee then proceeded to consider a communication from Mr. George Smith, the surveyor of the Mercer's Company, to the Lord Mayor, stating that the Royal Exchange tower was not in a state of security, and that it would be necessary to take the building down. The apprehension of insecurity, it appeared, arose from the injury done to the stone work by the frost after it had been exposed to the fire, and by the heavy rains subsequently; and it was the decided opinion of the surveyor that the tower should be taken down. Upon a former occasion a very strong opinion having been entertained by some of the members of the committee, that part of the old building should be retained, and that the future work should be rather a restoration of the old Exchange than the construction of a new one, Mr. Montague, the city surveyor, was examined on the subject, and he gave it as his most decided opinion that no part of the walls ought to be retained. The chairman said it would be a very extraordinary sort of judgment that could determine to keep walls 150 years old, when it was admitted that the tower, whose walls were quite new, must be levelled, and he thought very little of the understanding of any person who suggested so unreasonable a proposition. Mr. Smith admitted that Mr. Montague's opinion was correct, and Mr. Montague was convinced that for economical as well as other reasons, it would be necessary to take down every part of the building. It was then determined that the whole of the ruins should be levelled and disposed of as soon as possible by public auction, and that the entire site of the Royal Exchange should be cleared to the pavement, and we understand that immediate steps will be taken to accomplish that object. A gradual sale will take place, and the scaffolding at present erected will be allowed to be used for the removal, although raised, we believe, for a very different purpose.

Anti-Combustion Muslin.—We have now before us a piece of muslin, which, on being put into the flame of a candle, or thrown into the fire, merely carbonises, without flaming; so that any woman dressed in materials so prepared, cannot be burnt by any of those accidents by which the young and the aged too often suffer the most painful deaths. The finest colours are not affected by the process. It is equally applicable to every substance, from the canvass of a ship-of-war to the finest lace—for the curtains of beds, the furniture of rooms, the coverings of sofas, and all those materials which often cause conflagration. It also prevents the attacks of mildew. Papers subjected to great heat only carbonise, and leave the writing or the numbers and value of the bank-notes legible. The general utility of this discovery will command attention. We understand that a foreign government has commanded its use, and that a company is forming for its immediate introduction. The process, like all useful things, is simple in the extreme, and about as expensive as starching a dress.—*Literary Gazette.*

POTOMAC ACQUEDUCT.

B Ditto ten inches diameter to inner row.
C Sheet piling to outer row, six inches thick.
D Ditto to inner row.
E Wales, or outer stringers, one foot square.
F Ditto, or inner stringers.
G Four sets of shores across the interior of the coffer-dam, on a level with the bottom of the river is a double course of stringers and shores.
H Wales, or stringers, twelve by six inches, to guide sheet piling, called in America the lower and upper *sash*.
I Cross pieces and braces.
J Four main or *thorough* ties, connected at each end in pairs with cross-ties.
K Clay puddling.
L Mud or silt to be excavated.
M Rock bed of the river.
N Silt or mud.
O Bottom of the river; natural surface of mud.
P Surface of the river at ordinary spring tide.

MACHINERY.

Q Two floating steam-engines, of twenty-horse power each.
R Floating stages.
S Boilers.
T Gear for working dredging-machine and raising skids.
U Gear for working pumps.
V Two pumps, worked by a rope passing over sheaves, eighteen inches diameter, attached to a drum four feet in diameter.
W Dredging machine.
X Railway for dredging machine to run on.
Y Windlass, rope, and buckets, for raising the mud excavated.
Z Lever to put the windlass in and out of gear.
a wooden *scows* (flat-bottomed boats, or barges).

REFERENCE TO FIG. 3, 4, & 5.

a a, two sheet piles, thirty-seven feet long, thirteen by six inches, connected by two pieces of timber at the top *b*, and the same at the bottom *c*, called the upper and lower sash, or guides.

CAPTAIN TURNBULL'S REPORT

On the Survey and Construction of the Potomac Aqueduct, by Order of the House of Representatives.

POTOMAC AQUEDUCT, *Jan.* 1*st*, 1836.

Lieut.-Col. Abert, Top. Bureau.

SIR,—I have the honour to report, that immediately on the receipt of your order of the 20th of August, 1832, concerning the Potomac Aqueduct, I communicated the same to T. F. Mason, Esq., the President of the Alexandria Canal Company; and I soon after made the necessary examinations to enable me to determine the proper position of, the extent, character, and cost of the work. By these surveys were ascertained the depth of the river, from the plane of high water to the muddy bottom, and the depth and nature of the deposit beneath the river to the solid rock which underlies it; the direction and probable velocities of the current, and the length and direction of the aqueduct, and of its abutments and embankments; the quantity of excavation necessary to carry the masonry to a solid foundation, and the strength which should be given to the structure, to enable it to resist the pressure of the ice and other floating matter which is carried down by the freshets of the river.

The site of the aqueduct had been already fixed, in 1829, by Messrs. Wright and Roberts, engineers of the Chesapeake and Ohio Canal Company, as may be seen by their report of that year. Among the drawings which accompany their report, there is one which would seem to be a profile of the river, and to exhibit the depth of water and the mud beneath (see fig. 2); but in their report they state, that after the first sounding, which they made fifty feet from the shore, the iron rod which they had prepared themselves with for penetrating the mud was lost, and they think it safe to estimate the depth of mud from three to five feet for the remainder of the distance (1,530 feet), an estimate which it will be seen hereafter is very far from the truth.

My survey of the river shows a line shorter than theirs, and at the same time exactly at right angles to the thread of the stream, and nearly in continuation of one of the streets of Georgetown.

Influenced by the decided superiority of this line over that selected by Messrs. Wright and Roberts, and coinciding in this opinion with Mr. Fairfax, the engineer of the Alexandria Canal Company, with whom I at that period acted, we applied to the mayor of Georgetown for the consent of that corporation to use that street as the northern abutment of the aqueduct; and we suggested to him the idea, that it might be of advantage to the town to unite with the Alexandrians in constructing a roadway upon the piers of the aqueduct. This suggestion met with the decided approbation of the mayor, and he referred the subject to the councils, each branch of which appointed a committee to confer with the engineers; but the subject was not acted upon by these gentlemen. Six or eight months thereafter, however, when it became necessary to lay off the work for the contractors, they were induced, by the earnest solicitation of a gentleman of Georgetown, to meet the engineers on the ground. They were then unanimous in consenting to our using the street next west of the one designated by us; but not having power to act definitively, the matter was again referred to the councils, which took no further steps in the matter; and we were therefore necessitated to fix the abutment upon the site designated by Messrs. Wright and Roberts.

I narrate these facts, that professional men, commenting upon the position of the axis of the aqueduct, which is oblique to the stream, may be informed that neither Mr. Fairfax nor myself had any agency whatever in placing it where it is; but that, on the contrary, we were compelled, by circumstances beyond our control, to adopt it.

BORINGS OF THE RIVER.

The borings for the foundations were conducted after the method by which the main or framing piles of the coffer-dam for the tide-lock at the western termination of the Caledonia Canal were fixed to the rock, only that we used a square box instead of a cylindrical one; that is to say, the box was formed of three-inch heart pine plank, thirty-six feet long, eight inches in the clear inside, well jointed and banded with flat iron bars, the lower end of the box was shod with flat iron shoes, edged with steel, and fitted on the end of each plank, to prevent its being damaged by stones while driven to the rock; it was then driven in the ordinary manner of driving a pile, as far as it could be driven without crushing. It was then emptied by means of an auger, made in the form of a quadrant of a circle, of the same diameter as the inside of the box; the circular side, and one of the straight sides of this quadrant, for eighteen inches of height, were made close, of thin rolled iron, rivetted to the ribs, which were fastened to the corners of the quadrant; from this proceeded an upright shaft, the other straight side being open to the bottom of it. Four flat teeth, each two and a half inches long, were fixed with an inclination downwards, so that when the auger turned, these teeth loosened the sand, and prepared it to enter easily into the body of the auger. To keep it steady while turning, there was fastened to the lower side of that corner of the quadrant, which is the centre of the circle, a pivot six inches long, which passed into the sand, and served as a centre for the auger to turn upon. Immediately above this pivot stood the upright shafts, made of inch square bars of iron, capable of being joined by male and female screws, five and ten feet long, to any required length: upon this two cross handles were placed to turn it with. A scaffold was erected by spiking strong pieces of timber to the deck of the pile-driver scow; their ends extending beyond the planes, planks were laid across these for a platform, upon which four men stood to turn the auger. From four to six turns, according to the nature of the stratum through which it had to pass, filled it. It was lifted above the top of the box by a purchase acting from the top of the pile-driver, and the sand was then cleaned out with a small shovel, by a man standing upon the scaffold. At all the borings but one, where a stratum of coarse gravel two feet above the rock occurred, the box was driven to within a few inches of the rock, and in all cases when the box was emptied, a sounding-rod of iron, one inch diameter, was dropped into it, which rebounding several feet, proved that the solid rock had been reached.

At the point where the gravel occurred, about three fourths of the way across the river, reckoning from the north side, the first attempt to reach the rock was ineffectual, the gravel caving in under the foot of the box as the auger was withdrawn; and as the box was required for other borings, it was thought unsafe to risk driving it through the gravel until the others were completed; but when they were, the box was brought back to the gravel-bank, and driven with great force, until it began to spring or burst, although it had not yet entirely penetrated the gravel: it was, however, emptied to the foot, and a sounding-rod of iron was forced through the remainder of the gravel to the rock.

The box was always drawn by the crank of the pile-driver, with the assistance of a double and single purchase blocks. The number of borings were so multiplied as to prove the existence of rock under the entire bed of the river, at an average depth of twenty-eight feet (instead of twenty-five feet, as estimated by Messrs. Wright and Roberts) below the surface of ordinary high-water mark.

With the data thus obtained, a profile of the river was constructed, exhibiting the depth of water and mud to the rock.

The subject which next claimed the attention of the engineers was a plan for the purposed work. Having no instructions on this point, we were left entirely to the guidance of our own judgment, and to the influence of the

facts which my survey and examinations of the site of the work had brought to view; and these were such as to induce us to give to the plan a character of the utmost stability as it respected the foundations, and one of equal durability to the superstructure.

DESIGN.

It was to consist of twelve arches of stone, supported by eleven piers and two abutments, the arches to be one hundred feet span and twenty-five feet rise: the soffits to be curves of eleven centres, three abutment piers, being every third pier, to be each twenty one feet thick at the springing of the arch, and eight piers of support, each to be twelve feet thick at the springing; the masonry of the land abutments to be twenty-one feet thick.

This plan was approved of by the president and directors, with the exception of the superstructure, the cost of which being beyond the limited means of the company, was left for after consideration. The plan was further altered by rejecting the abutment piers, but eventually these were restored, on the recommendation of the engineers. A causeway of earth, 350 feet in length, was substituted for three of the arches at the southern extremity of the work.

The adoption of the causeway made a change in the arrangement of the piers necessary, and it was then decided that the aqueduct should consist of eight piers, 105 feet apart at high-water mark; two of them to be abutment piers, each twenty-one feet thick; and six of them piers of support, to be each twelve feet thick at high-water mark. The southern abutment to be twenty one feet thick, with circular wing walls thirteen feet average thickness at the base; sixty six feet in length on each side, to connect with the slope walls of the causeway.

The northern abutment, which is to be built by the Chesapeake and Ohio Canal Company, is not yet decided upon. Each of the piers to have an ice breaker upon the up stream end, in form of an oblique cone, sloping forty five degrees, extending five feet below, and ten feet above, high water mark, made of cut granite. The down stream ends to be circular, and to have a batter, or slope, the same as the sides, one inch to the foot.

Upon this plan the work has been commenced, and so far progressed.

TENDERS.

On the 29th of January, 1833, by the order of the board of directors, the engineer advertised for proposals to build the aqueduct upon the plan above described. Several offers were received, varying from 99,092·13 dollars to 217,909·63 dollars; among the number was one from Messrs. Martineau and Stewart, one of which firm (Dr. Martineau) afterwards submitted a proposition for the coffer-dams alone, proposing to build them upon a plan which he claimed as being original, and eulogised it for its supposed economy, and for the facility with which it might be constructed; this plan was submitted to the investigation of the engineers, who, after a careful examination of the principle, reported against it, under the persuasion that it was incapable of being made water-tight, and insufficient to resist the pressure of so great a column of water as must have necessarily pressed upon it. At the engineers' solicitation, however, Col. Kearney was requested by the board of directors to unite with them in their investigation of the plan. After a careful examination, he agreed with the engineers in the opinion of its total insufficiency.

During the winter and spring of 1833, the engineers were occupied in analyzing the various bids that were received, and which were from time to time reported to the board.

On the 8th of June, 1833, Messrs. Martineau and Stewart submitted a modification of their former bid, and the board of directors were influenced, by the professional reputation of Dr. Martineau, and the most unexceptionable assurances of the integrity and pecuniary ability of Mr. Stewart, to accept it; and accordingly, on the 29th of June, a contract was signed by them, by which they undertook to construct the piers and southern abutment, agreeably to the specifications of, and under the direction of the company's engineers; but the contract gave to the contractors a specific sum for each coffer dam, whereby the engineers were necessarily precluded from interfering with their plan, and the one which had been reported against by them, was then attempted to be built by the contractors.

CIRCULAR COFFER DAM.

It was formed of two circular rims, eighty feet in diameter, and supported one above the other by posts; the lower rim rested upon the mud, the other at the surface of the water; each rim was formed of pine timber 12 by 14 inches, in segments of ten feet in length, connected together simply by iron dogs; in the centre of each segment a rabbit was made, through which a pile, with a two inch plank spiked upon the back, was driven to serve as a guide pile; this divided the circumference into spaces or panels of ten feet, which were afterwards filled with piles of white pine, eleven inches in thickness, planed on the joints, firmly driven into the mud, but not to the rock. It was merely a single row of piles, without puddling to prevent leaks, and without shores to resist the pressure of surrounding water and mud.

The contractors evinced neither energy nor willingness to press the work forward, and it was not until the 2nd of September, when they sub-contracted the work, that it may be said to have been commenced, although some materials had been delivered previously. On the 26th of September the circular frame of the dam was towed to its position on the axis of the aqueduct, and on the 2nd of October it was weighted down to its place, bad weather having prevented its being done before that time; the driving of the piles around it progressed but slowly, there being but one pile driver employed; and it was not completed until the 16th of November.

A steam-engine of twenty horse power was placed upon a platform on piles, outside of the dam, on the down-stream side. December 15th, the engine being in readiness, it was put in operation at low-water, working eight pumps, capable of raising five hundred cubic feet of water per minute. At the expiration of one hour, the water in the dam had risen 8½ inches, equal to the rise of the tide outside, whereby was plainly shown the impossibility of emptying it. Several other attempts were made to empty the dam, but with no better success than the first, when the winter set in, and put a stop to further operations.

By the breaking up of the first ice, with which came also a freshet, about the 21st of December, the dam was crushed; and the contractors evincing no greater disposition to secure their property than they had shown to advance the work, the board of directors, on the 4th of January, 1834, formally declared the contract abandoned, and directed their engineers to take possession of the contractors' property, held in trust for advances made to them. They also directed the engineers to procure the machinery, &c., necessary for a vigorous prosecution of the work the ensuing spring.

In compliance with these directions, two steam engines, of twenty horse power each, were contracted for, as were also the vessels or scows necessary to receive the engines. Timber, stone, and cement, were advertised for, and the building of three pile drivers was immediately commenced, two of them calculated to be worked by horses, for driving the heavy oak piles; and the third, a light one, for driving the short piles, to be worked by a tread wheel; a fourth (received from the contractors), worked in the ordinary way, by a crank, was repaired. A machine for excavating the interior of the coffer-dams was also ordered to be constructed by H. Smith, Esq., of Alexandria.

Sixteen pumps were constructed, each of them formed of eight white pine staves, three inches in thickness, and thirty-eight feet long, and bounded together with iron; they were eighteen inches in the clear inside, at the upper end, and tapered three inches in the whole length, to facilitate the driving of the bands. At first they were left octagonal on the outside, but it being found very difficult to fit the bands, and make tight joints, they were afterwards rounded on the outside, and circular hoops substituted for the bands, which had been octagonal, as well as the pumps. Narrow slips of cotton cloth, coated with white lead, were laid in the joints between the staves; the hoops eighteen inches apart, well driven, made these perfectly tight.

The lower box, or valve of the pumps, was formed of a cast-iron plate, bevelled on its edges to fit opposite angles of the octagonal trunk; on each side of it was a leaf composed of two pieces of plate-iron, between which was screwed a stout piece of leather, trimmed to fit the sides of the octagon, these two leaves were screwed to the cast iron plate, the leather being the joint or hinge. In the top of the cast-iron plate, a ring was formed for the purpose of hoisting out the valve; in the lower part of the plate was another ring, or hole, through which a rope was passed to draw it firmly into its place in the pump, and, when there, an iron screw bolt, one inch in diameter, was passed through the pump at right angles to the valve; and, underneath it, to prevent its being forced further down by the column of water. The upper bucket was an inverted cone, twenty-seven inches in length, and of the same diameter as the pump, made of two thicknesses of short leather, well sewed together, through which was passed an iron rod, one inch thick and 7·4 feet long, projecting below the vertex of the cone 26 inches, upon which were placed leaden weights, secured by a screw nut on the end. The rim of the cone was divided into spaces corresponding with the octagonal sides of the pump, to which were secured rings, by means of straps of iron, one foot in length, passing in and outside, and rivetted through the leather by flat headed rivets. To these rings were hooked chains, which were suspended from the iron rod just below the eye or ring, at the top; through the ring at top was hooked a seven-inch rope of white hemp, which passed over a cast iron grooved sheave, three feet in diameter, placed immediately above the pump, and thence under another sheave of the same diameter, to the steam-engine, which worked it.

On the first opening of spring, March 1, 1834, preparations were made for removing the circular coffer-dam, built by the contractors, Martineau and Stewart. On the 4th of March the first pile was drawn, and on the 26th the whole of that dam was removed.

The piles were drawn by means of derricks or shears, erected on scows, by a winch, bolted to the deck of the scow, and by double and single purchase blocks. Two of these derricks were employed, and sometimes it was necessary to attach both of them to one pile; sometimes a lever was used to draw the piles; ordinarily, however, the single winch, worked by six men, was sufficient.

Experience in founding upon rock, at so great a depth, is very limited in this country, there being but one example, viz., the bridge over the Schuylkill, at Philadelphia, and that not strictly a fair example, the rock not having been entirely laid bare. I take the liberty of extracting from the report of the building committee, some notice of the difficulties which beset that work.

"A well intended, but mistaken endeavour to excavate all the silt and mud out of the dam, was arrested in time to save the whole from ruin.

"The balance of pressure of the exterior head of water, was perceived to be on the point of being destroyed; and the attempt of a total removal of the whole contents of the dam, was fortunately discontinued. The president, who, by constant attention, was minutely acquainted with the principles and construction, and of course the fort and foible of the dam, became uneasy; and intimated to the mason that the prosecution of the attempt of

the total excavation, was dangerous in the extreme; the mason was convinced that the opinion was correct, and the superintendent declared he had long been apprehensive of the consequences.

"At length the critical period arrived, when it appeared highly probable that another day's work would have defeated the whole enterprise. It was known that nothing but actual perception of the consequences would bring conviction, which all reasoning (resisted by the strong desire to reach the rock) had failed to produce. Several of the stoutest labourers were set to work, with a view to dig a pit to the rock, which was not more than three or four feet from the then surface; they had not pierced the mud above one half its thickness, before a column of water, copious and alarming, suddenly gushed up; this produced an immediate conviction of the unjustifiable hazard of any farther attempt to bare the rock; and the factitious foundation being without further hesitation agreed to, was forthwith commenced."

No descriptive memoir of drawings of this work ever having been published, nor of the London bridge, the deepest foundation perhaps in Europe, the engineers, therefore, had to proceed with the greatest caution; they were aware of the very exposed situation of the work, and impressed with the absolute necessity of founding it directly upon the rock, the difficulties and dangers of the attempt, although they were foreseen, were deemed subordinate to the great object of stability; and in this view, they were promptly sustained by the president and directors of the company.

The coffer-dams for the construction of the bridges of Neuilly and Orleans, designed by the distinguished Peronnet, were selected as models; but as these dams were for foundations of comparatively little depth, or such as were supported by piles, and where the water only was required to be emptied, alterations were found to be necessary to make them suitable to the great depth to be reached in this case.

COFFER-DAM, NO. 2 PIER.

See Fig. 1 and 2.

The coffer-dam first undertaken was to occupy the position of the pier No. 2, reckoning from the Virginia shore, and the next north of the one intended to have been built in the circular dam of Messrs. Martineau and Stewart, in a depth of eighteen feet water, and seventeen feet four inches of mud.

The figure of the dam - a parallelogram eighty-two feet long, by twenty-seven feet wide inside. The first pile was driven upon the axis of the aqueduct, which had been carefully established, and its distance from the southern shore carefully measured by means of a straight graduated float, on the 16th of May.

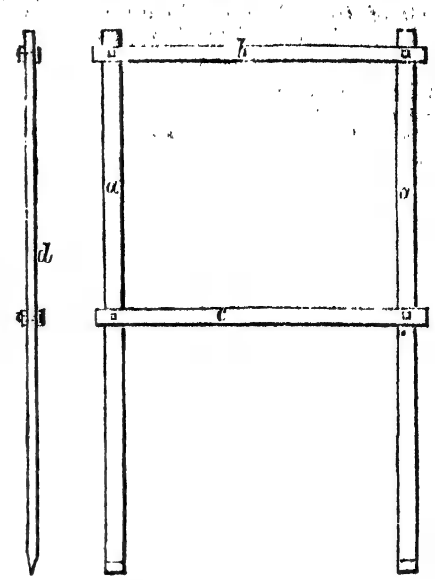
The inner row of piles were of white oak, forty feet long, sixteen inches diameter at the larger end, shod with iron, pointed with steel, weighing twenty-five pounds; they were placed four feet apart, from centre to centre, of each pile, and driven to the rock with a ram weighing 1,700 lbs. These piles were connected on the inside by a pine stringer one foot square, bolted with iron screw-bolts passed through each of the oak piles; the corners were secured by a strong iron strap with a gib and key.

The outer row of piles, fifteen feet from and parallel with the inner row, was also of oak, thirty-six feet long and sixteen inches diameter at the larger end; they were placed four feet apart from centre to centre, and pointed, but not shod nor driven to the rock.

These were likewise connected by a pine stringer on the outside, one foot square, screw bolted to each oak pile; the up stream angles of the dam were cut off, so that the outer row of piles formed a hexagon, the angles were secured by the stringers overlapping each other three feet, and halved on to each other.

These piles were driven without bands on the butt ends, as customary; a method recommended by G. Whistler, Esq., formerly of the army, was adopted, viz., the butt ends were made concave, three-quarters to one inch deep, with an adze, and covered with a thin piece of sheet-iron, simply laid on, by which means a pile, it is believed, may be driven to any depth without injury.

Upon the two rows of oak piles, or rather upon the stringers, a scaffold was erected, upon which the pile drivers were placed for driving the sheet piles (pile plank), which were of the best North Carolina heart pine; those for the inner row were forty feet long, and six inches thick; they were driven in panels (montants) of sixteen feet, formed by bolting (the bolts having room to play) two pieces or guides, eighteen feet long, and twelve by six inches, to two pile planks, eight feet from the foot, the pile plank between the string pieces or guides (see figures 3, 4, and 5); the piles were then suspended in the planes of the pile drivers, placed at the proper distance apart, and lowered in their places, the guide pieces sliding against the oak piles; it was then driven by slight blows of two pile drivers, the ram of one resting upon the pile, while the other made a blow, and so alternately, until the cross or guide pieces rested upon the mud (even moderately long blows were found either to shatter the pieces below or to break the bolts which connected them); two other similar pieces were then placed near the top of the "montant" piles, one foot above high-water mark, and the whole of them were screw bolted to the oak pile behind it; when these panels were fixed around the inner row of oak piles, the sheet piles were driven so as to fill each, commencing at each end of them, and continuing towards the centre, the last or centre pile being wedge-shaped; the others were hewn and jointed, with parallel sides, by means of a plane, they were sharpened like a wedge, and bevelled on one corner, to force them into their places against the adjoining pile; although not shod they were driven to the rock.



The sheet piles of the outer row were of the same dimensions as the inner row, but they were only thirty six feet long; they were prepared and arranged in the same manner as those of the inner row, but they were not driven to the rock. See fig. 2.

An earnest desire to husband the company's funds as much as possible, was the leading motive for using short piles for the outer side of the dam. It was hoped that if these were driven a few feet (12 to 15) into the muddy bottom of the river, they might prove to be sufficient for the support of the puddling, at least until the interior of the coffer-dam should be so far emptied as to cause the preponderance of pressure to proceed from the outside towards the interior, and the experiment was the more readily attempted, inasmuch as the means were at hand to give additional strength to this part of the work. It proved, however, that the outer row of piling ought to have been driven to the rock.

The ram used for driving the sheet piles weighed 1,300 lbs.; two pile drivers were employed driving the sheet piles, one worked in the ordinary way by a crank, the other by a tread-wheel; the latter proved to be so superior, that the former was altered into a tread wheel. The crank required eight men and a superintendent, and made a blow from the top of the planes (40 feet) in seven and a half minutes, while the tread-wheel required but six men and a superintendent, and made a blow from the same height, and with the same weight, in one minute and fifteen seconds. The horse pile drivers made a blow in one and a half minute.

Both rows of sheet piling being completed, ties of eleven inches square pine timber were put in to connect them together; these ties were placed twelve feet apart, and were dovetailed into the heads of the sheet piles; this, from the apparent stiffness of the oak and sheet piles was deemed to be sufficient, but when the puddling came to be thrown in, the weight of clay forced the outer row to spring out, drawing the ties through the dovetails. Additional ties were therefore put in at every other oak pile, and they were notched on to the "montant" pieces, and secured down by rag bolts, and even these were found not to be sufficient to hold the rows of piles together, for as the puddling advanced, in many places the ends of the ties split off, and it became necessary to pass long and strong screw-bolts through the stringers of both rows of piles. This being done, the dam might have been deemed to be secure, but it even became necessary, as an additional security, to place stringers outside of the sheet piles, to notch them on to the ties, and to rag bolt them down entirely around both the rows, and even to place three long ties of fourteen inches square timber entirely across the dam, to keep the long sides together; this was done by driving two oak piles contiguous outside, and touching the outside stringer, two others immediately opposite on the other side of the dam, each pair of piles being connected together by a stout piece of timber across and bolted to them; the long ties which crossed the dam, were formed by scarping timbers, were notched on to the cross pieces, and secured to a pile at each end by stout iron straps.

These securities were the more necessary, because the stringers, ties, &c., were of white pine, which had been left in the circular dam, and which it was necessary to use.

(To be continued.)

REVIEWS.

Public Works of Great Britain. Edited by F. W. Simms, C.E. London: John Weale, 1838.

(Third Notice.)

The second division of this work is on canals, bridges, river walls, and the docks and port of Liverpool. The six first plates show the construction of the *Thames and Medway Canal and Tunnel,* executed under the direction of W. Tierney Clarke, Esq.; the description accompanying the plates describe the mode of working the tunnel, which passes through chalk and Fullers' earth; it also gives a description and drawing of the transit instrument used by Mr. Clarke for setting out the line of the tunnel, which method is now very generally adopted in setting out the direct line, and establishing the working shafts of such tunnels as are of considerable extent. The next plate shows the construction of the *Harecastle New Tunnel,* in Staffordshire; it passes through quicksand, clay, marl, iron-stone, coal, rock, &c.; its length is 2926½ yards, and is bricked throughout; the height is 15 feet, and width 14 feet; the thickness of the springing walls is two bricks, the arch one and a half brick, and the invert one brick thick; throughout the whole extent of the tunnel is a towing-path 4 feet wide, carried on arches with an iron guard rail on the side. The cost of the tunnel *per lineal* yard, including shafts and every expense, was 38*l.* 10*s.* Plate 93 contains the drawing, accompanied by a description of the locks erected on the Montgomeryshire Canal; the construction exhibits considerable skill and judgment. Plate 94 contains the plan of the entrance gates to the Gloucester and Berkley Canal, also the sections of the walls to the basin and sea entrance, showing the method of setting out the curvilineal batter by ordinates. Plates 95, 96, and 97, are very beautifully engraved; they contain the detail of the construction of the river wall to the embankment of Fishmongers' Hall. Plate 98 is also very beautifully engraved; it exhibits the cast-iron piling for wharfs, &c., as adopted for the Deptford Pier. Plates 99, 100, and 101, contain the drawings, accompanied by a specification of the works of High Bridge, over the river Trent, Staffordshire, designed by and executed under the direction of J. Potter, Esq.; the bridge is iron, of one segmental arch, 140 feet span versed sine or rise 14 feet, and width 22 feet; the springing of the arch is 5 feet above the water line, or 15 feet above the bottom of the foundations.

"The bridge was erected in 1830; the total weight of the iron work, which was executed by the Colebrook Dale Company, is 340 tons. The whole cost of the bridge was as follows:"—

Ironwork, delivered, fixed, and completed	£3,800
Masonry	3,193
Foundations, which were piled according to the most approved method; and the approaches, which are of considerable length and height	2,500
Total cost	£9,493

The next fourteen plates contain the drawings of a variety of canal bridges, locks, gates, and canal boats. The last plate of this division is a map, showing the relative situation of the docks of Liverpool and depths of the Mersey, accompanied by a very interesting account of the Port.

The first dock ever constructed in Liverpool was opened in the year 1690; and although this dock was filled up in 1827, and has become the site of the new custom house, yet the amount of dock accommodation has increased from that time until the present day, when the docks of Liverpool are so extensive, that with those now in progress they will contain a total area of water of 111 acres 4257½ yards, and presenting a broad quay space 9 miles and 83 yards long. The extreme length of the river wall, when completed, will be 2 miles and 1087 yards.

Table, showing the area of water and the quantity of quay space of the Docks, exclusive of the graving Docks, &c.:—

Names.	Area of Water in Acres and Decimals.	Quay Space in lineal Yards.

Half of two passages	0·110	74
Dock (next Clarence Dock)	6·171	738
Half of passage	0·055	37
Lock	0·725	275

The expense of executing these stupendous excavations has been immense; and it appears from official vouchers that the cost of making the Prince's Dock alone amounted to 461,059*l.* 19*s.* 4*d.*, exclusive of the land, the estimated value of which is 100,000*l.*

The mean column of water which flows into the river Mersey, at the equinoctial, or highest spring-tides, is about thirty three feet five inches; at the mean spring-tides, twenty-nine feet seven inches; at the mean neaps, fifteen feet four inches; and at the lowest neaps, only twelve feet nine inches.

The third division comprises several drawings and descriptions of turnpike roads, executed by Mr. Telford and others; also the method of coking coal, the manufacture of iron and steel, a section of the mines at Abersyctan, in Monmouthshire, and the method of setting gas retorts.

The fourth and last division of this work contains "*A Scientific, Historical, and Commercial Survey of the Harbour and Port of London,*" by James Elmes, Architect and Civil Engineer, Surveyor of the Port of London. The frontispiece contains a very beautiful engraving of the "hemisphere," projected on the plane of the horizon of London.

"It is a fact not a little interesting, and combined with our insular station in that great highway of nations, the Atlantic, not a little explanatory of our commercial eminence, that London occupies nearly the centre of the terrestrial hemisphere."—*Sir J. Herschel.*

This division contains the plans of the following docks, very beautifully engraved, viz.:—St. Katharine Docks, London Docks, East and West India Docks, and the Commercial Docks; also detailed drawings of the lock gates of St. Katharine and the London Docks; likewise the entrance-lock of the East India Dock: there is also a map or chart of the Port of London, and a plan showing the method of mooring ships in the river Thames, and likewise the manner of laying down the mooring-chains. The accompanying letter-press to this division contains a great deal of valuable information respecting the history, privileges, and government of the port, and the various docks; also tables and memoranda connected with the tides and soundings of the river:—

The following observations on the course, dimensions, inclinations and velocities of the River Thames, and the effects which have been occasioned by the removal of the old and the building of the new London Bridge, are added. They are taken from a series of experiments and observations made on the river by Messrs. George and (Sir) John Rennie, during the years 1832, 1833, and 1834, communicated to and published in the report of the fourth meeting of the British Association for the Advancement of Science, held at Edinburgh in 1834, by George Rennie, Esq., F.R.S., &c. &c.

From these excellent observations and report are deduced that the general course of the Thames is from west to east. Like other rivers, it forms the drainage of a very extensive district, by means of rivulets and streams, which conduct the waters of the uplands into one great artery or trunk, and conveys them to the sea. The total number of these affluents may be about twenty.

It is difficult to estimate the superficial extent of country drained by the river Thames, but the authors of these observations estimate it as being at the least five thousand square miles. The course of the river is very tortuous and winding, particularly between Deptford and Blackwall, and is double

its length, circuitously, of its distance from its source to its mouth, measured by a straight line.

The navigable distance from London to Lechlade is about one hundred and forty-six miles and a half; but from Sheerness the total distance is two hundred and four miles and a half. The total fall of the River from Lechlade to low-water mark, is two hundred and fifty-eight feet, or twenty-one inches per mile; and this fall is nearly uniform, although there are places where the fall varies from nineteen inches to thirty-two inches per mile, as shown in the following table, calculated by those gentlemen, who observe, that in no instance is the funicular curve of M. Gerard established.

"The velocity of the Thames might be expected," says Mr. George Rennie, "to follow the law of variation of the inclinations; but that the natural obstructions which exist in all parts of the river upwards, from bends, shoals, islands, weeds, &c., and the artificial obstacles from weirs, pound locks, fishing ayts, &c., render it impossible to ascertain the velocity correctly. Much depends also upon the volume of water passing down the river, and the use of *flashes*."

In general, the velocity may be estimated at from half a mile to two miles and three-quarters per hour; but the mean velocity may be reckoned at two miles per hour. In the year 1794, the late Mr. Rennie found the velocity of the Thames at Windsor two miles and a half per hour.

Sir John Hall, the active and intelligent Secretary of the St. Katherine Dock Company, has given the following information relative to the influence of the wind upon the tides in the Port of London to Mr. Lubbock, who has thought it of sufficient importance to print in his communication to the Royal Society in 1834. Sir John Hall procured the joint opinion of some nautical men, including Captain Compton, the Dock-master of St. Katherine Docks, and Captain John Fisher, R.N., the Superintending Harbour-master of the Port. The following is the result of their sentiments respecting the influence of the wind upon the tides in the Port of London.

During strong north-westerly gales, the tide marks high-water earlier than otherwise, and does not give so much water, whilst the ebb-tide runs out later and marks lower; but upon the gales abating, and the weather moderating, the tides put in and rise much higher, whilst they also run longer before high-water is marked, and with greater velocity of current; nor do they run out so long or so low. The reason assigned for this is, that the strong north-west winds drive the sea along the Dutch coast, through the Straits of Dover, and, consequently, away from the mouth of the Thames; so that the tides, during north-west winds, are always much higher on the Dutch coast, producing frequently ruinous flooding thereto, than upon the English coast. A south-westerly gale has generally a contrary effect, and an easterly wind gives some water; but the tides, in all these cases, always improve the moment the weather moderates.

Pursuing the subject in relation to the Port of London, Mr. G. Rennie observes—"That in the river Thames the motion of the current continues for some time after the tide has made its mark, which is undoubtedly owing to its momentum. In general, the tides of the river Thames have been found to observe considerable regularity, both in their elevations and periodical times, except when influenced by winds and floods. In comparing, however, the sea tide with the river tides, a considerable discrepancy is found to prevail in the elevations; in some cases, on account of the convergence or swelling of the tidal wave, on the principle of the conservation of mechanical force, as in the Severn, &c.; and in other cases a lowering of the surface by expansion, as in the Mersey, which is very narrow at its mouth."

Account of the Inaugural Meeting of the Society for Promoting Practical Design, &c., held at Exeter Hall, Jan. 11, 1838. London.

THIS pamphlet commands our most cordial recommendation, on account of the exceedingly great importance of the subject brought forward in it, which, though at first sight it appears to extend no further than the question, whether it be practicable to infuse better taste among the artisans employed in our manufactures, is one intimately connected with the commercial interests and prosperity of the country, and also with the moral habits and feelings of the people generally. Nor do we relish it the less, because, instead of being glossed over, and decked out altogether *couleur de rose*, our deficiencies, as a nation, in respect to art, are probed somewhat unsparingly by Mr. Wyse, the Member for Waterford, in the powerful and brilliant speech in which he addressed the meeting, and which, for its luminous, statesman-like, and philanthropical views, seconded both by intimacy with the subject itself, and nervousness of diction, can hardly fail to be perused with admiration. There are, it is true, a class of persons, namely, those whose pseudo-patriotism, cheap, ready-made, and warranted to look like genuine, who will, no doubt, be scandalized at finding a so much higher rank assigned to foreigners as regards all those productions of industry that stand in any degree of relationship to those of art: such persons are indeed at liberty to consider what is here said on that head as no better than slander towards ourselves; or they may comfort themselves and those who will listen to them with the idea, that while we are decidedly superior to all the continental nations in the material and skilful fabric of our manufactures, it is of little moment though we fall far short of them in what belongs merely to external appearance and taste. Yet even admitting we can very well afford to be satisfied with that intrinsic advantage over our rivals and competitors in the market, we cannot assure ourselves how long it may continue, nor that other nations will not, ere long, equal us in those mechanical branches of industry wherein we now surpass them, and thereby turn the scale altogether in their own favour; should not we in the meanwhile make some effort towards competing with, or rather excelling them, where they at present greatly excel us? One leading step, in such course, is to inquire unflinchingly into our own deficiencies, to set about rooting out the fallacies, deceptions, and prejudices which blind us to them, and to apply ourselves strenuously to the task of improvement.

It is undeniable, that in this country the arts have been looked upon as matters of mere luxury, as designed to minister to the enjoyment of those alone who can afford to pay for them; in short, as what does not in the least concern the working classes, can either interest them, or ought to be allowed to do so. This churlish spirit has manifested itself more than it ought to do, even among those who have, as far as purchasing liberally and paying large prices to artists go, been patrons of art in the most limited and vulgar sense of the terms. In this country the wealthy seem to collect only to entomb, while by permitting others freely, though under proper restrictions, to participate in their treasures of art, they would, in fact, gain much more in the character of the possessors of them, than they now do by the exclusiveness with which they keep them to themselves. One would imagine that a refined selfishness, if no better motive, would induce the owners to be less niggardly in allowing access to what, by being enjoyed by others, would not be at all decreased in itself; but rather confer upon themselves, in consequence, additional importance in public estimation. An Englishman, however, seems to be of opinion, that were he to allow his inferiors at all to participate with him in his taste for art, he should lower it, tacitly admitting that those so much beneath him could derive enjoyment from the same refined and intellectual sources as himself. Hence, although England is a nation famed for its charitableness, its charity extends no further than assisting the poor in their bodily necessities, as if they were mere animals which ought to be satisfied if their hunger be appeased, having no right to anything that looks like mere enjoyment or amusement. No wonder, then, that as Mr. Wyse remarks, "there seems to exist not only no connexion, but a sort of hostility between the upper and lower classes of society in this country." There are, indeed, little other points of contact between them, than when the former disgrace themselves by lowering their tastes and pursuits to the level of those of the most brutal and vulgar of their inferiors—prize-fighters, horse-jockeys, and gamblers. Unfortunately, none seem to care to show any sympathy with the lower orders, by affording them the opportunity of raising themselves up to them in any degree, as far as intellectual tastes are concerned.

Undoubtedly, one main cause of the sullen indifference to art which characterises the bulk of the people in this country, is to be found in the spirit of Protestantism; yet that would seem to be only an additional reason wherefore we should afford the people those facilities for an intercourse with art, which our national religion withholds from them. Instead of this, we have hitherto actually excluded them from the only two churches in the metropolis where there was any chance of their contracting any acquaintance with works of sculpture—St. Paul's and Westminster Abbey; and even now their doors can hardly be said to be freely opened to them. Had it been our express object to deter the people from in any way familiarizing themselves with art, hardly

could we have devised a system more effective for such purpose than the one tacitly adopted and pursued by us. How widely different all this from the practice of Italy, and other foreign nations, where, as Mr. Ewart observed in his speech, "galleries of art are freely, I might almost say, solicitingly open to the peasant as well as to the prince." So, too, as a female traveller has informed us, she met with groups of Bavarian peasants gazing on the frescos and reliefs in the splendid saloons of the new palace at Munich, adorned by the pencils and chisels of such artists as Cornelius, Schnorr, and Schwanthaler.

Fully do we agree with the same gentleman, when he afterwards says, "to enlighten and refine the public, by means of galleries of art, is in all cases desirable; but how much more desirable in climates such as ours. In ancient Greece, or in modern Italy, the out-door walk of a citizen would afford him a practical lecture on the principles of art"—(this is "Trade," in the original; but must be a misprint, which has been corrected accordingly,) "and the elements of design." Such are the external advantages of climate! Classic groups and classic bas-reliefs stood then beneath their noblest theatre—the open sky. Here such out-door exhibition is denied us; its place ought, therefore, to be supplied by exhibitions within doors. The portals of the arts should be liberally and gratuitously thrown open to the people." The exclusion of the people from any intercourse with art has operated injuriously in more ways than one, since it has driven them to coarse, brutalizing indulgences, as well as prevented them from competing with foreign artisans in all articles of fancy and taste; so that let the wealthy classes be ever so refined, as they do not design their own ornamental luxuries, they must, of necessity, either content themselves with costly but comparatively inelegant productions, or else supply themselves from continental markets. "Of the bronzes produced in this country," says Mr. Wyse, "placed beside those of France, and still more of the Prussians, our's are to be considered merely like Peter Pindar's razors, made to sell and not intended as works of art." Let us hope that this state of things will now be reformed, and that to our confessed superiority in the *utile*, we shall now strive to superiority in the *dulce* likewise. It is something to know, that a beginning has been made; and all success, we trust, will attend the Society for Promoting Practical Design, and others that may emanate from it. We have not, indeed, entered into particulars respecting it, because we hope that the pamphlet itself will be in the hands of all our readers, it being one that deserves to be most widely circulated and brought into notice.

Berlin und seine Umgebungen, &c.—Berlin and its Environs in the Nineteenth Century; a Series of Views engraved on Steel, after Drawings by Mauch, Gärtner, Biermann, and Hintze. With Historical and Descriptive Accounts. By S. H. Spiker, Royal Prussian Librarian. Berlin, 4to.

In the mode of its getting up, this work resembles "London in the Nineteenth Century," and "Pugin's Paris," there being two views on each plate; and as it is likewise *en suite* with them in its size, it may be considered as a contribution towards a general series, illustrating the architectural features of the capitals and principal cities of Europe; although such series is at present merely an imaginary one, and we fear likely to continue so; yet, if we may not hope that the other cities of Germany—and not those of Germany alone—will follow the example here set by Berlin, it is not too much to expect that some of our English publishers should send out an able architectural draughtsman to Munich or St. Petersburgh, at either of which places he would find ample employment for several months, without having occasion to wander about in quest of subjects which had escaped other pencils. Even Paris would by this time furnish quite a fresh harvest since Pugin's work made its appearance; for there is now the Arc de l'Etoile, La Madelene, l'Ecole des Beaux Arts, and we know not how many other splendid edifices that are either now at length completed, or that have been commenced and finished long subsequently to the date of the work above mentioned. But why should we refer to Paris, when there are Bordeaux, Lyons, and so many other places in France, that may be said to be kept veiled from us? Then, again, are there not Genoa, Milan, Vicenza? yet what English artist seems to think the palace-lined streets of the first, or any of the edifices of the two latter, except indeed it be Milan Cathedral, worthy of being commemorated by his pencil? That no one should have cared to exhibit to us any of Palladio's buildings either at Vicenza or elsewhere, as they actually show themselves, and set off, as they might be, by picturesque effect, in addition to the accompaniment of locality, is indeed extraordinary; all we can say is, that such neglect of them serves as one tolerably convincing argument among others, that they are sadly deficient in those enchanting qualities so liberally attributed to them by guide books, and by critics of a certain class. No, our sketchers and topographical likeness-takers have no eyes for Vicenza, or for Florence; neither have they for Venice, except it be for St. Mark's and the Doge's palace; nor for Naples, except it be for its bay. Between those two cities they behold nothing save Rome, the Eternal City, with which they contrive to bore us eternally, bringing home with them either views of buildings drawn over and over again before, or else mere scraps and bits—an old wall and some trees, with a group of figures, or something of the sort, that may possibly exist somewhere in Rome, yet are not a whit more interesting, instructive, or picturesque, than a hundred other old walls and trees that might be discovered without hardly wandering beyond the bounds of the bills of mortality. But we are waxing quite cynical, besides being in a very fair way of losing our way altogether, therefore let us betake ourselves back again to Berlin, with a speed far excelling that of all the steam-engines and railroad carriages in the universe. Hardly need we say, that Berlin contains many fine pieces of architecture, including one or two of Schinkel's masterpieces; among which, the first place must be assigned to the Museum: of this there are two views, one showing the entire façade, the other a partial and nearer view of it, with, in the foreground, the huge granite tazza in front of the flight of steps. Unfortunately, however, these two plates happen to be executed with less taste and intelligence than almost any others in the whole work. They serve, indeed, just to convey a general idea of the building, and no more; yet had it been ably treated, the view in which the tazza is so conspicuous an object, would have formed a most beautiful composition. As our readers may probably be curious to learn something of this enormous *tazza*, we may as well inform them that it is worked out of a single block of granite, found on the summit of a hill near Furstenwald, and is twenty-two feet in diameter. It was commenced in May, 1827, and brought to Berlin in the November of the following year; after which, the finishing and polishing it occupied two years and a half more. While it was in progress, forty-four of the workmen had a breakfast given to them in it, and were all able to seat themselves without the least inconvenience. The Museum itself is now pretty well known to English architects, by the designs of it in Schinkel's "Entwürfe," and also by what has been said of it in a paper on modern German architecture, in No. 27 of the "Foreign Quarterly Review."

The work contains several views of buildings at Potzdam, including the lately erected Nicolai church, designed by Schinkel, together with Charlottenhof, and some other villas in the environs. The view of the Gärtner-wohnung, or Gardener's residence at Charlottenhof, is one of the most striking and best executed plates in the work—most picturesque in point of subject, and clear and sparkling in effect. In fact, the whole scene itself might easily be mistaken for some refined ideal of an Italian or an Arcadian dwelling, with an open bower-like hall, partly shrouded by the luxuriant umbrage of vines, mantling its roof with verdure. Schinkel—for this is also a conception of his—has here displayed the versatility of his talent, and his power of imagination, with great geniality. It is, in short, just what one would picture to himself as the embellished residence of a poet or an artist.

Several of the plates are executed by Finden, and other English engravers; and among those by the one just mentioned is the view of the Mausoleum, erected to the late lamented Louisa of Prussia, of whom the interior contains an exquisite recumbent statue by Rauch, universally allowed to be one of the finest specimens of modern art. On each side of this figure stands a marble candelabrum, one of them embellished with a group representing the Fates, being by Rauch himself, the other similarly decorated with a group of the Horen, or Hours, being by Tieck, the brother of the poet, and one of the most eminent living sculptors in Prussia. We learn from the account accompanying this subject, that the statue was executed by Rauch at Rome, and that the vessel in which it was shipped was captured in the British Channel by an American one, but afterwards retaken by the English off Cadiz. The Mausoleum itself, which was erected by the late Ober-Baurath of Genz, the architect of the Mint at Berlin, has a tetrastyle Doric portico, executed in a reddish granite, and each column consisting of a single piece.

In one respect this work differs, and very materially for its advantage, from similar ones published in this country, namely, in the satisfactory character of its letter-press, which contains a great deal of desirable information; while that which for the most accompanies our English publications of a similar class, is either provokingly meagre, or made up of rambling, desultory matter, having but a very slight connexion with the objects purposed to be spoken of, and sometimes nearly passing them over altogether. The letter-press to Pugin's "Paris" is, for instance, most shamefully done in many parts; not only without anything approaching to criticism or remark, but abounding with actual blunders. Spiker's Berlin, on the contrary, is a really interesting accession to German topography.

Cheffins' Official Map of the London and Birmingham Railway, and adjacent Country.

Cheffins' Official Map of the Grand Junction Railway, and adjacent Country.

These two Maps are published by the authority of the two railway companies. They are very minutely and accurately drawn to a scale of half an inch to a mile; every station, tributary railway, village, market town, park, and other object worthy of notice within the distance of thirty miles of either railway, are clearly shown, together with their distances from the stations. Annexed to each map is a section showing the gradients and levels of the country through which the lines pass. Besides the above two official maps, Mr. Cheffins has had them reduced to a small scale, suitable to the pocket both for convenience and price. We strongly recommend these maps to every commercial house, and persons who are trading with any of the great manufacturing towns on the line, as they give a clear view of the relative advantages of the line for the convenience of sending goods, or travelling. The smaller maps should be in the hands of every person who intends to travel on either of the railways.

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS, No. 4.

COLLEGE OF SURGEONS.

"The most striking instance of Attic elegance, debased by meanness of application, is to be seen in Lincoln's Inn Fields, where an Ionic portico of majestic dimensions, and exquisite individual beauty, is attached to a front with which it has no more legitimate connexion than the helmet of Pericles with the head of a Quaker." It is thus that Mr. Wightwick, in his "Sketches by a Travelling Architect," briefly characterizes the original front of this edifice, which has, happily, been superseded by the new and extended façade given to it by Mr. Barry. How far the building now satisfies Mr. Wightwick I cannot judge; but I have met with some who are of opinion that the change has not been an improvement, on the grounds that in its first state the portico showed itself to far greater advantage than at present, and far more conspicuously.

That it showed itself most conspicuously and strikingly, cannot be denied, for it showed like a piece of velvet or brocade patched upon a coat of drugget. It was, in truth, a most choice morceau, a delectable tit-bit for Welby Pugin, whom it would fully have borne out, even far better than anything he has actually made use of in his "Contrasts"—better, infinitely better, than King's Cross, because it showed that even while copying a fine antique specimen, the architect had not the slightest feeling for or intelligence of it—not an idea in common with it; whereas, abominable as it is, the other has the merit of being consistently so—all of a piece, and in equally bad taste throughout. Except the portico, all the rest was not only plain, but absolutely paltry and mean, without the slightest evidence of taste in any part or feature, or in any one respect. It would have been ugly enough without the addition of the columns in front of it; with that addition it was an intolerable bungle—a first-rate architectural monstrosity. Independently of appearance and design, it was obvious that the house neither suited the portico, nor the portico the house; though it would have greatly puzzled a stranger to determine whether the house was built first, and the columns tacked to it afterwards, or *vice versa*. Most assuredly, however, he would never have imagined that the one was intended to be associated with the other, or erected by the same builder—architect he cannot be styled.

Greatly as I rejoice that that hideous front has disappeared, I am not at all sorry that a memento of it is preserved among the views in Jones's "London," because it bears testimony to the justness of my remarks, and to the skill and taste Mr. Barry has displayed in metamorphosing it into harmony and beauty; so that it now deserves to have the title of one of Byron's productions conferred upon it, and to be henceforth designated "The Deformed Transformed."

All this is easily said; it amounts to nothing more than an avowal of decided dislike, akin to that expressed in the well-known lines—"I do not like thee, Doctor Fell," &c. Now, mere liking or disliking is not criticism; therefore, unless I can bring forward some kind of reasons and proofs—be they good or insufficient ones—in support of my allegations, I might as well keep my opinion to myself, or the reader might as well take that of the first person he should meet in the street. Yet, sorry am I to say (as I here do, *par parenthèse*), that of so-called criticism, more especially architectural criticism, a very large proportion must be saken upon implicit trust. "This is exceedingly fine—that is detestably bad," so sayeth Critic; yet, wherein the excellence or the vileness consists, people are left to puzzle themselves to make out—for the reason that it would strangely puzzle Critic himself to explain it to them, and that is the only reasonable part of the business. In more than one instance, my predecessor, Ralph the First, has shown himself to be a critic of that stamp; to wit, when he assures us that the east of St. Martin's Church is "remarkably elegant, and very justly challenges particular applause," yet evidently did not think it worth while to point out to the less discriminating in what its "remarkable elegance" consists; owing to which truly unfortunate reticence on his part, I, his unworthy successor, for one, have never been able to discover it.

After this small digression—whether an impertinent one or not, the reader will decide according to his own fancy—let us return to our *muttons*, as the French phrase expresses it.

Independently of the utter dissimilarity of character between the portico and the building behind it, in the old front, there was no due relative proportion as to size. The colonnade was either too long or too short; as a central feature, it was the former; as more than that the latter, since it stopped short, leaving only a very insignificant bit on each side of it. The same holds good in respect to height: as a mere porch, subordinate to the general mass, it was too lofty; while as the order marking the principal mass, it was too low. The parts behind it did not rise up as an attic superimposed on the portion connected with the order; neither did they (as they have since been made to do) constitute a main edifice, to which the colonnade was to be considered only secondary. In regard to design, it was no more than a wall with so many naked openings for windows, some square-headed, others round—a proof, perhaps, that variety had been studied—and two of them so placed, that had the lines of the cornice to the portico been continued as they now are, they would have cut them. Those windows, therefore, more ingenuously than ingeniously, indicated that there were some *entresol* rooms, against which the cornices alluded to came nearly midway. Perhaps I might have spared myself the trouble of saying the "cornice alluded to," because other cornice there was none; the building presented no indication of being terminated and completed, but was, architecturally considered, a mere crude and *inorganized* mass. Now in itself this might have been endured, excused on the score of economy, and only negatively defective. It becomes a very different matter, when to this excessive homeliness and dowdiness is added the parade of a portico. The whole is then rendered a ridiculous compound, exhibiting blundering pretension, false and beggarly niggardliness, with equally false and beggarly dignity. A person in a drayman's or dustman's jacket, with half a dozen footmen in laced liveries behind him, would not be a whit more preposterous. No; if the College wished the architect to make their house a little smarter, he should have recommended to them a modest porch below, and a *neat* viranda—something of that sort, spruce and *Londonish*. Truly it was a most *owlish* affair for him to go to Athens, *i. e.*, to Stuart's "Athens," in quest, I will not say of a model, but a pattern for a row of columns, which, without the least adaptation, I might say without taking the trouble to adjust to his building (for as a cloak, surtout, or what is called a *cover-slut* to it, it was too scanty), he claps in front of it. Why, even a female artist would not betray such disregard to propriety and unity; a milliner would not recommend a full-dress cap as a part of breakfast-table costume, or a velvet cloak, trimmed with ermine, to be worn with a dress of very ordinary materials.

Economy and taste were both outraged and scandalized in the first design for the College of Surgeons; since where was the economy of erecting a naked front, begrudging it the slightest degree of ornament, yet afterwards flinging away a sum greater than what was so saved, by attaching to it a superfluity, an excrescence, a contradiction? Such a proceeding is the very reverse of economy. That the architect should have suggested—or if he did not himself suggest, have listened to so preposterous an idea as that of *doctoring up* his design with such a colonnade as he applied to it, was the less excusable, and argued utter barrenness of invention, as there was his bare wall of a front for him to operate upon, to fill up, plump out, and put into good condition, in contriving which he might have given free scope to his imagination, supposing him to have possessed a particle of it. Neither can I believe that the College would have refused to listen to his remonstrances against the portico, had they been properly urged; since those gentlemen in this case became the patients, and in such capacity would hardly have insisted upon acting so contrary to all medical precedent and etiquette, as to write their own architectural prescription, and leave the doctor whom they had called in nothing else to do but to perform the office of apothecary and make it up.

But come, this reads too much like a long parenthesis crammed with satire. The "*Friends to Liberal Criticism*" will never endure this—perhaps not even comprehend it. Therefore *allons*: within this *classical* portico there was no central doorway, but an arched window in the middle, with a snug arched door with a fan-light—just such as

would built a stable, or some building of that kind—on each side of it. How well these comparatively diminutive arched holes in the wall accorded with the columns paraded in front of the building, may easily be conceived. Independently of this, there were evidences of bad taste that would have been offensive had there been no columns at all; for the arched head of the windows was divided by the upright style of the folding sashes being continued, and thereby producing a most harsh and disagreeable effect, the semicircle being cut into two quadrants.

"But the order itself, good critic, was not that admirable—quite a specimen of Attic elegance, as Wightwick says?" Softly, of that I will not be quite positive; to confess the truth, I have my misgivings on that point. As far as general form and expression went, undoubtedly such was the case; indeed, it would have required some ingenuity to miss such a degree of the original character, the columns being in their proportions and contours nothing more than express copies; and every one is aware that architectural copying of such things is altogether a mechanical affair—nothing else than adhering to the proposed pattern already set. But the order was exhibited stripped quite bare, and its members denuded of all finish, so that it preserved no other characteristic of the original than the voluted capitals. All else was impoverished even to chillingness—a mode of proceeding directly the reverse of that pursued by the Greeks, whose practice it was, as we now well know, to treat their primary architectural forms as a ground-work for embellishment, not of sculpture only, but of colouring likewise. Yet, as if it was not sufficient that the order should be shorn of all finish, and rendered as bald as possible, it was *barbarised* still further, by the addition of a monstrous oval shield and its supporters, apparently the design of some artist in the Heralds' College, which was stuck up over the centre of this *soi-disant* Attic colonnade. Peace be with it! it is now defunct and gone, and may we never clap eyes on its like again.

Such was the wretched front which Mr. Barry was called upon to throw into Medea's caldron, and metamorphose into a pile fraught with harmony and beauty. He has performed his task most ably, and now that it is achieved, it may appear to have been very easy; yet, I very much question whether many would have accomplished it half so well, though there can be no doubt that almost any one could have made something many degrees superior to the first building, its faults being so very glaring and outrageous. Yet although the new architect had thus much in his favour, that the front was to be extended, he was also trammelled by the circumstance that the portico was to be retained, and was of course obliged to regulate his design and the character of the whole building accordingly. As the additional extent was given by taking in the adjoining house on the east side, this of course threw the portico out of the centre, yet it fortunately happened that uniformity could be again restored by merely taking down the column at the west end of the portico and removing it to the other angle, leaving all the others untouched. To carry up the same portico higher was impossible, therefore Mr. Barry very judiciously decided upon treating it as an adjunct to the building, making the latter principal and the other secondary in his design; yet this did not deter him from fluting the columns, and enriching the mouldings of the entablature, as he was aware he could sufficiently counterbalance such degree of decoration there by the depth and richness he intended to bestow on the *cornicione* which crowns and finishes the whole mass. Indeed, had he not so finished up the portico, it would either have looked far more bare and cold than at first, owing to being contrasted with the exceedingly rich line of cornice above it; or else he must have greatly moderated that cornice, out of discreet regard for the portico itself. Had he, however, adopted this latter course, the result would have been, that instead of forming, as it now does, a fine termination to the whole composition, and imparting to it an air of unusual dignity, the upper cornice must have been considerably reduced, and would no longer have been of sufficient consequence for its important situation. The extension of the front, and thus gaining an additional window on each side the portico, to say nothing of expunging those which before intruded themselves between those of the second and upper range, has materially benefitted not only the general design, but the portico itself. The only thing which, in my opinion, operates rather as a drawback on the merits of this façade is, that the windows are rather of too plain a character for the rest. I could, therefore, wish that the architraves of those on the ground floor and the one above it—those at least external to the portico, had had somewhat bolder and richer architraves, so as to have been more in keeping with the decoration bestowed elsewhere.

There are two things, however, which deserve to have attention particularly directed to them, being of a kind apt to be overlooked, and certainly not sufficiently attended to by architects themselves, viz. the chimneys, and the piers separating the court from the street. The first are happily imagined, and tell very effectively in a side view of the building. The others exhibit a most elegant mode of decorating by rustic work, or rather tooled surfaces, so as to produce an effect at once delicate, picturesque, and rich. The interior of the building is also exceedingly well worth seeing; but it is time for me now to conclude, neither will my silence in regard to it prove a very serious omission, since it has been very fully described in the last volume of the "Companion to the Almanac."

PHILOTECHNICOS, No. 3.

Stained Glass.

The splendid effect produced by the use of stained glass is too well known to need our eulogy, for who that has visited any of our cathedrals, has not experienced its delightful sensations? The beautiful and varied hues of the glass, which cast their mellowing tints on every object around, operate on the mind, and create a kind of reverential awe for the structure wherein their beauties are diffused, and which are so much the more in keeping, when the building partakes of a sacred character. Although this feeling exists in the mind of every man, there are but few instances in modern times where stained glass is in any way introduced, as may be witnessed in most of the new churches, for rarely do we find its introduction in any of them, excepting, indeed, where some private individual, possessing more taste than the generality of mankind, "presents a painted window to adorn the altar;" but these are instances but "few and far between;" it is but very seldom that any other than that of the common glazier is ever exercised in the windows of our modern churches, where, indeed, excessive parsimony seems to be the only order of the day. It is a fact, hardly credible, that so little is this kind of decoration patronized, that it would be difficult to find half a dozen artists in the whole country who are engaged in this branch of the arts; and even of those few, there are but two or three of any eminence. How is this, when the propriety, the aptitude, nay, the almost absolute necessity for its introduction, cannot be denied? Is not a well painted window, representing some interesting scene selected from the Scriptures, with all the brilliant variety of light and shade that glass is capable of producing, far more appropriate than the coloured canvass, which, although executed in the first style of excellence, will come far short in the comparison? England, where is thy boasted taste? where thy sons, who profess so much filial regard for ancient beauties, and regard not this? Are they among the temples of the classic land, storing their minds with the magnificent conceptions of early ages? Are they exploring those exhumed towns, Herculaneum and Pompeii, to find examples worthy of England's imitation? Or do they wander in more distant climes, to gather sweets from every land; and, when well laden, like the bee, return to enrich their homes? If so, 'tis well; but why seek they the lily and forget the rose? Have they not both attractive powers? Should not the one, of native growth, be nourished in preference to that of alien soil? Why spend thousands in a foreign land to obtain some novel beauty, while at home the loveliest is left forlorn? Yet so it is; the quays of our rivers are laden with the produce of foreign artists, when those of England are neglected, and thousands distributed abroad that might have supported numerous, and, in many respects, far more talented native artists. In no instance are these remarks more fully verified than in the present want of encouragement to the stained glass artists. Many persons have an extraordinary notion that the art of painting in glass is lost. Lost, forsooth! why the idea is the most fallacious that ever existed; and so far is it from the fact, that the present state of excellence was *never* before equalled. There is no colour under the sun, not even the boasted ruby of the ancients, but can be imitated in stained glass—blues, from the palest steel to the darkest purple; rubies, from the lightest pink to the deepest scarlet; and, in fact, every variety of tint and colour can be produced by the artists of the present day, and not in separate pieces only, as did the ancients, but on one and the same piece. The old method of painting consisted in having a separate piece of glass to each colour, and shading it with brown, which was the only colour that they used with the pencil, consequently they never could aim at perspective. Their pictures are all flat surfaces, divided into an infinity of parts, and without the least pretension to drawing, as may be seen upon examination of any of the great windows of our cathedrals, and particularly at King's College Chapel, Cambridge, where the effect, with all these deficiencies, is beautiful; and yet it is with the utmost difficulty that the outline of any of the subjects can be traced. How different are the productions of the present day, where perspective, good drawing, and *chiaro scuro* are all studied and obtained.

We have been led to make these remarks, in consequence of a recent view of a splendid window now executing for Upwell Church, near Wisbeach, under the munificent liberality of the Rev. G. Townley, by Messrs. Hoadley and Oldfield. The window is twenty feet high and twelve feet wide, divided by mullions into three compartments, to be filled in with scriptural subjects; the centre is taken from Spaniolette's clever picture of "Christ's Descent from the Cross," the full size of the original, viz. eight feet six by five feet eight; and those on the sides represent "Christ Appearing to Mary Magdalene," and "His Bearing of the Cross;" the upper part is filled in with ancient Gothic canopies, and the sacred emblems of the cup, the shower of manna, the brazen serpent, the celestial crowns, the cloven tongues, the rock of Moses, &c. The part already executed of this splendid work is of such a superior and masterly style, that it defies the pen to write in words of sufficient praise; the immense depth of colour—the natural fleshy appearance of the face and hands, the expression of feeling, the boldness of the drapery, and, above all, the awful and deathlike appearance of the Saviour, is superior to any thing of the

kind which we have ever beheld. The deep blue and the ruby are here seen to vie with any early production, and not executed, as in those times, in "pot metal," but actually enamelled on the glass. The lights are thrown in with such brilliant transparency, that they illumine the whole subject, so as to produce in the mind feelings of the most intense interest. We sincerely hope that before this *chef d'œuvre* of art is removed to its destination, that the reverend gentleman for whom it is executed will permit it being exhibited in the metropolis, and let the rich and liberal-minded know that we have in England artists equal in talent to any in the world, and capable of producing works of almost unlimited beauty.

The many other beautiful specimens of stained glass produced by these artists would really deserve a separate notice for each, were it not for the fear of occupying too much space; we will therefore only briefly notice a few of them, and perhaps the one of "Belshazzar's Feast," after Martin, may be considered the most interesting; the size is thirty inches by nineteen. The figures are drawn in with the most minute and astonishing correctness, and the magnificence of the architecture and surrounding scenery is wonderfully enhanced by the modulation of tints, consequent upon the use of so transparent a medium as glass. It is painted upon one sheet of glass; and for variety of hues, brilliancy of effect, and excellence of workmanship, perhaps was never before equalled. This *ne plus ultra* of art was purchased by the Duke of Northumberland; and in order to preserve it from damage, it was enclosed between two thick sheets of plate glass, and secured in a strong frame. A second copy was likewise painted by the same artists, and purchased by an *American!* Several other subjects were painted by the same artists, after Martin, among which were "The Fall of Nineveh," "The Opening of the Sixth Seal," "Joshua commanding the Sun to stand still," and "Love among the Roses;" a series of the most perfect gems that can well be imagined.

Harlow's "Kemble Family" was likewise imitated with equal ability, and coloured after the original, the dimensions of which are thirty two inches by twenty-two. Besides the above, Messrs. Hoadley and Oldfield have painted numerous subjects for church windows. Those of "Faith, Hope, and Charity," after Sir Joshua Reynolds, claim unqualified praise; the exquisite beauty of the female forms, endearing simplicity of the children, the depth of colour, the graceful folds of the drapery, and the purity of taste exhibited in the canopied enrichments, are really the *coup de grace* of excellence.

These artists have painted four sets of the figures—one, for Charles the Tenth of France, which obtained the gift of a medal from the French Institute; another for the church of St. George's in the East; another for the New Church, at Calcutta; and the fourth they have still in their possession. The large window in the new Margate Church, of Gothic foliage and other ornament, was also from their hands. In imitation of the old style, they have painted two large windows in Petworth Church, representing angels surrounded by Gothic foliage; and so exact is the representation of the ancient character, that it is almost impossible to discover them to be of modern production. We could enumerate many other paintings of great beauty and excellence, by which we have, at various times, been gratified with the view of, by the kindness of Messrs. Hoadley and Oldfield, who lately publicly exhibited several of them in Regent Street, and at their own residence in the Hampstead Road.

We cannot leave this subject without expressing our admiration of that splendid work of art, "The Field of the Cloth of Gold," exhibited some years since in Oxford Street, but unhappily destroyed by that uncompromising element, fire. It represented one of those splendid tournaments in the time of Henry the Eighth. The portly king, accompanied by Cardinal Wolsey and his other usual attendants, were seated in the rear, to view the gorgeous pageant that occupied the foreground, where the armour-clad knights were preparing for the tilt, and encouraged by the bright eyes of the many lovely ladies of the court, by whom they were surrounded. The *coup d'œil* of this picture exhibited a mass of gorgeous magnificence; every depth of tone and colour were seen in the several details; the splendid dresses of the females, the polished surfaces of the armour, and the whole of the "trappings of royalty," were depicted with wonderful brilliancy and effect. This window was the production of Mr. Wilmshurst, assisted by Mr. Bone and several other eminent artists, and intended for a baronial hall; it was purchased on speculation, and for some time exhibited before it met with its untimely fate.

The process by which the painting in stained glass is produced is as follows:—The glass, which is the best Newcastle crown (and not too thick, or it will be liable to fly in the firing), is first coloured with a light neutral tint for the ground; the outlines are then drawn in on the reverse side in Indian ink; it then passes the fire, which must be done with great care, as the heat must be so nicely regulated, that the glass may not be liable to melt, which would be the case if the furnace were too highly heated; and on the contrary, if the furnace be not sufficiently heated, the colours will not fix. The fire is then allowed to go out, and the glass gradually cooled; it is then taken out and placed against a large sheet of plate glass, supported by a frame easel, against a strong light; the stains are then put in, with the lights and shadows in enamel, and again passed through the fire; these tints and shadows are strengthened several times, passing the fire each time, until the proper depth be obtained. The picture is usually divided into several pieces of different shapes and sizes, according to the form of the outlines or shadows, and put together with lead, and so completely are the joints usually concealed, that the whole picture has the appearance of one extensive sheet of glass.

The colours are prepared from oxides of different metals, combined with fluxes, but neither those of vegetable or earthy bases will answer the purpose, as they volatile in the fire.

Embossed Glass.

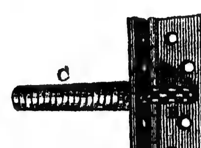
This kind of glass has the appearance of burnished and dead silver, and produces a chaste, quiet, and elegant effect, and when applied to Grecian ornament is in beautiful harmony with the graceful outline peculiar to that style. It is simply prepared by drawing the outline of the ornament in Indian ink, and filling up the ground, on the reverse side, with a coat of varnish or prepared wax, and when dry, passing over the whole a solution of fluoric acid; this acid acts upon the uncovered surface of the glass by eating away the face, the whole is then washed, the varnish or wax removed, and the raised surface rubbed, which produces the appearance of ground glass.

Messrs. Hoadley and Oldfield have executed several large windows in embossed glass, one of which was for Fishmongers' Hall. They occasionally combine the embossed, the stained, and the enamelled process, upon one surface. This they have introduced, with particular effect, in a pair of blinds at their own residence, which are fixed in folding frames to their parlour windows, and hung on hinges in the usual way.

Gerish's Patent Spring Hinge.

This is a very ingeniously contrived door spring; it simply consists of a common butt hinge with a spiral spring enclosed in an iron tube, on the principle of the steelyard, projecting at right-angles to one of the sides or leaves of the hinge, to which is attached a strong chain connected also to the opposite leaf of the hinge; this tube is either let into the door-post or jamb of the door, and otherwise fixed in the usual way; the action is obvious, that upon opening the door, the chain is drawn out and extends the spiral spring, which immediately collapses, upon the force being withdrawn, and the door closing.

The annexed engraving will show it more clearly:—



A is the butt-hinge, B the chain, and C the tube, enclosing the spiral spring. This spring hinge can be attached to any door, and either fixed in the centre between the common hinge, or in place of either of them. The cost is comparatively trifling, being about three or four shillings for the usual sized door, one of which will be sufficient; but for large doors two would be required. They are also made of brass for best rooms, and have a very neat appearance.

ON PREJUDICE AS TO STYLE IN ARCHITECTURE.

Read before the Architectural Society, on Tuesday, January 30, 1838, by William Wallen, Esq., Member.

There are few subjects of inquiry more interesting to the architect, than that relating to the prejudices of its several professors in favour of the adoption of a particular style, to the exclusion of every other. While some are unwilling to allow that the attributes of harmony and beauty are to be found beyond the pale of Grecian art, others as pertinaciously contend, that in the Romans only can we find perfection, whether considered with reference to admirable construction or appropriate decoration. A third class turns a gangrened eye towards the beauties of whatever is still classic, and can only allow of excellence in the creations of a Palladio, a Scamozzi, a Bramante, or a Serlio, who, though reviving the architecture of ancient Rome, appended to it certain features and proportions peculiarly the offspring of their own minds; nor is a fourth class wanting, to whose members the architecture of the middle ages appears decked in all the attributes of grace and elegance in these respects outvying all other styles. The several abettors of such an unwarrantable addition to a particular style, would (with equal reason) declare, that "the rose is a beautiful flower, but as the lily is not *like* the rose, it is ugly." It will be no difficult matter to show that this unhappy perversion has swayed alike the mind of the mere tyro and that of the most consummate master of the art; that it belongs to no particular period—that it results from ignorance of those styles of architecture which are decried, and is injurious to the best interests of the art, while it impedes the progress of the individual professor. The object of this brief essay is to point out some of the inherent beauties of each style of architecture, and to prove that none are deserving of utter condemnation, except when introduced by the mere copyist, who designs without the least regard to historical propriety, and therefore, by the misapplication of the means at his disposal, too frequently brings derision on the style adopted, whereas it should only apply to the incongruous production foisted upon his employers.

It will, doubtless, occur to the minds of many present, that there have been particular attachments in the public mind to certain styles of the art at particular periods. It is natural, indeed, that such should have been the case. At the dissolution of the religious houses, a degree of dislike was entertained for the style in which the architects of the middle ages had erected the various structures appropriated to Roman Catholic worship; and it was very difficult, at this period, to prevent an incongruous admixture of the revived architecture of Rome with the declining Gothic; indeed, the amalgamation of the two styles by contemporary architects was natural, and therefore defensible, although by no means to be imitated.

When the classic style had obtained more serious study, and when the treasures of ancient Rome were disclosed to the eye of the admiring

student, it was natural that the productions of the middle ages should be permitted to dwindle into obscurity; and that when spoken of, they should be spoken of in terms of depreciation. It was, indeed, natural that Roman art should be elevated to the disparagement of every other, when Roman art *alone* was presented to the contemplation of the architectural professor. As yet Grecian architecture was unknown, and Athens (the seat of excellence in the various arts of civilized life) was supposed to have been utterly destroyed, and its architecture for ever lost. No sooner, however, did the productions of Stuart and Revett remove this impression, than a striking change occurred, and to be *Greek*, and *Greek only*, was the aspiration of the tyro and the boast of the titled professor. Once more the Gothic was introduced, nor were those wanting who upheld its thousand excellences; thus has the taste of the public fluctuated from the sixteenth century until the present moment, and when it has not suited it to be Grecian it has been furious Gothic.

Civil architecture must ever be regarded as the handmaiden of history, and the various styles which it embraces are indicative of the habits, the customs, and local necessities of those with whom they originated. As mankind was originally one family, speaking one common language, but being now distributed over the face of the globe, are found to vary in their language and the habitudes of life. So architecture, in its primitive state, was confined to one style, and by the dispersion of the human race, changes and alterations were gradually introduced, as they were called for by the nature of the climate, the customs of the people, or the materials at hand for the purposes of construction or decoration.

The dissimilarity observable in the various styles of architecture (when studied attentively) does not appear more remarkable than that which exists between the form of the rude Hottentot and of the beautiful Gorgian—between the inhabitants of the cheerless regions of the North and that of the genial atmosphere of the South. No architect can be judged able to pass a correct opinion upon the beauties or defects of either the Egyptian, Grecian, Roman, or Gothic style, who has not carefully and maturely studied the history of the several nations from whom their styles have emanated, since the history of architecture constitutes an essential part of the history of mankind.

It is to no purpose that we servilely copy the unfading excellencies of Greece and Italy, whilst our minds remain unimpressed by the local or other circumstances which called them forth,—it is to no purpose that we measure and delineate the ruins of Athens and Rome, unless we are able to trace up to their causes the effects which we see produced—effects which will never be found to have arisen from chance or fortuitous circumstances—clearly proving that there were certain principles acted upon, and that we must become thoroughly acquainted with these principles, ere we can hope to rival that which we admire. Copyism is not imitation, and we can only imitate correctly when the feelings of the original architect have been transferred to our own minds.

No one who is critically acquainted with the various styles of architecture but will accord to each its inherent beauties and defects, which, derived as they are from peculiar local, or other circumstances, should not be unconditionally deprecated or upheld. The Egyptian style, although singularly appropriate in the country in which it was brought to perfection, is (in a great measure) unsuited to our northern climate, and the more when stript of its various hieroglyphic and other ornaments; which, unmeaning as would be their introduction here, were of essential importance in Egypt in denoting the purpose and destination of the buildings to which they ware attached. Scarcely any structure of ancient times is deficient in that most important particular—the appearance of suitableness to its proposed destination; and it is to this circumstance that we must ascribe the revulsion of feeling which is experienced when we see these structures servilely copied, or their decorations introduced where they are wholly inapplicable. We have to lament that in modern times no attention is paid to the destination of our national structures, we erect incongruous masses of brick and stone for our sovereigns—Corinthian palaces for our veterans—structures replete with comfort and convenience for our remorseless criminals, and bastiles for our virtuous and suffering poor!

Of the structures of Egypt it will be unnecessary to speak further; but Egypt does not possess the ruin of a single building which did not originally furnish an adequate reason for its existence, and afford indubitable evidence of a great and scientific people.

It has frequently been asserted that Egypt merely evinced the infancy of Architecture, and that to Greece alone must be ascribed the merit of rendering it worthy the title of a regular science. This assertion comes to us supported by evidence, and in order to discover its fallacy we need but turn to the works of Denon and Desgarnaux, in which, so far as geometry or perspective delineation could convey to the mind a correct idea of the originals, we at once perceive the clearest proofs of scientific arrangement and tasteful and appropriate ornament.

Much praise has been claimed for the Grecian architect, for introducing the Entasis, or swelling of the column, in order to overcome an optical illusion. It is not, perhaps, generally known, that in the monolith or obelisk removed from Luxor to Paris, the same peculiar foresight is observable, nor is it generally known that in the various gigantic figures introduced as bas-reliefs on the structures of Egypt, the parts removed farthest from the eye have been sculptured out of proportion in order to counteract the effect of distance. These circumstances alone will prove that the architectural ruins of Egypt are the production of men of science, and we may add the Hundred Gates, Thebes, the stupendous Enclim of Memphis and Apollonopolis, cannot, even by the most prejudiced, be considered as the offspring of infantile minds.

The simplicity, elegance, and grandeur of the Grecian style are so evident, and force themselves with such power upon the mind, that we must pause, ere we express surprise that practising architects should uphold all that is Grecian as beautiful, "*per se*," just as we should hesitate to condemn the enthusiasm of the amateur, who is ready to admire whatever has proceeded from the pencil of a Raphael, a Rubens or a Titian. And yet there has been and are lapses of beauty and propriety observable in the efforts of the most illustrious of every art, which only shows how important it is to ascertain first principles, and then to form our judgment of the merits of each production by the unerring data which they furnish. It had been well if some of the productions of a Raphael had been unknown beyond the studio; it had been well if the vagaries of a Callecrates and a Ninesicles, had never been incorporated in the eternal marble.

The principal complaint to be urged against those architects who possess the Græco mania, is that they copy and *merely* copy the excellencies before them, without considering the peculiar circumstances which regulated the mind of the original architect. What propriety is there in applying the panathensic procession, attached to the Parthenon at Athens, to a modern club-house, or a park screen; it must be admitted that the application is unwarrantable, and to be lamented (and the more especially in the latter case), as its immediate proxity to the residence of the greatest military hero of modern times, and no less to the statue designed to commemorate his victories, would rather have warranted the representation of some subject connected with the glories of Waterloo, than that of a religious procession designed to commemorate the reverence of the Athenians for the worship of the heathen goddess Minerva.

In speaking of the altered character of the Greek nation, Lord Byron has observed,

> "They have the Pyrrie dance 'tis true,
> But where's the Pyrric phalanx gone?"

Some may say, with truth, that in the productions of the *imitators* of Grecian art, we have the substance presented to us instead of the shadow, and that we nowhere discover the feeling (breathing as it were through the marble) which was infused into the minds of the architects of ancient Greece. No! of this beautiful style we must yet say, "Its country is Greece—its throne the Acropolis of Athens."

But there have not been wanting those who altogether decry the beauty of the Grecian style, and among others, Sir William Chambers unhesitatingly asserts that the Parthenon is much inferior to St. Martin's Church; and as a set off to this assertion of the *first* regius professor of architecture, the gentleman who now holds that important office, has asserted with equal force that St. Martin's is an abortion, that it is neither Grecian nor Roman, but Vitruvian, as distinguished from both, and that Vitruvius himself is a plagiarist and a pretender! What are we to say of such assertions, but that they are the emanations of minds biassed in judgment and closed against the reception of the truth.

The circumstances under which this essay has been prepared preclude the possibility of continuing further remarks to prove that the like unhappy prejudices subsist with respect to the Roman, Italian, and Gothic styles. Inigo Jones, in the *worst taste*, attached a Corinthian portico to old St. Paul's—the work of Gothic architects—simply because he *hated* that style. Such an amalgamation is not more incongruous and repulsive to good taste than the union of the beauteous form of woman to that of a piscatory monster. Again, it may be noticed that Sir C. Wren reviled the Gothic style, and has left us the proof of his utter ignorance of what he condemned, in the unsightly towers of Westminster Abbey, and the ridiculous details of St. Dunstan's in the West, where we have the acanthus leaf foisted upon us in the beautiful and appropriate crocket and terminal of heterogeneous vegetation instead of the graceful finial.

When we see such men as Sir Christopher Wren, Inigo Jones, and Sir W. Chambers, tainted with such unhappy prejudices, and consider that it does not fall to the lot of the architect always to select that style of architecture to which he is personally attached; and that, conse-

quently, where a different style is required, nothing but an intimate acquaintance into that which is selected will enable him to do justice even to his own professional character or meet the expectation of his employers, it must be evidently the duty of the professional man to study each style with care and attention. This can only be done with advantage when every effort is made to render the mind conversant with the history of the people from whom each style has descended to posterity—and this being done, the "ponderous and heavy Egyptian style"—the "tame and feeble Grecian"—the "meretricious Roman"—the "rude Saxon"—the "ponderous Norman," and the "unsightly Gothic," will be terms only found to be used by the ignorant pretender.

THE NECESSITY OF A NATIONAL SCHOOL OF ARCHITECTURE.

Read before the Architectural Society, on Tuesday, February 13th, 1838, by John Blyth, Esq., *Member.*

The interests of architecture are so intimately connected with the qualifications of those who follow it as a profession, and professional qualifications are so much influenced by previous modes of study, and by early prepossessions and prejudices, that I propose in this paper to inquire how far architecture suffers from the want of some methodical and recognised system of instruction preparatory to an individual exercising the important functions of a professional architect;—in other words, I intend to point out the necessity there exists of a British School of Architecture.

In doing this, I am fully aware that I undertake an invidious task, and may probably be considered somewhat presumptuous; but as the main object which I have in view is to impress upon this Society (one of whose professed objects is to originate such a school) the almost universal prevalence in this country of defective training, I trust that my remarks will be received in a spirit of candour and forbearance.

Although it is true we have a Royal Academy, which professes to provide for and maintain a school of architecture, in common with a school of painting and sculpture, I am confident there is no one acquainted with the system and the discipline pursued in that school who would venture to contend that, in a strictly architectural sense, it deserves that name.

There are, indeed, periodical exhibitions and prizes, a tolerable library, and occasional lectures; but as to any superintending care which the Royal Academy exercises over the students, *that* is quite out of the question, and I believe I am justified in stating, that the watchfulness of the council over its school of architecture was so incessant, that for several years together the students were not gratified with either the sight of a professor, or the sound of a lecture.

And even as to the lectures themselves, it cannot be expected they will ever become what a course of lectures on architecture ought strictly to be; that is to say, not merely a history of the origin and progress of the art, and an elucidation of the general principles of design; but a full description of the science of construction, the quality and uses of materials, together with instructions upon geometry and mensuration, and an exposition of architectural jurisprudence as it exists in statues, precedents, and practice.

In the lecture-room of the Royal Academy any such minuteness of particulars would become extremely unpopular. Addressed as the lectures are to a promiscuous auditory of painters, sculptors, engravers, and architects, and having for their main object the illustration of such parts of architecture as may be serviceable to the *collective* assembly, it follows that the historical and decorative branches of the art being those only that may be considered of practical use to the painter and sculptor, the lecturer is under the necessity, from the unfavourable circumstances in which he is placed, of accommodating himself to his audience, of suiting the supply to the demand, and, in short, of rendering his discourses as popular as possible both in their quality and quantity.

They are made, in fact, to be to the painter, what the lectures upon anatomy are designed to be, that is, as much as and no more than is required to serve a special purpose; and from what I know of the architectural lectures (clever as many of them are), I should say, without hesitation, that at the Royal Academy an architect might as well hope to learn the arcana of his art from the lips of the professor of architecture, as a medical pupil would expect at the Academy to acquire an adequate knowledge of anatomy from the eloquent and popular lectures of Mr. Green.

Another great defect to be noticed in the Royal Academy is the want of a suitable museum and gallery, supplied with the best description of models, specimens, casts, and drawings. The science of construction is of the first importance, but in the Academy the student has no guide; practical details form no portion of his studies; his works, not uncommonly, are judged of, not by the real standard of excellence, purity, propriety, and practicability of execution, but by their power of pleasing the fancy. It is thus that young architects, knowing their designs will for the most part be judged of by artists, not unfrequently aim at producing pictorial and picturesque effects, a course wholly incompatible with an attainment to that severe, chaste, and correct style which ought invariably to precede an indulgence in what may be termed the excursive and speculative style.

How shall we otherwise account for the great number of impracticable, incongruous, and clap-trap designs which are not only admitted within the walls of the Academy, but to the exclusion of others of sterling merit—and for the acknowledged fact, that inferior designs have obtained the first prizes which the council had the power of awarding?

Constituted as the council now is, it is too much to hope that matters will materially improve. Composed for the most part of painters, who, proud however as we may be of them as painters, we cannot bring ourselves to believe are competent judges respecting the merits of architectural performances, and the proper rank and claims of architecture, until architects are appointed the sole adjudicators, or altogether a separate school is established, their decisions cannot be relied on, or expected to give general satisfaction.

Inadequate as are the means of the Royal Academy for initiating and grounding young men in the theory and practice of classic architecture, to say nothing of Gothic architecture, which it virtually degrades by an entire exclusion from its system of instruction, it would be unjust to deny it altogether any merit or value; and it would be ungenerous and ungrateful in me, as a quondam student, who, in common with others of this Society, have reaped some advantage from being connected with it, not to acknowledge my obligations. Nor ought it to be concealed, that since the establishment of the Academy, the interests of architecture have been greatly benefited by the taste that has partially been diffused among the people by means of the annual exhibition, and the emulation which it has excited among the junior members of the profession. But as I am now speaking of systems and principles exclusively, truth compels me to affirm, that, as compared with the schools of France and other countries, the Royal Academy falls lamentably short of what a National Institute might become, and ought to be.

In short, the discouraging and rambling way in which architects are now a-days compelled to obtain the qualifications essential to their future success, partly in an office, partly in the Academy, partly in the British Museum, and partly in some society or institute, constitutes a case that calls most loudly for redress.

For what is the result of this state of things? The consequence is, that real merit is either depressed, or remains in obscurity. The public taste continues at a low ebb; the well-stored architect is supplanted by the ignorant and boasting pretender; the profession is humbled, and art is degraded; numerous edifices, which might otherwise have become the means of proclaiming to after ages the wealth, refinement, and magnificence of the nation, will only become the objects of ridicule and contempt.

At present the public are frequently at the mercy of chance, with respect to the qualification of individuals who become appointed architects over important works. The system of advertisement competitions brings into the field a host of adventurers, whose abilities are rarely inquired into, provided they have produced a cheap and gaudy design, and have the name of architect duly inscribed on a brass plate or card.

It not unfrequently happens, in competition concerns, that the architect's estimate, either by artifice or from carelessness, is made to tally exactly with the state of the exchequer. But when the day of trial comes, the lowest tender is found to be half as much again as the sum anticipated. What is to be done under such circumstances? An honourable man would either retreat, in order to do justice to those who were associated with him in the competition, or he would candidly inform his employers that his designs were impracticable below a specific sum. This, however, is a course not frequently taken. The architect has attained his object. He holds the appointment, and intends to retain it. Although he has misled his employers, he now knows their every wish; and it is only for him to pare and shave the walls and timbers of his buildings, and their views may be carried into effect for the sum of money at command.

The process is easy and simple. His two and a half brick walls are reduced to one and a half, with or without piers. It is found that a saving of twenty per cent. may be effected upon the timber and lead work; and as for the foundation, instead of going to the depth his first designs contemplated, it is now discovered that a little rubbish and hot lime, nicknamed concrete, will suit the worst case in point of foundation. Fresh tenders are received; the result is delightful. The whole can be done for the money in hand. The work goes on gaily to the last finishing stroke; every thing wears a promising aspect. The architect, if he should not have entailed a heavy amount of extras, receives his commission, and is dismissed with compliments. Next comes the upholsterer to load the building with furniture, and then the occupants to fill it with company. Up to a certain time nothing serious may be visible; but at length the costly papering, the gilt cornices and painted ceilings, begin to crack. The doors and sashes betray symptoms of disorder. The attic story, in wet weather, is like a dripping well; the floors form segments of circles, and the walls are found to have deviated from the perpendicular. An examination takes place—the murder is out! Our competition architect, for the sake of a temporary advantage, has had the temerity to construct, not by rule, but upon experiment—not upon a medium, but a minimum principle of strength. This is not an imaginary case; and such occurrences will continue to be repeated, until steps are taken by the legislature to promote the study of architecture by proper modes of instruction, and by granting certificates to those only who are qualified in strict accordance with the system that may be adopted. If people were then to persist in holding out a premium upon incompetency, as so many do upon quackery, the odium which now rests upon the profession in general would not be fixed upon the legalized body of architects, but upon ignorant pretenders, and those who should be foolish enough to become the dupes of their artifices and professions.

Competition cannot be too strongly advocated when under the direction of qualified and impartial judges, equally willing and able to give that design the preference which has the most merit. Competitions of this kind are the principal means of eliciting latent talent, and of giving encouragement and scope to younger architects, many of whom from their energy, enthusiasm, and comparative leisure, are pre-eminently qualified to prepare ela-

borate and well-digested compositions. This, however, is a state of things which so rarely happens, that it may be taken much rather for an exception than a rule. Committees and Commissioners, although honourable and well-intentioned, have, for the most part, a task imposed upon them beyond their capacity to execute, when they have to decide upon the respective merits of an architectural design; hence they frequently become the unconscious instrument of mischief and injustice, and the dupes of interlopers who have imposed upon them by the meretricious appliances of colours, landscape, and figures which some artist has executed for them apparently to conceal the deformities of their own part of the performance.

Without presuming to offer an opinion with respect to the question at issue between the Commissioners and those who competed for the honour of superintending the New Houses of Parliament, or without intending to convey the idea that inferior talent was arrayed against Mr. Barry, it cannot, I think, but be a source of satisfaction, that the work is confided to an architect whose intimate acquaintance with the principles of Gothic architecture is a guarantee that his design, when executed, will reflect deserved credit upon himself, and lasting honour upon the nation for whom he has the high and enviable honour of acting.

Under the heap of abuse and contempt which the commissioners have laboured, it is a most fortunate circumstance for them that there are few, if any, who will deny to Mr. Barry the possession of great abilities and competency in his profession. At the same time I think it would have been politic to have allowed the whole of the architects who sent in designs to have expressed their joint opinions by the result of a ballot, and thus the commissioners might have exempted themselves from the charge of partiality and incompetence as judges.

For the purpose of qualifying a youth to be an architect, there are many persons who imagine that nothing more is required than to place him with a professional man. This, however, is a mistake that cannot be too strenuously exposed. The course of study pursued in an architect's office, if that can be denominated study which consists in copying and transcribing, is quite inadequate to the end in view. In order to make myself better understood, I will detail a case or two from every day observation.

A youth enters an office; it may be his master has but little real business; it may be he has much. In the former instance, if he be a competent and conscientious man, he will endeavour to make up to his pupil in theoretic what he is not able to give him in practical instruction; but after all that, the pupil will be but partially and incompletely qualified. Should, however, his master be possessed of neither knowledge nor a sense of duty, the youth will be left to his own resources. The probability is, that his time will be spent in desultory reading and drawing; his acquirements will amount to nothing but a chaos of scraps and fragments; and finding himself incapable of producing anything worthy of notice, a study which, under auspicious circumstances, would have proved delightful and engrossing, becomes at length uninteresting and irksome.

On the other hand, a youth may enter an office in which there is much occupation. Here there is nought but bustle and activity. He copies drawings and specifications of works, and, by good fortune, has the privilege of watching the progress of their execution. Under such circumstances as these there is much to improve, encourage, and stimulate the architectural tyro. But unless hours of patient study in the morning or evening are superadded to those spent in the day-time at office, and in an assiduous application to the writings and designs of the best authors, our student will become little better than a mere mechanical architect. Unless his mind be stored with ideas, and a quick perception of simplicity, harmony, beauty, magnificence, and sublimity; unless the lineaments and features of architectural grandeur and grace are deeply impressed upon his memory, he will have no ready invention, no powers of skilful combination, and we fear but little enthusiasm.

The object of an architect in practice is not to convert his office into a school, but to transact business; not to design imaginary palaces, when he can be employed upon real buildings; in fact, not to build "*in nubibus*," when he can do so on "*terra firma*." Hence it is, that in an office of business there is little time allowed for original efforts, and for the exercise of a student's own faculties of invention.

We observe, further, that there is frequently a difficulty in obtaining a comprehensive knowledge of the different styles of architecture. Many architects have their favourite style, and sometimes to the exclusion of the rest. One gives the preference to Grecian architecture, another to Roman architecture, a third to Gothic architecture, and a fourth to Pictorial architecture. Each aims at practising in that style which he knows he most excels in, and of recommending it whenever and wherever he can. This, in my opinion, is a great evil, and exerts a most pernicious influence upon the rising generation of architects. It tends to create prejudiced opinions; and to establish in the mind a vitiated bias highly injurious to the interests of art.

It was this partial taste which led Sir Christopher Wren to throw discredit upon a style which disgraced not him, but which he disgraced; and the numerous mongrel edifices, which circumstances have thrown in the way of some of our oblique-visioned architects, who, although they condemn a style, do not, for the sake of profit, refuse to burlesque it, attest the baneful consequences of this tyrannical and absurd prejudice.

In some of our architects' offices also, the study of the economic style of architecture has been carried to such an extent, as to set at defiance all the laws of construction; and we fear that public attention will not be awakened to a proper sense of this ill-judged parsimony, till the untimely decay, dilapidation, and downfal of some of our public as well as private works force upon the nation a conviction, that the best and truest economy is to build, in the first instance, under the direction of scientific men, and with a due regard to the solidity and permanence of the structure.

We believe, that even under the most favourable circumstances possible, an architect's office *per se* is not sufficient to qualify for practice. I do not wish to underrate the advantages of an architect's office—in them is to be learnt what elsewhere could never be acquired; and if the best school in Europe was to be formed in this country, I am sure it would not supersede the necessity of office experience; but when we see the mixed character which I have described as prevailing among architects, I think I may safely say, speaking in general terms, that offices of themselves are decidedly inadequate to form a class of accomplished architects; and I might appeal with certainty to every architect in this room, to confirm me in the declaration, that if they had relied for all their information upon the office in which they were respectively placed, and had not been animated by a motive to see and search for themselves, they would not have found themselves fitted to exercise their professional functions with becoming satisfaction or confidence.

It is truly astounding, that the British Government should, not long ago, have interested itself in the formation of an institution, having for its object the interests of architecture, and the protection of the public. But so it is.

Dr. Hogg, in his interesting work, "London as it is," observes—"While in foreign states the government acts as the true guardians of the people, superintending their education, encouraging talent and industry, protecting their health and ministering to their wants and necessities, England, *as a nation*, has comparatively done nothing. The example of France and Prussia has been long before our eyes, but no advantage has been taken of it."

"Many of our national improvements have been promoted more by private individuals than by the Government. The formation of roads and railroads, the construction of docks and canals, the establishment of cemeteries and slaughterhouses; these and other triumphs of science and art, have been achieved without Government (having an annual revenue of fifty millions sterling) contributing one sixpence towards those undertakings; whereas in Germany, France, and other countries, the projectors would have been raised to independence, and ranked among the nobles of the land."

It is the apathy and indifference of the Government and of the Royal Academy to the interests of architecture, which have led to the establishment of the Architectural Society of London in the first instance, and subsequently to that of the Royal Institute of British Architects; and, although we are not so sanguine as to expect that the extensive benefits which they contemplate will be immediately realized, we believe, that in furtherance of a British school of architecture, this Society has been the means of laying a foundation broader and deeper than was ever before laid in this country; —and as the attention of Her Majesty and the nobility has been called to the state of architecture in this country by the Institute of British Architects, we hope, that shortly there will arise a school producing a race of architects, whose names and works shall be as lasting as those of Italy and Greece.

SOCIETY FOR PROMOTING PRACTICAL DESIGN, &c.

Having spoken rather fully of the pamphlet containing an account of its Inaugural Meeting, we shall now be more brief in our mention of this Society than we should otherwise consider it our duty to be. Its aim is most patriotic and praiseworthy, and it is calculated to effect much good both directly and indirectly, and ultimately to raise the taste of the public far beyond its present level. Its efficiency must, however, in a great measure depend upon the readiness of the public to encourage and second its efforts, for the most zealous and spirited individuals will be able to accomplish little if thwarted by the apathy of those to whom they look forward as co operators, in an undertaking which can be carried on successfully only by the diligence and perseverance of many.

At present, as regards our manufacturers and the productions of our artisans, there is no other standard of taste than fashion and expensiveness. By mere accident, the fashion of to-day may happen to be better than usual, but to morrow it may be totally changed for something as bad as ever. Let us look at one species of manufacture which depends entirely upon design and the taste shown in the selection and combination of colours; what can be, for the greater part, more inelegant, or even vulgar, than the papers used for hanging rooms. We are not speaking of exceedingly costly ones, or those which are prepared by professed *decorators*, but of such as are brought into the general market, and used for the rooms of ordinary dwelling houses. However inferior they may be in regard to quality and splendour, they might, without becoming at all more expensive, be in infinitely better taste, so as always to be pleasing to the eye, after they had ceased to be in the very latest fashion. On the other, as a striking proof that very great improvement of appearance has been actually effected of late years without any increase of price, we have only to point to the embellished wrappers of many publications which are brought out in parts, or sold done up in thin covers. Although they are designed to be merely temporary, the borders, vignettes, and other decorations on some of these are in a style that some years back, when a mere piece of blue paper was thought quite sufficient for the same purpose, would have been considered prodigies as specimens of such embellishments, perhaps very prodigal also. There is no reason why similar improvement should not take place in every other production of industry and manufacture, and we hope that all obstacles in the way of such improvement will be speedily removed. At all events, the Society will do what they can to promote the kind of improvement so greatly to be desired; it remains for the public to determine whether their meritorious efforts shall be crowned with success.

OBSERVATIONS ON LOCOMOTIVE AND STATIONARY ENGINES.

Remarks on the Report of Messrs. Stephenson and G. P. Bidder to the London Grand Junction Railway Company.

By an Old Engineer.

Sir,—I perceive that Messrs. Stephenson and Bidder, have, in a report to the directors of the London Grand Junction Railway Company, recommended the same mode of working that line, which they had advised in the case of the Blackwall Railway. This system is in my opinion, so utterly absurd and ill advised, that, in a desire to avert from the shareholders and the public the consequences of this most rash project, I request the insertion of a second letter on this subject in your Journal.

Messrs. Stephenson and Bidder still recommend the *tail* rope in preference to the endless rope, and their reasons for so doing are thus explained :—

"We would also remark, that the application of stationary engines to your line of railway can hardly be considered an experiment, as on the London and Birmingham Railway the rope is nearly as long as it will require to be on your own line; for although the carriages are drawn by the stationary engines only one mile on the former, yet, being attached to an endless rope, instead of a tail rope (as would be the case on the London Grand Junction Railway), the rope is necessarily two miles long, whereas the ropes proposed to be adopted on your railway are only two miles and a half long, being half a mile longer, which difference is compensated by your line being straighter, and not having inclinations so steep as on the Euston Square extension."

It must be borne in mind that this paragraph has allusion to the double line of rails, each of which lines, according to the terms of the report, are to be kept in action, in order to start the trains every quarter of an hour from each end; so that for the purpose of working the line, a rope four times the length of the line, ten miles long, must be kept in motion; thus making the length of active rope exactly the same as if it were an endless rope, or five miles long, and the two tail ropes will be each two miles and a half, or five miles jointly. The rope between the train and engine must be coiled up, or around a drum or cylinder, as the train advances, and the tail must unwind at the same rate; and, unless some provision is made to meet the difficulty, the rope coiling over itself will increase the leverage upon the engine. If the line was made to slope towards each terminus, a compensation might thus be made in favour of the engine as the rope coils upon the cylinder, and this would meet the case both ways; but this does not coincide with the principles laid down, for the gradients to follow the line of the soil. The only method left will be some mechanical arrangement in the gearing connected with the engines, which will be necessarily complex in itself, and matter of much cost in the first instance. It is therefore evident that a just view has not been taken of this point of the subject, for had an endless rope been employed, it would only have been necessary that it should have been double the length of the line, or five miles long for two lines of rails, whereas, by the tail rope being used in preference, it must be necessarily double the length, as observed above. Thus there is a double friction in the uncoiling of the tail over two loose pullies, instead of one, as in the case of the endless rope. The credit, therefore, for economy, in this instance, is placed to the wrong side of the account.

I observe, in corroboration of my view of the case, expressed in my former letter, that Messrs. Stephenson and Bidder admit the fewer the stations the better for their system; but the fact is, unless they adopt a higher velocity than that proposed in their report (twenty miles per hour), they cannot, with even one station, accomplish the distance in the time they propose. Twenty miles per hour is one mile in three minutes; two miles and a half will, therefore, occupy seven minutes and a half; allowing, then, one minute and a half for gaining and losing the velocity at each terminus, is nine minutes, one minute and a half at King's Cross, for stopping and starting the velocity, and one minute for taking up and putting down passengers, will be eleven minutes and a half; then, unless the maximum velocity be increased to thirty-seven miles and a half per hour, or 1.6 miles per minute, the object cannot be effected, of performing the entire journey in eight minutes, because the loss of four minutes must in all cases take place; and, in fact, increases proportionally as the maximum velocity is increased.

It is made matter of congratulation, "that the traffic is more regular, and does not come in such gluts as may be expected upon the Blackwall line; consequently the trains will be more equalised, and more uniform in load." But, with a view to economy of construction, they destroy the levels and follow the line of the soil, leaving just headway enough to cover the regulations for crossing the streets, converting the line into a series of undulations, and thus making the load upon the engine a matter of perpetual variation; at one moment being required to drag the train up an excessive inclination, and at another, the train will plunge down a corresponding inclination, requiring the utmost exertion of the brake to prevent its attaining a dangerous velocity; and then the surge which will take place when the power of the engine, at the top of its speed, is again applied to the train, will be such as very likely to snap the rope, and will produce such a shock as will be, in the worst sense of the word, offensive to the passengers.

The observation is very true, that the shorter the line, the better adapted for the application of their system; but for the purpose of rapid locomotion, every line is too long, to which it would be possible without objection to apply the stationary engine system in a mechanical sense; but the defects of the system, as a dangerous one, are such, that it ought to be made, in my opinion, for the purposes of a passenger traffic, a case of utter prohibition.

The gradients of the Birmingham line average sixteen feet per mile; so that the gradient upon this line being only fifteen feet per mile, are more favourable for locomotive than upon the former line, excepting a short gradient of nineteen feet, which would not affect an engine coming upon it with velocity, more particularly as this line would be, for the most part, a passenger line, and the trains light.

I think I clearly proved, in my former letter, that, for all the purposes of a railway, the locomotive is more under command, susceptible to a higher degree of adaptation to the curves, beyond comparison safer, and for the purpose of drawing up accurately to the intermediate stations, no comparison is admissible. How do Messrs. Stephenson and Bidder provide for the case of the engineer missing his mark—by a few turns of the great cylinder, which would make a difference of perhaps 100 yards or more in the point of the trains stopping? How are the passengers at the station at King's Cross to adapt their individual velocity to this accident? Are the old ladies and the fat gentlemen to run for it, or wait for a better hit next time. This would never happen with the locomotive, for it draws up to a point with as much precision as a stage coach.

Account is taken for the London fogs to form an argument in favour of their system; this, indeed, gives a foggy character to their view of the case; it is a well known fact, that an engine always gets through its work better upon a wet day than a dry one, provided the rails are not muddy, as they never can be upon a viaduct; it is true, the wheels skid more, but what is lost in the adhesion of the wheels of the engine is very much more than counter balanced in the reduced friction in the wheels of the carriages. This is a fact so well known to every engine driver, that I am astonished Messrs. Stephenson and Bidder have ventured the statement, unless they calculate upon the heads of the directors being so foggy, that any argument, however *slippery*, will pass without being called in question.

The estimate of cost for the stationary engines is limited to one engine at each end of the line, whereas it is found, upon the Liverpool line, and upon the Birmingham line, essential that there should be provided duplicate engines as a provision against accidents; where, then, is the justice of the comparative estimates in this case?

The nuisance of ashes, &c., from a locomotive (if any exist), is chargeable, as stated in my former letter, to misarrangement; the pullies, supposing them to be eighteen inches in diameter (larger than those upon the Birmingham line), when the rope is travelling at the rate of twenty miles per hour, will revolve 370 times per minute; I therefore allow this fact to speak for itself, as regards the quietness of the system.

In the case of the locomotive system, if it be required, on account of a sudden increase of traffic, to increase the means of transport, it is only necessary to place upon the line more locomotives and carriages, these travelling at the same velocity as upon other occasions; and then the expense of engines, &c., and the consumption of fuel, is proportional with the traffic, and paid for by the occasion calling it forth; and when not needed, the engines are idle and non consumers; but in the stationary engine, Messrs. Stephenson and Bidder admit, to meet such a demand, which may perhaps only occur upon some fair or holyday once or twice during the year, they would need more powerful engines, which must consequently, upon every other excepting extreme occasions, work at a loss; and they can only meet the demand by an increase of velocity in the train itself, to perform the distance in eight minutes; I have shown it will be necessary to employ an average velocity of thirty-seven miles and a half per hour; how ridiculous to say that they will, in the case of the traffic doubling, which may be expected on Sundays, that they will produce a velocity of double, or seventy five miles per hour; and the case is no better if they double the load, for then during the week they will be throwing away half the power of their engines.

The suggestion of a single line of rails comes in very well as a last argument, for it is so very thin in reason, that for such a line the directors themselves must perceive it to be perfectly visionary.

It is a fact generally known, that the Whitstable and Canterbury Railway, of *five* miles long, worked by fixed engines, has been let to contractors who are about abolishing all the engines upon the line, excepting one, and to substitute locomotives. This railway was made by Mr. George Stephenson, and the average time for performing the journey *now*, is forty minutes. It is to be hoped, therefore, that his experience has been since so far improved as to insure to the directors of the Grand Junction Railway there shall be no mistake *this time*.

The discussion instituted by the directors of the Liverpool and Manchester Railway Company, to determine which system of working their line was most eligible, has supplied a valuable body of evidence in the reports of Messrs. Walker and Rastrick, and subsequently of Messrs. Stephenson and Locke. These reports are given at length in Wood's "Treatise on Railroads," to which work I refer the reader; but the following extract, giving the estimate of Messrs. Stephenson and Locke, being most important, I must introduce here :—

LOCOMOTIVE ENGINES.

The power of each engine is taken as equal to 20 tons of goods, or 30 tons gross, conveyed 90 miles, or three trips between the two places daily = 1800 tons conveyed 1 mile, at the rate of 12 miles an hour. Engine weighing under 5 tons.

Cost of one engine and tender	£600
One-fifth for spare engines and tender . . .	120
Total cost	£720

	£	s.	d.
Interest of capital, including depreciation of 720*l*., at 7½ per cent.	£54	0	0
Add annual repairs, as ascertained by actual observation on the Springwell and Darlington Railways	50	0	0
Engine man, wages 21s. per week, assistant 26*l*. per annum	80	12	0
Coals for fuel, 439 tons per annum, at 5s. 10d.	128	0	0
Grease, oil, hemp, &c.	12	0	0
Total cost of one engine, working 312 days	£324	12	0

	£	s.	d.
Each engine being calculated to take 20 tons of goods 90 miles, or 1800 tons 1 mile, and the daily traffic being estimated at 4000 tons conveyed 30 miles, or 120,000 tons 1 mile, will require 67 engines to perform the work at 324*l*. 12s. 10d. per annum, is	£21,750	19	10
Messrs. Stephenson and Locke estimate that locomotive engines are capable of conveying goods up the inclined planes, which they propose to do by assistant engines, which will perform $\frac{1}{10}$ths of the work on a level = 12 tons, and supposing each engine to make 20 journeys, or 60 miles a day, will be 216 tons. Hence $\frac{4000 \times 12}{20 \times 240}$ = 10 assistant engines, at 324*l*. 12s. 10d.	3,246	8	4
Annual cost of five water stations, at 104*l*. each	520	0	0
	£25,517	8	2

Interest of capital, and annual expenditure of locomotive engines, which, for 4000 tons, conveyed 30 miles per day, is equal to 0·164 of a penny per ton per mile.

AMOUNT OF CAPITAL FOR LOCOMOTIVE ENGINES.

	£	s.	d.
Ninety-three engines and tenders, at 600*l*.	55,800	0	0
Four water stations, at 500*l*.	2,000	0	0
Crossings at the Rainhill and Sutton inclined planes, for the assistant engines to pass from one line of road to the other	200	0	0
Total capital for locomotive engines	£58,000	0	0

STATIONARY ENGINES.

Dividing the distance into the same number of stages as Messrs. Walker and Rastrick, the following is the power calculated by Messrs. Stephenson and Locke :—

			Horse power.
One 40	horse power engine	at the tunnel	40
Three 80	ditto	on the 1½ stages, to the foot of the Rainhill plane	240
Two 50	ditto	at the foot of the two planes	100
One 48	ditto	on the level between the planes	48
Two 80	ditto	to work the two planes	160
Twelve 80	ditto	between the foot of the Sutton plane and Manchester	960
One 24	ditto	at Manchester	24
		Total horses power	1572

ESTIMATE OF THE EXPENSE OF STATIONARY ENGINES.

	£	s.	d.
One engine of 40 horse power at the tunnel	£1,800	0	0
Seventeen stations, including the two planes, with two 40 horse power each, at 4,200*l*.	71,400	0	0
Two stations at the bottom of the two planes, with two 25 horse power each, at 2,880*l*.	5,760	0	0
One station on top of planes, with two 24 horse engines, same as above	2,880	0	0
One 24 horse power engine at Manchester	1,890	0	0
Sheaves for ropes, 13,090 at 12s. each	7,854	0	0
Four sets of crossings, and turn outs at each station, 88 at 50*l*.	4,400	0	0
	£95,984	0	0

	£	s.	d.
Interest and depreciation of capital, 95,984*l*. at 6½ per cent.	6,238	19	2
Coals for engines, repairs, and working expenses	18,917	0	0
Ropes	16,136	7	10
Duplicate ropes, interest of value upon	739	4	5
Interest of capital, and annual expenditure of stationary engines	42,031	16	5

which for 4000 tons, conveyed 30 miles per day, for 312 days, is equal to 0.2694 of a penny per ton per mile.

AMOUNT OF CAPITAL FOR STATIONARY ENGINES.

	£	s.	d.
Estimated capital as before	£95,984	0	0
Ropes, &c. in use	10,727	18	0
Duplicate ropes and machinery	14,784	9	0
Capital requisite for stationary engines	£121,496	7	0

COMPARISON OF THE TWO SYSTEMS.

	Capital.			Annual expense.			Expense of taking a ton of goods one mile.
Locomotive Engines	£58,000	0	0	25,517	8	2	0.164 of a penny.
Stationary Engines	121,496	7	0	42,031	16	5	0.269
	£63,496	7	0	16,514	8	3	0.105
Locomotive System	Less.			Less.			Less.

We trust we have given a brief, and, at the same time, sufficiently explanatory account of the estimates of the two systems; and shall, therefore, leave it to the reader to draw his own conclusions. We are the more inclined to do this, from having, in 1822, advocated the superiority of the locomotive over the stationary system; and, therefore, any observations of ours might be deemed as coming from one predisposed to judge in favour of the former system.

With regard to the policy of employing one or other of these modes upon public lines of Railway, we must, however, in candour,—and we think so much due to our readers,—state, that we entirely concur with Messrs. Stephenson and Locke in opinion, "That in considering the long chain of connected power of the stationary engines, given out by so many machines, with the continual crossings of the trains from one line to the other, and subject to the government of no fewer than 150 men, whose individual attention is all requisite to preserve the communication between two of the most important towns in the kingdom, we cannot but express our decided conviction, that a system which necessarily involves, by a single accident, the stoppages of the whole, is totally unfitted for a public railway.—*Wood's Treatise on Railroads.*

This estimate, if any faith is to be placed in estimates at all, is conclusive against Messrs. Stephenson and Bidder.

I remember, in my boyish days, Mr. Bidder, who was well known as a calculating prodigy, being asked many difficult questions of arithmetic, which took myself and others some time to resolve, he stated in much less time; but when he explained the process by which he arrived at the result, it was found such, that no person would think of adopting; and it was only admissible in his case, because he knew no other method. A faculty for arithmetical calculation, and that for mechanical combination, are widely different; in the first, and Mr. Bidder's case, any method, however round about, is good, provided it gives the true solution of the question, and no permanent interests are affected by the result; but a mechanical combination can only be properly carried out by comparison with every other known and possible method to accomplish the same object. Judgment, is the grand characteristic of the mind of a great engineer, which decides between various systems, and adopts the best. It is necessary that an engineer charged with the responsibility of a great undertaking should be endowed with a mind superior to every little feeling, that he should be above patronising one system above another, excepting upon the grounds of its own merits. Ingenuity apart from discretion is more frequently mischievous than otherwise, and it is only when the imagination is held in perfect keeping by the judgment, that it ought to be trusted, particularly in cases such as these, where the property and interests of others is at stake.

Mr. Crawshay, at the general meeting of the Blackwall Railway Company, stated his experience, from his own books, of the superiority of the stationary over the locomotive engine system. The only experience Mr. Crawshay can have had upon this subject must have been in connexion with his collieries or mines, where the only carriages travelling upon his railway are coal waggons. A railway for a colliery, where the velocity is from eight to ten miles per hour, and a railway for passengers, where the velocity is twenty to thirty miles per hour, are two very different things. In the first case, the rails may be laid any how, a few jolts more or less matters not to the material carried over the line; and if a locomotive were employed, it would be very soon jolted to pieces; therefore, in this case, a fixed engine, subject to none of the shocks of the locomotive, is decidedly better, the road may be allowed to run more into neglect, and the working expense will be reduced. But in the second case, if the rails are laid in the permanent manner, essential for the convenience of the passengers, the line will be then in a state to allow of the locomotive to work upon it *at an equal advantage*, with the fixed engine; the expense of keeping the line in trim, is called for as much by the passengers as by the engine; and if it is adjusted for the one, it ought not to be wholly charged upon the other. Messrs. Stephenson and Bidder ought, therefore, in common justice, to have set this gentleman right upon this point; I have made many inquiries, but have been uniformly assured, that beyond the mere report, *no plan* of the system has been furnished by Messrs. Stephenson and Bidder to any of the parties who have adopted their suggestions. I confess I am astonished at this, that men of business should commit themselves to such a degree as to patronise a plan of which they know nothing, of which the projectors do not even offer a tangible explanation, is astonishing. I earnestly recommend all those parties interested in this discussion, to require from Messrs. Stephenson and Bidder such proofs of their methods before carrying them into effect, that they may be exonerated of the responsibility of having involved the property of their constituents in a project, which, I feel most strongly, will prove a hopeless and utter failure.

AN OLD ENGINEER.

THE WINTER PALACE, ST. PETERSBURGH.

Among the destructive fires which have occurred within the few last months, that which has consumed the Winter Palace at St. Petersburgh, and threatened also to sweep away the contiguous edifice distinguished by the name of the Hermitage, is the one which has committed the most serious and extensive devastation. This will be apparent from the description given of that extensive structure by Dr. Granville, in his work on "St. Petersburgh," which we here lay before our readers in an abridged form, and from which it will be seen that the imperial residence occupied a site upwards of ten times greater than that of our Royal Exchange.

"This great and imposing structure has a square form, three sides of which are unconnected with any other building. The north side, or that which presents its front to the Neva, is 721 feet in extent, one fourth of which line, at each extremity, projects 24 feet from the centre. It is composed of a basement story of the Ionic order, surmounted by a principal, and a second story or attic of the Corinthian order. The roof is surrounded by a light balustrade adorned with vases and statues. The Corinthian columns and pilasters placed between the windows of the principal and second story, twenty-six of which are single and six double, are thirty-five feet high. The upper entablature is interrupted in the centre and the two extremities by appropriate pediments. This may be considered as the principal, and certainly the finest elevation of the building. The granite quay in front, separating it from the river, is wider here than in any other place. The style of the Winter Palace would be called heavy, were it not that so great a mass of building requires, perhaps, less of that airiness which becomes edifices of smaller dimensions. Its architect, Rastrelli, who owed his subsequent elevation to the dignity of count to the erection of this structure belonged to that school which loved to pile one upon another the more majestic orders of architecture, frequently injuring their effect by the introduction of ornamented architraves, flower festoons, and arabesque carvings, with pediments over the windows, formed of disjointed cornices terminating in scrolls. In these extravagant designs, Rastrelli followed the perverted taste of his day. Still, as a mass, the Winter Palace is more striking than either the Tuileries, the Royal Castle at Berlin, or any of the royal palaces I have seen in Europe, excepting that at Madrid, which, though smaller, has a more imposing front. For size, the Winter Palace I believe to be superior to all these, and in internal decoration it yields to none of them.

"The great or parade staircase, which leads from the basement to the principal story by a flight of marble steps, is remarkable for its magnificence, and the grandeur of its architecture. It would be an endless task to attempt a description of the different apartments of this Palace, which occupies an area of 400,000 square feet. There are from 90 to 100 rooms, forming almost a labyrinth, through which it requires great practice to proceed. The great Banquetting Room, the Hall of St. George, and the Salle Blanche, are amongst the most striking:—the first is 180 feet by 100, lofty, and incrusted by some of the finest marble, having a row of columns at each end, and the sides decorated with attached columns of the same material; adjoining to this Banquetting Hall, is a smaller one 100 feet by 110. The Great Hall of St. George is one of the most magnificent rooms on the continent,—neither the Tuileries nor the Palace at Versailles can boast of anything like it; it is a parallelogram, 140 feet by 60, surrounded by forty fluted Corinthian columns of porphyritic marble, ranged two and two, on which rests a gallery with a gilt bronze balustrade of exquisite workmanship. The capitals also and bases are of gilt bronze.

"The Salle Blanche is nearly the same dimensions as the Hall of St. George, and runs at right angles with it, though not immediately adjoining to it; but, as its name denotes, all its decorations are white."

Mr. Rae Wilson, also, in his account of this palace, observes, "The Hall of St. George, or audience chamber for the reception of foreign ambassadors, is truly magnificent, and has a throne with a flight of eight steps leading up to it, above which are the Russian arms, superbly embroidered." The same writer concludes his description by saying, "Some idea may be entertained of the magnitude of this gorgeous palace, when it is stated that it contains about 1,000 inmates, and in the stables 2,500 horses, 584 grooms and assistants, and 600 carriages."

WHITE'S PATENT RAILWAY LINK.

Sir,—The accompanying diagrams represent a portion of a patent which I have obtained for certain improvements in the construction of railways. It consists in the application of a retaining link, to prevent the ends of the rails from separating.

Fig. 1. Fig. 2 Fig. 3.

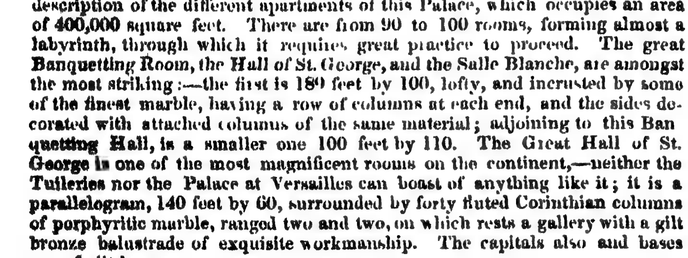


Fig. 1 is a side view of two pieces of rails as they meet in the joint chair, and shewing the retaining link in its place. Fig. 2 is a section of one of the pieces, taken through a hole which is drilled to receive one of the pins projecting from the link. The holes so formed in the ends of the rails are a little larger in diameter than the diameter of the pins, and their difference make provision for the expansion and contraction of the rails, but admit of no farther separation.

Fig. 3 is a view of the link, showing the position of the pins. The diagrams are drawn to a scale of two inches to a foot, and the transverse section, fig. 2, is a correct sketch of the 75lbs. rails which is used upon the London and Birmingham Railway.

Upon the Liverpool and Manchester Railway I have measured, in some places, rails of this description, separated in the joint chair to the extent of an inch and a quarter. Probably, when the wedges are loose, the traction of the wheels drive them backwards, as the carriages progress forward. But whatever be the cause, such gaps exist, to the serious deterioration of the engines and carriages which run upon the railway. Yours, &c.

7, Pratt Street, Lambeth, JAMES WHITE.
Feb. 20, 1838.

PRESERVING TIMBER.

A patent has recently been taken out for this purpose in America. The following is an extract from the specification, as given in the *Franklin Journal*.—

I take (says the patentee) a quantity of tar (either Stockholm, Archangel, or American), which I submit to the process of distillation, and the apparatus, or still, which I use for this purpose, is similar to what is called a pitch still, which is made of copper, and well known, and forms no part of my invention, nor does the process of distillation, for separating the essential oil from tar, which is effected in the manner following:—The still which I use will contain about 400 gallons, but I do not put into it more than three quarters of that quantity of tar, or twelve barrels, of the usual size, of either of the kinds before mentioned. The first product will be the acid of the tar, bringing with it a light coloured essential oil, which separates immediately and floats upon the surface of the acid in the receiver, which I *prefer of wood* (a cask with one head, furnished with a cock for the withdrawing the acid from below, being applicable to the purpose), after some time the acid will cease, and the essential oil will come over in a very considerable stream, which I collect from the receiver, to the extent of about four gallons to the barrel, or forty eight gallons in the whole, including that which came over in the first instance with the acid; the fire is then to be withdrawn, and the contents of the still, which by the extraction of the essential oil has become *pitch*, allowed to remain *in the still* until the following morning to cool, then it may be let off by means of a pipe fitted with a brass or iron plug, into a large receiver of cast iron, or other suitable material, and finally put into casks for sale.

I will now proceed to describe the combining of the essential oil with the other materials for the making of my "Metallic Solution." To effect this, I place *two* or more large casks upright, removing the upper head of each, and throw into them well rusted iron hoops, or tin cuttings. I then pump into them 100 gallons or more of the essential oil of tar, before described, completely covering the metal. This oil I cause to be repeatedly pumped every day from one cask to the other for about six weeks, by which time the oil will have become very black and much increased in gravity, whilst the iron hoops or tin cuttings will appear quite bright, and free from oxide.

They are then to be taken out and piled up in an open space of ground and set fire to, for the purpose of burning off the oil, and afterwards laid by for reoxidation, which may be much facilitated by pouring over them a weak solution of common salt and water; when they have again become rusted they are fit for use.

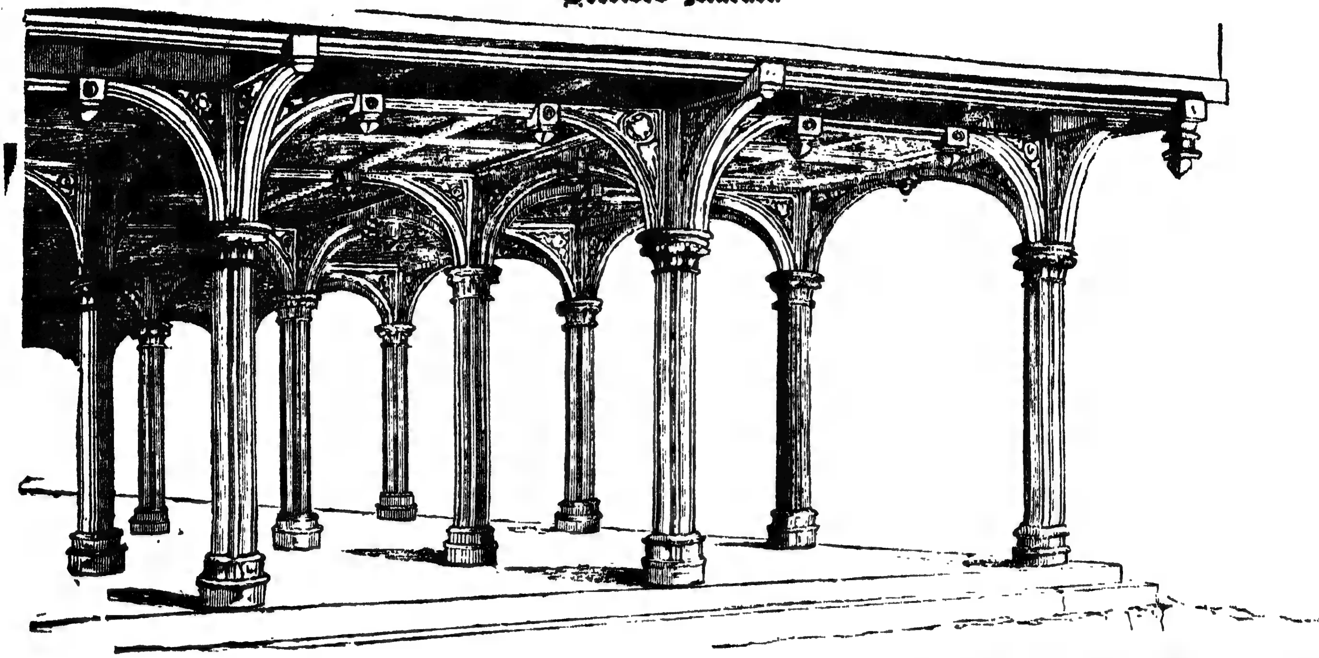
I will now proceed to describe the method I pursue in saturating timber and wood with the metallic oxide.

For saturating piles *already* driven into the sea, forming jetties, or piers, I cause an inch augur to be passed down the centre of the piles to the bottom end, if possible, or as far down as can conveniently be done, and "liquid oxide" poured down the hole until filled. This is to be repeated as often as may be thought necessary, but generally in two or three days it will be found oozing through the pores of the wood, depositing the incrustation of *iron*, which, in combination with the *essential oil* of the *tar*, resists alike the action of the water, and the attacks of the worm. A wooden plug or tree nail is then to be driven fast into the hole, which may be removed by the auger at any time for the purpose of giving the piles a fresh supply. This method is likewise applicable to the timber used in blocking streets, the woodwork on railways, and to all wood subject to damp or moisture, or the attacks of worms or other vermin. For out door buildings liable to dry rot, it may be used cold in the usual way of varnish or tar, with a brush; for being perfectly liquid, it penetrates most rapidly, drying completely in eight or ten hours, when a second dose may be given. Paint applied afterwards dries quickly, but for most purposes two or three applications of the preparation render any other coating unnecessary; for as soon as the pores of the wood become filled, it assumes the appearance of varnish.

Patent Pump.—We have witnessed the double action horizontal pump in operation at the Trades' Lane Calendering Company's premises, and were fully satisfied of its superiority over every kind of pump hitherto in use. It threw out a copious stream of water, without any intermission between the strokes, and without the friction of an ordinary pump. Its chief excellence, we think, is shown when converted into a fire-engine, with a leather attached to it for raising the water. When employed in this way, with two men working at the handles of the pump, a column of water was raised to the height of forty or fifty feet, scarcely inferior in size or force to that discharged by an ordinary fire-engine wrought by a dozen of men. We are convinced that the superiority of this invention cannot fail to bring it into general use.—*Dundee Courier.*

THE ANTIQUARIAN. No. 1.

Hereford Market.



Amongst the various subjects of a purely mundane character which excite the attention of thinking men, there are few which present a more varied, entertaining, and useful field for inquiry, than is to be found in the progress and vicissitudes of the arts of design. In the expression and form bestowed upon matter by the tutored hand of man, we see the fullest development given to his intellectual faculties, and the formation of a mute, yet eloquent language, affording us most palpable and unerring evidence of the peculiarities of thought and feeling, which have characterized periods enlivened by mental activity. The practice of the arts of design proclaim one of the great triumphs of man's existence on earth. It presents an ever-varying language of distinctly his own creating, placing him infinitely above all created things, and manifesting the divinity of his nature.

In viewing his formation, we are struck with the marvellous alliance existing between the hand and the mind, and feel convinced that the dignity of human nature is never more fully exemplified than when the admirable mechanism of the former is engaged in giving birth to the ingenious and graceful conceptions of the latter. When his faculties are thus employed, man appears in the graceful light of Nature's willing associate, engaging in her favourite scheme of adorning the earth.

This power of creating and imitating objects is one of the great prerogatives of man; and beauty being the principle which first rivets his looks on Nature, leading him subsequently to the enjoyment of her vast stores of treasure, and exalting and refining the speculations of the mind, nothing seems so natural than that he should seek to incorporate into his own works an element which exerts so vast and beneficial an influence over his existence; hence it is that nations, down to the most savage, have endeavoured to give *beauty* to their productions, thus paying tacit, yet unequivocal homage, to the grateful sway exerted by that quality over the mind in its mute but continual converse with external objects.

Of all nations who have thus hearkened to the voice of Nature, the first to interpret it with fidelity, and who have hitherto surpassed all others in that vocation, are the Greeks, whose devotion to the principle of visible beauty, engaged them in a profounded study of its laws, the essence of which they traced home to its sanctuary, the human form. It is now our fortune to be conversant with their works, may we learn to equal them, which we shall do, if a conviction of their beauty lead us to tarry at the source whence its authors drew forth their inspiration!

Although our ancestors have fallen short of the Greeks in the cultivation of the arts of design, still have they so improved those opportunities which were offered to them, and so fostered the styles which from time to time they were made acquainted with, as to render the study of their productions a source of interest and delight to the British antiquary.

Our attention is at once engaged by the complete harmony which characterizes the style in which they are composed, and the sane mode displayed in the development of the thought itself. This teaches us an important lesson; it shows that our artists of by-gone times studied Nature too, and prized the unity which reigns throughout her works. A very high degree of beauty results from their appreciation of that important element in design. This beauty is increased by the admirable adaptation of each and every part of these buildings to the purpose for which they were originally designed. The ornaments bestowed upon them, and by no niggard hand, are generally characteristic, revealing circumstances connected with the epoch, as well as the intention of their authors.

Thus thoughtfully conceived and executed, these buildings embody intellect which sheds light over the times which gave them birth. When, too, we bear in mind the sublime internal effects of many of the more important edifices, called into existence by religious devotion; the mathematical skill their construction displays; the thorough acquaintance with the resources of art, based upon an observation of the mysterious variety of nature, which these buildings exhibit, from the most important to those of least pretension, as is most clearly shown in the ingenuity with which corresponding parts are varied in the detail, without the least detraction from their uniformity of appearance; the profusion of ornament—degraded, it is true, at times by woful caricature and intentional deformity, but still evincing an untiring invention, which nought, save the love of Harmony, could control; the spirited and delicate execution of these ornaments, and every where the excessive finish they discover; the shrewd contrivances, and appreciation of optical effect, affording unequivocal proofs of the taste and intelligence of our ancestors, and of genius on their part in no way inferior to that of the artists of antiquity, wanting only their more chaste conception of style to have led to equally high results;—when to this we add the active agency of these remains, in recalling and elucidating by-gone events, frequently of the highest import to the living, their influence in imparting life and interest to the associations which they give rise to in the mind; that, in short, they stand as it were as beacons strewed over the land, guiding the imagination in its excursions into the past, it will be confessed that few subjects offer to the enlightened Englishman a more varied, entertaining, and useful field for inquiry, and that his interest and pledge for the discharge of a sacred duty are at stake, in the preservation of the antiquities of his country.

Hereford Town Hall and Market.

We have been guided in our selection of this subject, for the first number of the Antiquary, for the sake of giving an ancient building, which should combine utility in its design, taste in its decoration, and skill and ingenuity in its construction.

This hall is one of the masterly performances of the age of James the First, and is considered by Price to be the work of the famous John Abel, who many years afterwards rendered such signal services when Hereford was besieged by the Scots. The same author says

that "of all the buildings in Hereford, of a decidedly useful character, the Shire Hall is the most worthy of notice." This building, which occupies the centre of the Market Place, is in the form of a parallelogram, and consists of two stories; the lower, composed of twenty-seven Gothic stone pillars, with raised bases, and carved decorated capitals, supporting a timber framing; the upper (not given in the view) being entirely of timber, and projecting beyond the outer range of columns beneath. This projection gave rise to the necessity of brackets, which are so simply and ingeniously contrived, as to form a very graceful portion of the design.

The upper story has been lowered and much altered, from a fear that the columns had too great a weight to sustain; it was originally distributed into apartments, for the use of the different trading companies of Hereford. The portion thus altered was originally designed in harmony with the rest, and was always considered a most ingenious work, which we can the more easily believe from the merit of the remaining part. This part, intended for the business of a market, answers its end admirably; the overhanging portion increasing the shelter, and the slender points of support admitting abundance of light; the wear and tear incidental to a market, is counteracted by the harder material of which the columns are formed.

We are struck with the intelligent union of the two materials, stone and timber, in which the former displays itself as contributing to the support of the building, the latter as the means of combining the elegancies of art with the requisites of construction. Ornament, both characteristic and graceful in its composition, forms a prominent feature in this useful building, plainly showing that our former artists entertained that famous maxim of the Greeks of old, that a thing to be good, must, to its other qualifications, unite the beautiful.

Finally, we may observe, that viewed either as a Work of utility, or as a specimen of art, Hereford Market is well worthy of the attention of the architect and amateur. A. W. H.

LONDON AND BIRMINGHAM RAILWAY.

Mr. R. Stephenson's Report to the Directors.

February 17th, 1838.

"In reporting on the present state of the works on the line, and our prospects as to future openings, it will not be necessary to treat in detail of that portion between London and Tring which is already open to the public, nor to mention specially the quantities of fencing, brickwork, &c., which remain to be done on each contract as stated in the estimates already delivered, such works being comparatively unimportant, and not likely to interfere in any way with the opening of the line. It may, however, be stated with reference to that portion between London and Tring, that the permanent road is in tolerably good order, except on the Brent embankment, near London, and on the Colne embankment, near Watford. Both these works have continued to subside, with scarcely any intermission, more or less rapidly since their formation; the former from the slippery nature of the material which composes it, the latter from the unsoundness of its substratum in the valley of the Colne. The gradual subsidence of embankments admits of no other remedy than maintaining the level of the railway by the constant supply of new sound material adapted for ballasting, which, in the present case, may fortunately be obtained from a convenient spot, and at a moderate expense, for there is, in the Company's possession at the south end of the Watford Tunnel, a large store of excellent gravel and chalk, sufficient to meet all the demands of the line and stations between Watford and London for some years.

"The only other points between London and Tring which call for remark, are the Boxmoor embankment, and some portions of the Aldbury contract, where we found it very difficult at first to keep the rails in working order; but they are now in much better condition, and will continue to improve rapidly during the ensuing spring and summer. By this period we may expect that all the embankments will become so consolidated, as to admit of the engines working over them without any necessity of reducing the speed below the proposed average speeds to be adopted with the passenger trains.

"*Tring Contract.*—This contract, which comprehended the most extensive excavation on the line, is now nearly completed. The whole of the excavations and embankments are ready for the further opening to Denbigh Hall, except that about 4,000 yards of permanent road remain to be laid, not in one length, but made up of several smaller portions. The greatest quantity, to be laid continuously, is about one mile at the south end of the great excavation, for executing which quantity, as well as all the other unfinished parts of the permanent road in three weeks, every arrangement was made at the latter end of December. It has, however, been impracticable to proceed as intended, owing to the intense and protracted frost which set in a few days after the beginning of the year, continuing up to the present date without a single available interval of one day. The contractors have been urged, and every expedient resorted to, for the purpose of proceeding with the permanent road so as to expedite the approaching opening, but without success. There still remains work, which, as nearly as can be calculated, must require three weeks to perform, after a thorough thaw has taken place. The embankments throughout this contract consist almost entirely of chalk, which being already well consolidated and little liable to subsidence, the immediate use of the permanent road may be reckoned upon as soon as completed.

"*Leighton Buzzard Contract.*—This contract is in a very similar position to the last, though in a more forward state. The excavations and embankments are completed, and the permanent road laid, with the exception of about a mile, made up of separate portions. The ballasting is all on the ground, and nothing remains to be done but laying the rails and blocks, which are also on the spot. The Sinslade Tunnel is completed, one line of permanent road laid through it, and the fronts so far advanced, that executing the remainder of the stone and brickwork will form no impediment whatever to the opening.

"*Stoke Hamond Contract.*—The excavations and embankments are completed, except a small portion left on the slopes of the cuttings, which cannot interfere with the permanent road. Of this there remains little more than a mile to lay in different places.

"*Bletchley Contract—completed, except 350 Yards of Permanent Road.*—This contract terminates at Denbigh Hall, where a station is now being formed for the temporary terminus of the London division of the line. The shed for the engines and coaches is erected—the necessary turnplates fixed—the sidings stopped from the frost, but in a state to be finished in a fortnight; the huts for the engine-men are ready to be inhabited—the stables for Chaplin and Co. in a forward state—a small office erected on the bridge over the turnpike road, and an approach to the level of the railway from the turnpike road nearly completed.

"From the above statements relative to the work remaining to be done between Tring and Denbigh Hall, it is evident that the time of opening through this district depends on and must be regulated by the completion of that portion of the permanent road remaining unfinished at the south end of the Tring excavation.

"*Wolverton Contract.*—The whole of the works on this contract have for some time past been advancing in the most satisfactory manner. The quantity remaining in the Denbigh Hall excavation does not now exceed 50,000 yards; part of which is to be conveyed into the Wolverton embankment, and the remainder thrown into spoil. The present rate of progress will justify the calculation that the cuttings and embankments, including the Wolverton embankment, will be closed in eight weeks from this time. The permanent road is also in an advanced state. The unfinished portion is less than two miles, the greater part of which will be laid before the excavations are finished. We may, therefore, calculate upon the permanent road being extended from Denbigh Hall to Wolverton in eight or nine weeks.

"*Wolverton Viaduct Contract* completed, with the exception of the permanent road, which cannot be commenced until the embankment is brought up to both ends.

"*Castlethorpe Contract.*—The excavations and embankments may be regarded as completed, the latter are entirely so. On the slopes of the excavations a quantity of rock is left purposely, the chief part being intended for ballasting the permanent road, of which there is yet to be completed a length of $2\frac{1}{2}$ miles. This does not much exceed the quantity stated as remaining on the last contract; and as the excavations are more advanced, the period for completion may be reckoned the same.

"*Blisworth Contract.*—The progress made throughout the works of this contract has, upon the whole, exceeded the estimated average. Hitherto this was to have been expected from the favourable position of the material excavated, and the large quantity thrown into spoil; but the character of the excavation is now more difficult, and as it gets deeper, the space for employing men gradually becomes more confined. The material is increasing in hardness, and within the last few weeks there has also been

a greater quantity of water. These impediments naturally render any estimated quantity which may be yielded by the south end of the excavation for the embankment southwards in some degree uncertain. An arrangement has, therefore, been made, and is at present acted upon, for throwing an additional quantity into spoil from the centre of the excavation, and supplying the deficiency in the embankment by a corresponding quantity of side cutting at the southern extremity of the contract. The object thus aimed at, is the completion of the south portion of the contract in May, nearly at the same time with the Wolverton and Castlethorpe contracts, at which period an extended opening may be made from Denbigh Hall to the village of Roade, situate on the turnpike road, leading from Stony Stratford to Northampton, and only five miles from the latter town. This position appears highly advantageous for the next temporary terminus, which must remain the terminus for the London division until the opening of the whole railway.

"In the Blisworth cutting there now remain about 100,000 cubic yards of material, which will be disposed of nearly in the following manner:—30,000 cubic yards to Ashton embankment; 35,000 cubic yards to Blisworth ditto; 35,000 cubic yards to spoil. The first quantity is that which relates to the opening of the line as far as Roade; and reckoning the south end of the cutting to yield at the rate of 10,000 yards per month, this may be effected in three months, allowing the necessary time for joining the permanent road.

"The completion of the Blisworth embankment will probably not much exceed the end of May, from which date the undersetting will commence. By the time this has advanced to the site of the spoil, it is expected the excavation will be cleared to the level of the permanent rails. The undersetting being a work of a novel character, and placed in a situation where contingencies will in all probability occur, there is some difficulty in calculating the time it will require. After giving the subject the most attentive consideration, I do not deem it advisable to state this at less than three months from the time of the excavation being entirely cleared or bottomed, bringing to the end of September the completion of the contract as regards readiness for the opening of the line.

"The future method of procedure and expenses in the Blisworth cutting have been calculated upon the evidence and appearances now before us, but it is not improbable that in the undersetting our plans may require modification as indicated by circumstances at the time. Such cases will necessarily increase the cost beyond what was last estimated; but the quantity of materials now remaining in the cutting being small, and a considerable portion of the space for undersetting being exposed already, the additional expense cannot, it is thought, be very considerable. Three miles of permanent way remain to be laid.

"*Bugbrook Contract.*—The excavations and embankments throughout this contract are closed; but it will be necessary to deposit an additional quantity of material upon one of the embankments, in which there has occurred a very extensive slip. About 2½ miles of permanent way remain to be laid.

"*Stowe Hill Contract.*—This contract is in a satisfactory state as regards the prospect of completion. The tunnel has been finished some time. A small quantity of excavation is yet to be brought from the south end of the tunnel to the embankment at the north end of the contract. There are about 600 yards of permanent road to lay.

"*Weedon Contract.*—The excavations and embankments are completed. There are about 1,100 yards of permanent road to lay, and the greater proportion of ballasting is on the ground.

"*Kilsby Tunnel.*—This work is at present in a very satisfactory state, and the monthly progress as regular as can be expected, considering the nature of the operations. No new difficulty has recently occurred, except the capricious appearance and disappearance of water in some of the shafts, both in and beyond the quicksand. Between these shafts the junction of the respective portions of the tunnel has consequently become rather uncertain, the actual rate of progress in tunnelling through the intermediate space falling short of what was estimated. To remove this source of contingency as much as practicable, it has been found necessary to sink additional shafts, for the purpose of dividing those unfinished portions which would require the longest time to execute, or in which our average rate of progress was most likely to be interrupted by water or a change in the nature of the strata. On the 20th of January last a careful admeasurement was made, to determine accurately the distance unfinished between each pair of shafts, and the time of completion for each calculated upon an average which there are no reasonable grounds for doubting. The results are stated in the following table:—

Quantity remaining between Shafts. Between.	Yards.	Progress per Month. Yards.	Time of completion. Months.	
1 *a* and 1 *b*	33	6	5½	say end of June.
1 *b* and 1 *c* ...... 44 to be done from intermediate shaft X 14	30	6	5	say middle of June.
1 *c* and *d* ...... 40 to be done from intermediate shaft Y 10	30	6	5	say middle of June.
1 *d* and 2 ...... 54 to be done from intermediate shaft L 16	38	6	6⅓	say end of July.
2 and V shaft B	53	9	6	say middle of July.
V shaft B and 2 *b*	69	12	5¾	say middle of July.
2 *b* and 3	17	12	1½	say middle of March.
3 and 3 *a*	25	12	2	say end of March.
3 *a* and V shaft A	28	12	2⅓	say middle of April.
V shaft A and 5	15	12	1¼	say end of February.
5 and 5 *a*	37	12	3	say end of April.
5 *a* and 5 *b*	37	9	4	say end of May.
5 *b* and 6	42	9	4⅔	say middle of May.
6 and 6 *a*	30	6	5	say end of June.

The averages of progress adopted in the table may appear to be scarcely borne out by reference to the reports of progress in some particular shafts; but such instances are accounted for, either by the occurrence of a fallen length (which was the case in one of the quicksand shafts), or by the proximity of the face of the tunnel to the shaft, which lessens the room for working, and invariably reduces the rate of progress below that which ought to be taken as a guide.

"The circumstances requiring the adoption of the expedients explained above (in order to avoid disappointment by the further protraction of the time fixed for final completion), have necessarily caused the expense of prosecuting this work to be materially augmented beyond what was estimated last year; and in addition to this, it has been found absolutely indispensable to increase the prices of mining, timbering, and brick-work, formerly paid to the sub-contractors, and which expense was proved to be altogether inadequate. In the quicksand especially, although effectually drained, the utmost caution in mining has been required, and an expenditure of timber unavoidably incurred, which would appear excessive and lavish to any one whose experience has been confined to ordinary tunnelling. The present plans of proceeding have been arrived at by close observation and mature reflection, and cannot with safety or propriety be altered for the purpose of economising. Several circumstances have occurred, demonstrating that none of our precautions or expenses have exceeded what the magnitude of the difficulties attending the work imperatively demanded.

"*Brockall and Long Buckby Contracts.*—These two contracts are under the same contractors, and have been worked conjointly; they may therefore be regarded as one, with reference to completion. The works are in a more backward state than they ought to be. There is an excavation at each extremity; one, near Weedon, containing 70,000 cubic yards; the other, at the south end of Kilsby Tunnel, containing 80,000 cubic yards. From these two excavations one intermediate embankment is to be formed, requiring 97,000 cubic yards. The redundancy of the excavations is to be deposited in spoil. With moderate exertions, these works may be closed in four months. There remain about 4½ miles of permanent road to lay.

"*Rugby Contract.*—This contract having been given up into the hands of this Company, is now proceeding under the direction of the engineers. A considerable proportion of the excavations, embankments, and permanent road is already executed, and there now remain two excavations to complete; one of them, at the north end of Kilsby Tunnel, containing 143,000 yards—the other, near Rugby, containing 102,000 yards. The quantity to be conveyed from each to the Hilmorton embankment is almost 60,000 yards, which will occupy four months, making the period for completing this contract extend to July; and to this we must add one month for the permanent road, making it the beginning, or say the middle of August.

"*Rugby Station.*—The works at this point are at present in rather a backward state, owing to the severe and continuous frost, which has almost entirely put a stop to the brick-work and permanent road. The booking-office walls are built, the timbering of the roof put on, the engine and tank-house in a forward state, as also the huts for the engine-men. The turnplates will be fixed in a few days. The completion of the permanent road will occupy a fortnight after it is practicable to commence laying it.

"From this station to Birmingham one line of permanent road is laid throughout, and the other, with the exception of a short distance (about 150 yards) in the Church Lawford cutting. Though laid, however, the road is not in a fit state throughout to be travelled upon by engines and trains; for on some of the principal embankments it requires to be raised and adjusted. But this is a work which with the proper number of men can easily be completed before those other points already specially alluded to, as regulating the approaching opening.

"*Birmingham Station.*—The large turnplate in the locomotive engine-house is completed, and the necessary rails fitting it for the reception of engines will be laid in a few days. The lines of rails in the passenger sheds are laid, and the requisite sidings will be completed in a fortnight.

"From the foregoing remarks on the respective contracts throughout the line, it will be perceived that the works, now remaining to be executed, are not only confined to a few points, but also limited in magnitude. Blisworth alone appears to involve difficulties which may possibly interfere with our calculations and prospects. From Denbigh Hall to Blisworth the works are now rapidly approaching to a close. The great feature of that portion of the line—the embankment over Wolverton Valley—will be joined to the viaduct in about a month; and the line virtually finished and prepared for passengers as far as Roade, in the course of May next. The unfinished portion of the line will then be confined to the distance of miles between Blisworth and Rugby; but the greater portion of this length is at present nearly complete, and the only works of any magnitude remaining are

"I. The Blisworth excavation, now containing not more than 100,000 cubic yards of materials to be removed.

"II. The Long Buckly contract, with two excavations, both of which may easily be executed in less than four months.

"III. The Kilsby Tunnel, with 400 yards of tunnelling to do, divided into portions so limited in extent, that the calculated periods for the junctions being formed between the shafts (as detailed in the table given under the proper head), may be looked forward to with almost entire confidence; and

"IV. The Rugby contract, now in a very forward state; the unfinished works being confined to two excavations, favourably situated and circumstanced for suitable measures being adopted to secure their expeditious completion.

"Of these four points there are two, the Long Buckly and Rugby contracts, which involve no difficulty whatever, the works being quite of an ordinary character; of the remaining two, Kilsby and Blisworth, it is only the latter which need be regarded with particular anxiety, and this work it does not appear impracticable to complete in time, should the approaching season prove favourable. Unless there should be impediments to the undersetting of the rock with masonry exceeding what is at present anticipated, we may reckon upon an opening through it in six months from the 1st of March next, which would make its completion almost, if not actually, simultaneous with that of Kilsby Tunnel." "ROBERT STEPHENSON."

GREAT WESTERN RAILWAY.

Extracts from Mr. Brunel's Report to the Directors.

"The Company's works at Paddington are going on with spirit, and the station, which is intended to serve all the purposes of passenger traffic, until the whole line is opened, will be completed in ample time. The engine-house is finished, and the carriage sheds are in a forward state.

"A settlement of the Hanwell embankment occasioned at one period some anxiety, and involved the necessity of precautionary works to prevent any serious consequences; although the subsidence was at the worst much less than has been

observed in similar embankments on other works, it was thought desirable to take the most decisive steps to remedy the evil; and these, judging from the gradual diminution in the movements, appear to have been successful. In all other places the embankments are firm; and it may be stated generally, that the brickwork and masonry are exceedingly substantial and good.

"The bridge across the Thames beyond the present temporary station at Maidenhead, which is one of the most important works of the Company, is in a very forward state, the arches having been turned for about two months, and the centering will be eased very shortly.

"The works from that point are steadily progressing, and assistance will be given to complete the embankment beyond the bridge, from the eastern side of the river. The opening to Twyford will be expedited as much as possible, but must in a great degree depend upon the facility with which the supply of material for the permanent way may be obtained. The contract for the works expires in the month of May.

"At Sonning, the excavations are proceeding without intermission, and satisfactorily, as regards the execution; but it is clear to the directors that the contractor will not finish the open cutting there at the time specified in his engagement. From Reading to Didcot, where the Oxford branch will unite with the Great Western Railway, the work is divided into five contracts, two of which have been already let to a highly responsible contractor. Tenders for two other contracts have been invited for the 22nd March, and these, with arrangements making by the Company for the execution of an intermediate portion, will constitute the whole work to Didcot. The work on the space intervening between that place and Shrivenham is very light, and will be commenced in the course of the summer, and cannot occupy more than fourteen months in construction.

"From Shrivenham to Chippenham the earthwork is heavier, and will consequently be first undertaken, so as to be completed within the same time as the Box Tunnel, and those works which govern the opening of the entire line, and which have been been contracted for; the principal of these works being the contract between Chippenham and the eastern end of the Box Tunnel, which has proceeded satisfactorily, considering the nature of the work and the unfavourable state of the weather.

"The entire length of the Box Tunnel has been undertaken by contractors of character, ability, and property, and on terms satisfactory to the Directors and Engineer, though higher than had been originally contemplated; an increase that may be attributed chiefly to unfavourable rumours industriously circulated, of difficulties presented by the soil, and of the length of time that would be necessary for the performance of the contract. The Directors have, therefore, peculiar pleasure in stating, that the first-mentioned impediment has, in fact, no existence; the principal part of the tunnel, as shown by the shafts now completed, being carried through Bath stone, and the remaining portion through the Lyas limestone, and so firm and dry a marl, as gives equal assurance, both of the security of the works, and the certainty of its progress; whilst the answer to the second imputed difficulty, will be found in the fact of the whole having been contracted for to be completed within about thirty months.

"Every effort has been made to expedite the progress of the works between Bath and Bristol. The peculiarly laborious nature of these can only be fully understood by such as are well acquainted with the general localities of the line in this district, and are of a kind, which, when considered in connexion with the dimensions of the tunnels, the facilities of the levels, and that superior degree of completeness throughout the whole, which it is the object of the Directors to attain, will, in a great degree, account for its construction having been less expeditious than was anticipated, although they feel it to be their duty to state, that independently of these circumstances, the rate of progress made in part of the work under contract has not equalled their just and reasonable expectations.

"The peculiarity of the plan which has been adopted, consists principally in two points; first, in the use of a light flat rail, secured to timber, and supported over its entire surface, instead of a deep heavy rail, supported only at intervals, and depending on its own rigidity. Secondly, in the timbers which form the support of this rail being secured and held down to the ground, so that the hardness and degree of resistance of the surface upon which the timbers rest, may be increased by ramming to an almost unlimited extent.

"The first, namely the simple application of rails upon longitudinal timbers is not new; indeed, as mentioned in a former Report, I believe it is the oldest form of railway in England, but when lately revived and tried upon several different Railways, it has not, I think, succeeded as fully as was anticipated, and I believe this is very much owing to the want of some such means as that which I have adopted for obtaining a solid and equal resistance under every part of the timber, and a constant close contact between the timber and the ground. As I believe this to be entirely new, and to constitute an essential part of the plan, I trust I shall be excused dwelling upon it for the purpose of fully explaining it.

"In all the present systems of rail laying, the supports, whether of stone blocks or wooden sleepers, simply rest upon the ground, and, consequently, only press upon the ground with a pressure due to their own weight: this is trifling, compared either to the weight which rolls over them, or even to the stiffness of the rail which is secured to them. The block or sleeper must lie loosely upon the ground; if you attempt to pack under it beyond a certain degree, you will only raise it, and for the same reason, it is impossible to pack under the whole surface of a block or sleeper; one corner or one end is unavoidably packed a little more than another, and from that moment the block or sleeper is hollow elsewhere. If this block yield as the weight rolls over, the rail itself, resting on the two contiguous supports, is sufficiently stiff to raise it again, and the support becomes still more hollow; such is the operation, which may frequently be observed by the eye, more or less, in the best laid railways.

"Where continuous longitudinal sleepers have been tried, they have also been laid loose upon the ground; having no weight in themselves, their length has rendered it impossible that they should be well supported by the ground underneath, or that they should continue so, even if it were practicable to lay them well in the first instance.

"It will be perceived at once that two lumps or two hard places in the ground may leave such a timber unsupported for the interval of twenty or thirty feet in length, and, under the weight of an engine running rapidly over, it must in such a case yield and spring from the ground.

"In the present plan these timbers, which are much more substantial than those hitherto tried, are held down at short intervals of fifteen to eighteen feet, so that they cannot be raised; gravel or sand is then rammed and beat under them, until at every point a solid resistance is created, more than sufficient to bear the greatest load that can come upon it; as the load rolls over, consequently the ground cannot yield—the timber which was held tight to the ground cannot yield, neither can it spring up as the weight leaves it; and if the rail be securely fixed every where in close contact with the timber, that also is immoveable: such was the theory of the plan, and the result of the experiment has fully confirmed my expectation of success.

"The experiments have been made under several disadvantages, and I am glad that it has been so, as we are more likely to perceive at once, and to remedy any defects which might otherwise have lain concealed for a time. The packing, upon which it is evident every thing depends, was effected during long-continued wet, and while no drainage at all existed: looking forward to the necessity of re-packing once or twice, the timbers and packing were left completely exposed. The severe frost which immediately followed converted the wet sand into a mass of stone, which we have in vain attempted to disturb, and the continued dry frost has gradually evaporated the water it originally contained. The packing has shrunk considerably, and the exposed surfaces crumbled away, while the mass is still so hard within as to resist the pick-axe, and has been with difficulty broken through at some points with a smith's cold chissel and hammer. Under these circumstances, with an engine weighing between fourteen and fifteen tons (and from want of adjustment, with more than half of this occasionally thrown upon one pair of wheels) constantly running over the rails, the timbers have stood most satisfactorily."

To render the report as explanatory as possible, we have annexed engravings of the Railway as adopted on the embankment near Maidenhead, drawn to a scale of 8 feet to 1 inch. —EDITOR.

Fig. 1 and 2. Transverse Section and Plan of Railway.

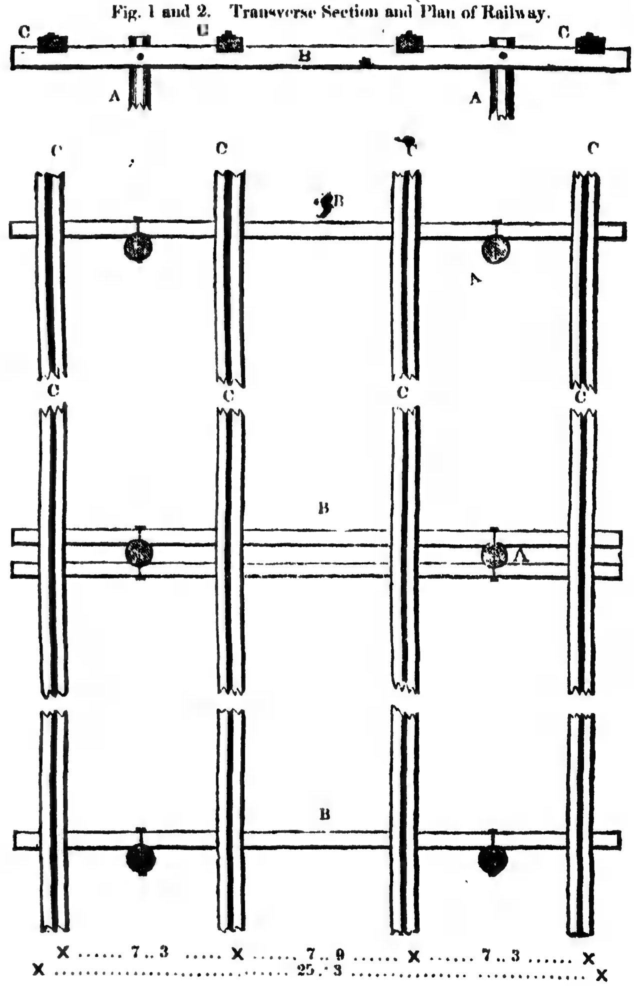

Fig 3. Fig. 4.

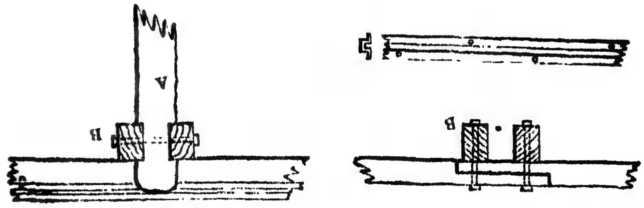

Fig. 5.

A Piles of beech timber 10 and 9 inches diameter, and about 8 feet long.

B Cross beams or transoms of *pine* timber, 13 inches by 6 inches, which are framed and fastened to the piles with iron bolts. These transoms are placed at 15 feet apart, and are placed alternately double and single, as shown in the drawing.

C Longitudinal Sleepers of Pine timber 9 by 6 inches, upon which the rails are fastened, as shown at large in Journal No. 5, page 105, with a piece of wedge-shaped hard wood, between the rail and the sleeper. A piece of felt is laid under the rails.

Fig. 3, is a side view of the Sleepers, at one of the joints, showing the way they are fastened down to the cross beams.

Fig. 4, is a side view (drawn at double the scale of figs. 1 and 2) of the rail, sleeper, cross transoms, and one of the piles, showing the way they are fastened together.

Fig. 5, is a plan of the rail, showing the holes that are punched in the flange for the screw to fasten the rail down to the sleeper.

Note.—All the timber is *Kyanized.*

IMPROVEMENTS IN STEAM NAVIGATION.

At the last Annual Meeting of the British Scientific Association, held at Liverpool, a grant of money was placed at the disposal of a committee, to investigate the actual performance of steam-vessels, with reference to their speed, consumption of fuel, and other circumstances affecting their general efficiency. This investigation arose from a discussion which took place in the mechanical section, in the course of which statements the most conflicting were made, even by practical men, as to the capabilities of steam-vessels for extended navigation. In prosecuting their inquiry, the committee have thought it desirable to adopt some method of registering the actual performance of the vessel in a log, which will not be subject to the errors and neglect which have hitherto rendered all steam-logs more or less useless.

With this view Dr. Lardner has attempted to construct a piece of mechanism, which will enable the steam engine itself to write the journal of its own proceedings. This mechanism is now being constructed, and is intended to be placed in the *Tagus*, a large and powerful steam ship belonging to the Peninsular Steam Navigation Company, this Company having liberally offered to co operate with the committee.

The circumstances on which principally the efficiency of the machinery and the vessel depends, and which it is necessary to register, are the following:—

1. The height of the barometer-gauge, which indicates the state of the vacuum produced by the condenser.
2. The height of the steam-gauge, which indicates the actual pressure of steam urging the piston.
3. The height of the steam-gauge, which indicates the actual pressure of steam in the boiler.
4. The number of revolutions of the paddle-wheels per minute.
5. The depth of water in the boiler.
6. The degree of saltness of the water in the boiler.
7. The rate of the vessel.
8. The draught of the vessel, or her immersion.
9. The direction and force of the wind.
10. The course of the vessel.

The mechanism now being constructed will keep a self recording register of the first six of these. A provision is, however, made for subsequently adding means of registering the seventh and eighth, should it be found desirable to do so. The consumption of fuel will be easily determined by keeping an account of the quantity of coals delivered into the vessel at each port, making an allowance for what is consumed in the steward's room, kitchen, and cabins.

A float is placed on the mercury in the barometer gauge, from which a rod proceeds, to which the pencil is attached. As the column of mercury rises or falls, the pencil receives a corresponding motion; and being pressed against the paper on the cylinder, leaves a trace upon it, which measures the extent of the variation of the mercurial column.

The heights of the steam and other gauges are registered in the same manner by other pencils.

The entire apparatus will be enclosed in an octagonal case, about three feet and a half high, and three feet diameter. It will be locked by the agents of the owners when the vessel starts on her voyage, and will not be opened till her return. It will require no other attendance during the voyage than that of winding the clock.

The several pencils will be of different colours, so that their traces may be easily distinguished one from the other. Besides which, it will be arranged that their play may be confined to different parts of the cylinder.

At the end of each voyage the paper will be removed from the cylinder, and replaced by a clean sheet.

If it be thought advisable, the indications of the several curves traced by the pencils may afterwards be translated into the ordinary language of log books.

It is not improbable that an anemoscope and other apparatus may be contrived, by which the direction of the wind and the course of the vessel may likewise be recorded—at least, with as much precision as they are now ascertained by other and less regular expedients.

If this mechanism should succeed in attaining the objects for which it has been contrived, besides its valuable scientific results, it will be productive of great benefit to the proprietors of steam-ships, by supplying to them a never-failing check on every one concerned in the management of the vessel. Thus any relaxation of attention, or want of skill on the part of those in care of the fires, will be indicated by the third pencil. Any neglect in feeding or blowing out the boilers will be indicated by the fifth and sixth pencils. The attention to the state of the condensing apparatus will be shown by the first pencil.

In the event of the temporary suspension of the operation of the machinery for adjustment, or any other cause, the fact of such suspension, its duration, and the time it took place, will be also recorded.

By the connexion of all the indicators with the timepiece, the exact hour, or indeed minute, of each registered circumstance will be recorded.

Monthly Chronicle.

THE "GREAT WESTERN STEAM SHIP."

This vessel is now out of dock; she has been during the last fortnight making trials of her machinery previously to leaving the river Thames for her return to Bristol, from which place it is expected she will take her departure for New York early in the present month. The Directors of the Company have spared no expense to render her a truly magnificent vessel, worthy of trading between two such great and powerful nations as England and America; they have been exceedingly judicious and cautious in selecting all the parties in any way connected with her build; Mr. Patterson was engaged as the Ship-builder; Messrs. Maudsley, Sons, and Field, of London, as the Engineers; and Mr. J. K. Brunel, as Consulting Engineer, who gave his valuable services *gratuitously*. The dimensions of the vessel are—

Length between perpendiculars 217 feet, length over all 234 feet, beam 35½ feet, breadth from out to out of the paddle-boxes 58 feet, depth 23¼ feet, and registered admeasurement 1340 tons. Her floors are of great length, and overrun each other; they are firmly dowelled and bolted, first in pairs, and then together by means of 1½ inch bolts, about 24 feet in length, driven in four parallel rows, scarfing about 4 feet. The scantling is equal in size to that of our line-of-battle ships; it is filled in solid, and was caulked within and without up to the first futtock heads previously to planking, and all to above this height of English oak. She is most firmly and closely trussed with iron and wooden diagonals and shelf pieces, which, with the whole of her upper works, are fastened with screws and nuts, to a much greater extent than has hitherto been put in practice. She has stowage for 800 tons of coal, or coal and cargo combined, without touching upon her provision and water room for 300 people. Besides ample space for officers and crew (comprising about 60 persons), there are state rooms, &c., for 128 first class passengers; there are also 20 good secondary berths; and should it eventually be found advisable to forego cargo space altogether, about 100 more sleeping berths might be easily and conveniently arranged. Such of her timbers as may be exposed to alternations of dryness and moisture has been prepared by Kyan's patent process; and every effort has been made to combine the various points of naval architecture and engineering, so as to render them most effectual in a service requiring speed, strength, and accommodation, and in which she will have to compete with the finest sailing passenger vessels in the world.

Her engines, which were the admiration of all parties who saw them, were manufactured by Messrs. Maudsley, Sons, and Field, justly eminent for the superiority of their workmanship; they are the two largest marine engines that have been made, and are equal to 450 horse-power. The boilers are constructed with several adaptations for the economy of steam and fuel, on an entirely new principle, which has greatly economised space, and, it is believed, will very much lessen the consumption of coal. They consist of four distinct and independent boilers, so that the engineer can work such number only as circumstances may require; while, by means of passages reserved between them, he can cool, examine, repair, and clean those not in use. The wheels have the cycloidal paddles, which are of iron, and possess decided advantages.

In studying the convenience, comfort, and decoration of the cabins, points which are of great importance in a vessel carrying passengers of a superior class, the Directors have engaged the services of artists and tradesmen recommended for their taste and experience. The ornamental work of the principal apartment will be found as well adapted to its purpose as it is novel and beautiful in its application, which we understand was intrusted to Messrs. Jackson and Sons, of Rathbone Place, London, who, we are happy to say, have fully executed their trust with considerable skill, taste, and judgment.

The Saloon, which for size and splendour exceeds any that we have seen afloat, is seventy five feet in length and twenty one feet in breadth, exclusive of the recesses on each side, where the breadth is thirty four feet, and nine feet high in clear of the beam, which is increased by the lanthern lights; each side, excepting where the recesses intervene, are occupied with *state cabins*. The ornamental work is very judiciously arranged, there being neither a profusion nor paucity of decoration. The front of the two recesses is divided into three compartments by small columns, formed in imitation of palm trees, with branches of leaves entwined over the openings, which have a neat and pleasing effect. At each end of these two recesses are large pier glasses, fitted in richly ornamental frames, in imitation of Dresden china. The fronts of the small cabins are divided into compartments, with panels about five feet high, and one foot six to two feet wide, tastefully decorated by no less an artist than *Edward Thomas Parris*, R.A., and historical painter to Her Majesty. Each panel contains an admirable painting in the *Wateau style*, representing rural scenery, agriculture, music, the arts and sciences, interior views and landscapes. Above the doors are small panels, containing (by the same artist) beautifully pencilled paintings of Cupid, Psyche, and aerial-like figures, which considerably heighten the appearance of the saloon. The ceiling and such parts of the saloon not occupied with the paintings are painted by Mr. Crace, of Wigmore Street, of a warm and delicate tint with the mouldings and enrichments, picked in a light colour, and relieved in gold, not too much so as to give a gaudy appearance, but just sufficient to produce a richness of effect, without encroaching or detracting from the principal features of the saloon (Mr. Parris's paint-

ings). The small cabins on each side, and communicating with the saloon, each contain two sleeping berths, so arranged that in the day time they may be turned up against the side of the vessel, and conceal the bedding, thereby forming a small sitting room, seven feet by eight feet. At the end of the state cabin is the ladies' saloon, which is very tastefully fitted up by the upholsterer, and on the opposite side is the steward's room, containing every convenience to render this important department (to the passenger) complete. It is furnished with a supply of salt and fresh water, and one of Stirling's filterers. The arrangement of the bells is deserving of notice. In the steward's room, standing on a shelf, are two small mahogany boxes, about one foot long, and eight inches square, each containing a bell, communicating, by means of wires, to every berth, cabin, and other department in the vessel. When the attendance of the steward is required, the passenger pulls the bell rope in his berth, which rings the bell in the small box, and at the same time, by means of a small lever, forces up, through a slit in the lid, a small tin label, about two inches by one inch, with the number of the room painted on it requiring the services of the steward, and there remains until the steward has ascertained the number of the room, and pushed it down again. Thus, instead of having an interminable number of bells, one for every department, there are only two. This arrangement, which is alike ingenious as it is useful, is deserving the notice of architects. We understand it is the invention of a person residing at Greenock. Between the steward's room and the ladies' cabin, in the midship, is a spacious staircase, with handsome ornamental railing bronzed and gilded, the wood work painted in imitation of Pollard oak.

The figure-head of the vessel is deserving of notice: it is a demi-figure of Neptune, with his trident admirably carved and gilded; and on each side are dolphins, finished in imitation of bronze. The mouldings are also gilded.

We are happy to announce from our observation, when on board the vessel, at a time when she was crowded by noblemen and gentlemen of all ranks, besides several scientific persons well acquainted with the construction of steam ships, that all agreed that the build of the vessel, the exquisite workmanship of the steam engines, the beauty of the decorations, and the fittings in general, deserve their unqualified approbation and praise.

DIMENSIONS OF THE GREAT WESTERN STEAM VESSEL, ENGINES, BOILERS, &c.

	Ft.	In.
Length of vessel between perpendiculars	212	
Length of vessel *over all*	236	
Depth of hold	23	3
Extreme breadth of beam	35	4
Width from outside to outside of paddle-case	58	4
Draught of water (loaded)	16	
Burthen in tons, 1340.		
Diameter of paddle-wheels	28	
Length of paddle-boards	10	
Height of centre of shafts	18	5
Numbers of revolutions per minute, 15 to 16.		
Diameters of shafts, 15 and 16 inches.		
Width of bearings, 15 inches.		
Diameter of cylinders, 73 inches.		
Length of stroke	7	
Diameter of air-pump, 40 inches.		
Length of stroke of do.	3	6
Length from centre of shaft to centre of cylinder	19	6
Width from centre to centre of engines	13	
Four boilers of equal dimensions . . . Length	11	6
Width	9	6
Height	16	9

Weight of engines, about	200 tons.
Do. boilers	100
Water in boilers	80
Intended to carry coals in tons	600
Capable of carrying	800

Consumption of coals, 1¼ tons per hour, when engines are in full work; or 30 tons *per diem*.

600 tons will give	20	full days' consumption.
700 „	23⅓	„
800 „	26⅔	„

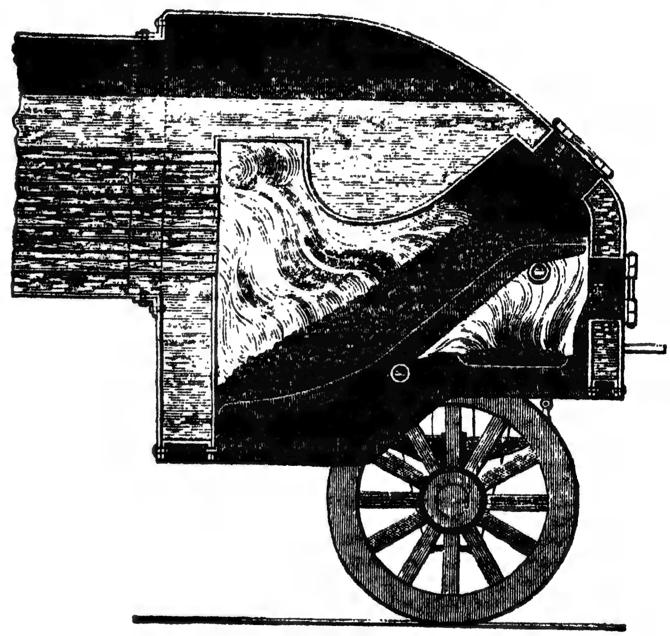
It is presumed that no voyage will require the full working of the engines for the whole time, but that favourable winds, for some part, will reduce the quantity of coals required.

The boilers and steam-pipes are to be clothed with a coating of red lead, felt (an excellent non-conductor), and canvass, which will not only prevent a great waste of radiating heat, but will also keep the engine-room and the vessel perfectly cool.

CHANTER AND GRAY'S PATENT SMOKE CONSUMER,

Applicable to Steam Boats, Locomotive Engines, Stationary, and other Boilers.

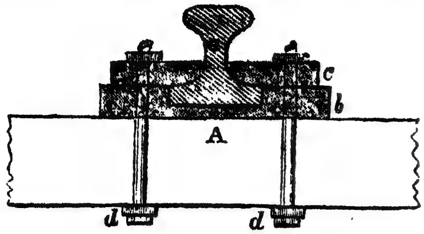
The principle of the smoke consumer essentially consists in so arranging the form of the furnace and position of the bars, that the fuel is regularly advanced by gravitation, upon inclined fire-bars, without the aid of machinery, or any apparatus besides the simple instruments in common use for the management of furnaces; the carbon and various inflammable gases are set free in the process of combustion, and being more charged with the oxygen of the atmosphere and heat of the fire, proceed through and over the fire, which, increasing in heat to its termination, gradually subjects the less combustible gases to perfect combustion. Saving in fuel is thus effected; for in the present furnaces, these are not only passed off unconsumed, but by preventing the ignition of more combustible materials, necessarily waste a large portion of the burning fuel. Thus the primary effect, in the operation of the patent furnace, may be stated to be that of obtaining, at the termination of the furnace, that intense degree of heat indispensable to the entire combustion of the various substances emitted from the burning fuel. This invention is exhibited in the specification in twelve different forms, showing its application to every description of furnace. The details are somewhat varied; but the most important part of the principle, namely, the absolute combustion of the vapour, is thus effected in all of them.



The annexed engraving is a section showing the adaption of the patent smoke-consumer to a locomotive engine. By reference to the drawing, it will be perceived that the furnace is made raking or inclining downwards at a considerable angle, which is so regulated that the fuel will gradually slide down as it becomes consumed; the larger, or more weighty fuel at the top, forces down that which has been partially decomposed, and so on, until it be reduced to a very small cinder, or ash, when it will drop through the aperture at the foot of the grating into the ash-pit. The furnace is charged in the following manner:—The coals are laid within side of the door, so as to completely fill the mouth of the furnace (and not thrown into the centre, as is generally adopted in the ordinary constructed furnace); here the coal is converted into coke, by the intense heat of the fuel below, which is in a high state of combustion; the smoke and gases arising from the fresh fuel is driven, by the great draught passing between the bars from the ash-pit, against the inclined surface of the underside of the boiler; hence it is reverberated on to the burning fuel, and completely consumed. In the ash-pit is placed a grating, or *saveall*, to catch the small coals which may drop through the bars, where they are consumed, and the heat arising therefrom passes into the furnace above, thereby saving a considerable portion of fuel that would otherwise have been lost.

The smoke-consumer has been, within the last few days, publicly exhibited at the Patentees' premises, in Earl Street, Blackfriars. Several of the most eminent engine-makers in the metropolis attended to witness it in operation. They all agreed that the patent was one of great importance, and that it effects a *perfect consumption of the smoke.* We were present for upwards of an hour, and witnessed several charges of fresh coal being put into the furnace, and during the whole of the time we did not see a particle of smoke escape from the chimney. The Patentees exhibited several models and drawings, showing how the consumer may be adapted to marine and other boilers.

AMERICAN RAIL AND CHAIR.



THE annexed figure is the section of a wrought-iron rail and wrought-iron chair, as adopted in America. The depth of the rail is uniform. The upper web is of the same form as the ordinary rail. The rib is plain, and varies from six-tenths to eight-tenths of an inch in thickness. The lower web is, in some examples, not so wide as the upper web by nearly half an inch, and in others it is somewhat wider. The depth varies from four and a half to five inches.

A, is the wooden sleeper, to which the chair is fastened; *a*, the wrought-iron rail; *b*, wrought-iron chair; *c*, wrought iron clamping-pieces, confining the chair by means of the two nut and screw bolts *d d*, to the sleeper.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

REPORTS OF PAPERS READ AND PROCEEDINGS, SESSION 1838.

(Continued from page 140.)

On the Application of Steam.

THE minutes of the discussion on Mr. Wicksteed's paper and the Cornish engines having been read, Mr. Parkes called the attention of the Institution to the importance of the question of the applicability or inapplicability of the Cornish system of using steam to condensing engines generally. It seemed to him, after the confirmation which the statements regarding the Cornish engines had lately received from the praiseworthy exertions of Mr. Wicksteed, that, as regards economy of fuel, the Cornish engine was even still more superior to the low-pressure engine, than the latter was (at the period of its invention by Mr. Watt) to the original atmospheric one; that there existed, indeed (if all we heard were true), less economical difference between Mr. Watt's and the high-pressure or non condensing engine, than between the Cornish and the common Boulton and Watt engine. If such were the case, which could now scarcely admit of a doubt, Mr. Parkes thought, that the interests of science and the arts demanded a much more thorough and searching investigation into the rationale of the Cornish engine than had yet been made; and he thought it a reproach to the Institution, that no one of its members is yet prepared to say, whence arises the superiority of the Cornish engine, nor what is the relative value of the various perfections which had been for so many years assigned to it by its employers.

Mr. Parkes thought that most engineers were agreed, that the low-pressure crank-engine, used for manufacturing purposes, required, in its highest state of condition, at least ten pounds of good coal per horse per hour; that such was Mr. Watt's own estimate, allowing one pound of coal for the evaporation of seven pounds of water. He had had many opportunities of proving—so far as the Indicator can be relied upon—the load and consumption of Boulton and Watt's own engines, as well as engines by other makers; but only in three instances had he found the consumption so small as ten pounds. He had only in one instance been concerned in ascertaining the duty done by a pumping engine—which was one of the same kind—not working expansively; and as this experiment was conducted with the most rigorous exactitude, the correctness of the results might be relied upon. The engine was nominally one of forty horses' power, constructed by Messrs. Hick and Rothwell, of Bolton, erected at St. Ouen, near Paris, and employed to raise water, by means of a scope-wheel, to supply a new dock. The experiments of two consecutive days were managed and checked by M. Arago, M. Jouy, Mr. H. Farey, and Mr. Parkes. By the Indicator, the engine proved to be working exactly to forty horses' power, with a consumption of eleven pounds of good Mons coal per horse per hour: but as the actual weight of water raised, one foot high per minute, divided by forty horses, attained 36,000 pounds, the real consumption was about ten pounds of coal per horse per hour. Mr. Parkes adduced this experiment, with an engine of the most perfect construction and in perfect condition, as evidence, that the duty of the common low-pressure crank-engine, not working expansively, does not exceed twenty or twenty-one millions of pounds raised one foot high by ninety or ninety-four pounds of coal; and thus that the Cornish engine, investigated by Mr. Wicksteed, exceeds such engine, in economy of fuel, in the ratio of five to one.*

Mr. Parkes then entered at some length into a consideration of the various phenomena to be observed, and facts to be ascertained, in order to determine the separate value of the parts of the system adopted in Cornwall. The assertion that the boiler was superior to others, would be confirmed or disproved by measuring the water evaporated by the fuel used—which might also be done with such accuracy, as to furnish us with the very important knowledge of the quantity of water in the shape of steam required for each stroke of the piston. A thermometric steam gauge should be fixed on the boiler, and another as near as possible to the cylinder, to determine both the pressure within the boiler, and at what pressure the steam really enters the cylinder. He suggested also that another such thermometer, fixed on the cylinder cover, might be useful, in conjunction with the Indicator, to determine the increments of expansion, as well as the highest and lowest degree of pressure within the cylinder. That it appeared to him the Cornish engineers had carried out to perfection Mr. Watt's axiom, that "the cylinder should be maintained as hot, and the condenser as cold, as possible," and that since the hot jacket probably played a still more important part to the cylinder of an expansive than to a non expansive engine, no means should be left untried to ascertain the value of that element. That the thermometric steam gauge might also be an useful adjunct to the barometer, in determining the amount of vacuum in the condenser, and other phenomena connected therewith. The proportions of the air-pump and condenser to the cylinder, adopted by the Cornish engineer, should also be noted, as well as the temperature of the injected and ejected water.

On the Expansive Action of Steam in Cornish Engines. By W. J. HENWOOD.

AT the commencement of this paper, the author describes, with great detail, the action of the Indicator, and the nature of the evidence which it furnishes on the working of an engine. The author then states the results arrived at on applying the Indicator to the cylinders of some of the best engines in Cornwall. The peculiar circumstances of each case, as the clothing of the boilers, steam pipes, and the various methods adopted for keeping up the temperature of the cylinder, are detailed. The steam cases or jackets of some of the engines were filled with dense steam from the boilers of others with heated air. The dimensions of the working parts and the loads of the engines; the water and steam in the boilers; the temperatures of the hot well of the condensing water, of the boiler shod, engine house, and external air; the duration of the experiments; the coals consumed, according to weight and measure; the quantity of oil and grease; the number of strokes; the duration of each experiment; and the pressures of the boiler and cylinder, are tabulated for the respective engines.

The greatest duty recorded as performed respectively by the measured bushel, by 84 pounds damp, and by 84 pounds dry, is $86\frac{1}{2}$, $72\frac{1}{2}$, and $77\frac{1}{2}$ millions.

Particulars of the Construction of the Floating Bridge, lately established across the Hamoaze, between Torpoint, in the county of Cornwall, and Devonport, in Devonshire; by JAS. M. RENDEL, *Member.*

THE width of the river Hamoaze, at the site of the bridge, is at high-water 2,550 feet, and low-water 2,110 feet. The greatest depth at high-water is 96 feet, and low-water, 18 feet. The strength of the current at ordinary spring-tides, is from 260 feet per minute, or nearly three knots an hour, to 330 feet per minute, or three knots three-fourths an hour, varying in different parts of the passage; but heavy land-floods, accompanied by a north-west wind, make the ebb tides run with a velocity of nearly five knots an hour.

The site lies directly at right angles to the line of current, a disadvantage that could not be avoided, as the mooring of the ships of war prevented the selection of an oblique line of direction, and the situation is so exposed, that ships lying in ordinary, in the immediate vicinity of the bridge, sometimes drag their moorings.

The bridge is a large flat-bottomed vessel, of width nearly equal to its length, divided in the direction of its length into three divisions, the middle one being appropriated to the machinery, and each of the side ones to carriages and traffic of all kinds. These side divisions or decks are raised from two feet to two feet six inches above the line of floatation; and by means of strong and commodious drawbridges or flat forms hung at each end of each deck, carriages drive on and off the deck from the landing places without difficulty, or occasion for the least disturbance of horses or passengers.

The bridge is guided by two chains, which, passing through it over two cast-iron wheels, are laid across the river, and fastened to the opposite stones. Two small steam-engines are employed as the moving power, by turning a shaft, on each end of which there is a large cast-iron wheel, whereon the guide chains rest. The landing-places on each shore are simple inclined planes, from low-water mark to two feet above high-water mark, formed to a slope or inclination of one inch twelve or one inch fourteen; and as the bridge approaches, the drawbridge is lowered on the plane.

To prevent the chains being so tight as to interrupt the free navigation of the estuary, or to endanger their breaking, instead of being fastened or moored to the shores, their ends have heavy weights attached to them, in shafts twenty feet deep and sixteen feet square at the head of each landing-place, the weights being cast-iron boxes loaded with five tons each, attached to the ends of the chains, which enter the shafts over cast-iron sheaves of two feet diameter. These weights rise and fall as the strain upon the chains becomes more or less, and prevents the tension ever exceeding the balance weights, which are considerably below the weight to which the chains have been proved.

The length of the bridge, exclusive of the drawbridges, is sixty-five feet; the width at midships, forty five feet; and at the ends, thirty-eight feet six inches. The draught of water, when the bridge is full of heavy carriages, is rather under two feet six inches, the clear depth of hold being four feet three inches.

The seat of the bridge in the water, or rather the lines of floatation, are elliptic, and the sides are curved vertically, the object of these forms being to

relieve the bridge as much as possible from the effect of the current, and to prevent the sudden stoppage of a wave, and the consequent spray over the side.

The roadways or decks have cross battens to prevent the horses' feet from sliding, and also for the better holding of a thin coat of sand and tar, as a more agreeable footing than wood. The fencing of the sides of the roadway is complete, by carrying the timbers three feet six inches to four feet above the decks, and above that by the chains which suspend the drawbridges forming a rail.

The drawbridges are of the same width as the roadways, and are suspended by two three-quarter inch chains; one of which, as before stated, forms a guard-rail to the side of the bridge; the other passes through the engine-house, being there connected with a small purchase machine.

There are two steam-engines, each having a cylinder of nineteen inches diameter, and two feet six inches stroke. They are common condensing beam engines, working at a pressure of three and a half pounds per inch in the boiler, and at an average speed of thirty five strokes per minute, and but one boiler. The feeding water is procured from a tank on the eastern landing-place, and the waste steam being thrown into this tank, is sufficient to raise the water to 100°.

The guide chains are of the common cable pattern, each one inch iron, and each link made to a gauge, so as to fit the chain wheels without slipping When the bridge is on either side of the river, and the chains lie on its bed. and when the bridge is in the act of crossing, they necessarily form two arcs, The weights in the shafts rise and fall from five to eight feet, according as the weather and the tide may happen.

The time of the bridge crossing is seven minutes at low-water, and eight minutes at high-water.

On the Evaporation of Water from Steam Boilers; by Josiah Parkes.

This paper contains the result of various experiments, conducted with the view of ascertaining the quantity of water which can be evaporated under particular circumstances by a given quantity of fuel. The results are tabulated with great accuracy, and all the authenticated data known to exist on this subject are brought together in a form in which they may be generally useful.

The author was induced to make sundry experiments on the supply of fuel and of air to the furnaces of the engine, with the desire to consume or diminish as much as possible the smoke and soot emitted from the chimney.

The furnaces had hopper mouth-pieces, with a provision for admitting a thin stream of air over the mouth-pieces into the fire, in order to consume the smoke; but which was of very little service, as volumes of smoke rolled forth from the chimney at each successive firing. Heavier and less frequent firing was adopted, and at the same time a careful admission of air over the hopper into the fire; but still the nuisance remained undiminished.

From the researches of Sir Humphry Davy on the safety lamp and on flame, it occurred to Mr. Parkes that the air must be given directly to the uninflamed gas at the point of greatest heat, the temperature of incandescence being necessary for inflammation; whereas, formerly, the air had become vitiated by passing over inflamed fuel, and that the bridge of the furnace was the most fit place for the supply of air, as it would there encounter all the inflamed and uninflamed gas, and obtain at all times the temperature necessary for ignition. Previously to the necessary alterations of the furnaces, the duty done by the coals, as ascertained by the evaporation of water, was carefully registered.

In respect to the firing of the furnaces, the author had observed that somewhat less smoke was emitted from less frequent than from very frequent firing, and that somewhat more water was evaporated by the same weight of fuel in the former than in the latter case. Also, that in consequence of less poking, fewer cinders were made; the dampers were lower, as there was a greater mass, though less intensity of heat; and the temperature of combustion being less elevated, there were fewer scoriæ. The operations of firing were gradually diminished, until a mode of working the engine with two charges of coal per diem was arrived at, the furnaces being loaded in the morning as rapidly as keeping up the steam would permit, with sufficient coal to work the engine till dinner-time. The grates were then cleaned, and charged again during the dinner hour, requiring no more coal during the day. The results attending these alterations were most important, viz., economy of fuel, steadiness of steam, much less smoke, still fewer scoriæ. On the re-construction of the furnaces necessary for the admission of air at the bridges, the whole capacity of the furnaces were enlarged, that they might contain at once the entire of the fuel requisite for the day's consumption, At the same time the boilers were covered with double arches of brickwork, leaving an air space between each arch and the boiler, coating the outer arch thickly with strong hair mortar, mixed with waste of wool. Eye-pieces were also made in the walls at the end of the boilers, opposite the fire doors, to obtain a view of what might take place at the bridges on opening or shutting the valves; also eye-holes for the side flues, to ascertain how far the flame extended. The results were now of the most satisfactory nature, no smoke being visible from about seven in the morning. The dampers were very close down, and capable of keeping the steam so steady, that it did not vary one-eighth of an inch in height for many hours. The furnaces, when charged, may be considered as great reservoirs of fuel, in a constant, equable, but moderate, state of combustion, not the entire mass on fire at once, but distilling first its gaseous products, and then gradually entering into combustion.

The greatest evaporation which was obtained from 112 pounds of coal was 18·5 cubic feet, supposing the water to have entered the boiler at 212 degrees. This was accomplished with both Netherton and Newcastle coal, the Wednesbury giving something less; whilst, before the introduction of the above-mentioned advancement, twelve cubic feet was the greatest evaporation.

This method, which had been followed so successfully, was subsequently made the subject of a patent, and applied to above 500 furnaces; but has gradually fallen into disuse, from its not being worth the master's care and time to see that the firemen do their duty. The author details a conversation which he had with Sir Humphry Davy, who had been making experiments on the temperature at the bridge, and the gaseous products of combustion; during which, that distinguished philosopher gave it as his opinion that the plan could never be established in general practice; that it was too simple, and depended on the fireman and not on the master, who will not concern himself with saving a few coals; that the same was his safety lamp; one half of the miners will not use it, but persist in working comparatively without light, and in danger of explosion, rather than adopt a simple contrivance which requires a small amount of trouble and care.

The paper is accompanied by four tables, the first of which contains the experiments made by himself; the second, the results of the Cornish boilers, from Captain Lean's report; the third, those of locomotive boilers, from De Pambour's work; and the fourth is a comparative table of the mean, greatest, and least results of the experiments on the three classes of boilers. The temperature of the water being different in the various experiments, a common standard is introduced by calculation, and the numbers express the quantity of water of 212° Fahrenheit, which would be evaporated by a given weight of coal.

	Cubic Feet.
The mean value of 112 lbs. of coal in evaporating water of 212° Fahrenheit is in the Cornish boiler	21·16
Mr. Parkes' Experiments at Warwick	18·5
——— in Lancashire	13·49
Ordinary boilers, and system of firing	14
Locomotion	10

Thus the efficiency of boilers being measured by the quantity of water evaporated by a given quantity of fuel, it appears that the boiler of the locomotives is far the lowest in the scale, and of the Cornish engines the highest. The paper concludes with a review of the state of our knowledge on the application of heat, and on the value of different kinds of fuel.

The Land Surveyor's Calculator; by George Heald.

The instrument to which the above name is assigned, was invented for the purpose of avoiding the necessity of performing long arithmetical calculations in surveying estates, the results being given at once by the adaptation and inspection of the instrument, as directed. It may also be applied to extracting the square roots of numbers, and the other purposes to which Gunter's scale is applicable.

The instrument consists of five concentric circles, whereof the four inner ones are on the outer edge of a card, moveable about a centre, and the fifth or outer circle is fixed.

The circumference of the fixed circle is divided into 1,000 logarithmic portions, representing links, and numbered 10, 11, 12, at every ten divisions, which numbers represent 1 chain; 1 chain, 10 links; 1 chain, 20 links, &c. From 1 chain to 1·5 chains these divisions are each subdivided into five parts, which serve to indicate the proportional parts of a link.

The next circle, formed by the graduated edge of the moveable piece of card board, is in all respects similar to the first, save that the divisions are carried round in the opposite direction. The second circle on the moveable card board represents areas and decimals, commencing with half an acre, and proceeding up to five acres.

The next circle divided into perches, to correspond with the preceding decimal division. It is numbered at every ten perches, and the acre is expressed at the termination of every rood.

The last, or fifth circle, is to show the area in acres, roods, and perches: when it is under two roods, it is numbered accordingly.

The author then describes the method of using the instrument for the solution of questions similar to the following. Having the diagonal and the two perpendiculars of a quadrilateral, or the base and perpendicular of a triangle; to determine the areas of the respective figures. The result is known at once in acres, roods, and perches, on inspecting either the fourth or fifth circle, according as above the area is greater or less than half an acre.

The instrument may also be used to the computing square yards, to the extricating square roots of numbers, and the ordinary operations of multiplication and division in the same manner as on other logarithmic lines.

A great advantage of this instrument results from the graduation being on the circumference of a circle. Great enlargement of the divisions is thus obtained, and in a far more convenient manner than by drawing a slide, as on the common sliding rule. The diameter of the outer circle in this instrument is sixteen inches; and to obtain divisions of the same magnitude, a rule with its slide drawn must be eight feet four inches. The author considers that a circle of eight inches diameter would be sufficiently accurate for practical purposes, and would render the instrument extremely compact and portable.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an Ordinary General Meeting of the Members, held on Monday, the 26th of February, 1838. J. B. PAPWORTH, Esq., V. P., in the Chair.

E. Lapidge, Esq., was elected a Fellow.

Several donations were announced as having been received.

Dr. Dickson delivered a lecture on the qualities of timber, and their application to construction.

T. L. Donaldson, Esq., Hon. Sec., described the sewer built under the Harrow-road, by the Great Western Railway Company, which had fallen in a short time since.

A communication was read from the Baron Wittersteaf, describing an anti-combustive mixture for the saturation of timber, so as to render roofs, floors, &c., less liable to ignition. The timber is to be placed in a vessel or trough, and hermetically closed, containing a solution of soda and water; the air is then to be exhausted by the aid of an air pump, and left for a period of six or seven days, when the atmosphere is to be re admitted; after remaining for a short time, the timber is to be taken out, when it will be found to be completely saturated with the solution, which consists of four to five pounds of soda, mixed with one gallon of fresh water. It will be better if the timber or deals be immersed in the solution after they are planed, or prepared for framing, and before they are glued up.

If cotton cloths, or other inflammable materials, be dipped once or twice in the solution, and mixed with a small portion of starch or glue, gum arabic, gum dragonant, &c., they will not inflame; but for wood no addition must be made of such glutinous substances, as they will prevent the liquidity of the solution, and impede the absorption in the fibres of the wood.

At an Ordinary Meeting of the Members, held on Monday, March 12, 1838, P. F. Robinson, Esq., V.P., in the Chair.

The following Gentlemen were elected as associates:— A. S. Hiscocks, of 83, Blackman Street, Boro'; Herbert Williams, Tonbridge Place, New Road. Several donations were announced as having been received.

A very interesting paper was read by George Godwin, Jun., Associate, on "The ruins of the Abbey of St. Bavon, at Ghent," in reference to the style of architecture known in England as Saxon and Norman, illustrated with sketches of the building.

Mr. R. H. Renton delivered an introductory lecture on the "Nature and Properties of Iron."

At an Ordinary Meeting of the Members, held on Monday, March 26, 1838. EARL DE GREY, President, in the Chair.

The following Gentlemen were elected as Fellows—*Thomas Fulljames*, of Gloucester; *William Rogers*, Palace Chambers, Lambeth.

As Associates—*C. A. E. Blair*, of Reigate; *Henry Clutton*, of Vernon Place, Bloomsbury.

Several donations were announced, among which was a Bust of the late Mr. Park, Architect, presented by Mr. Scoles, Fellow.

Several letters were received from Foreign architects who had been elected Honorary Members, and presented with the volume of the Institute's Transactions, expressive of their thanks for the high honour conferred on them.

Dr. Dickson then delivered the fifth and concluding lecture "*On the qualities of Timbers.*" The present lecture was principally confined to the decay of timber by fungi, dry rot, and the prevention of decay. He entered very fully into Mr. Kyan's process of preparing timber, by immersing it in a solution of corrosive sublimate, as a preventative of the dry rot; he explained in what manner it acted as a preventative of the dry rot; he stated that the corrosive sublimate solidified or coagulated the albumen, more particularly the sap wood, thereby preventing the fermentation of the wood and the development of fungi. We intend, in our next Journal, to give a brief abstract of the lecture.

The Noble President then called the attention of the Meeting to an important part of the proceedings of the Society, it having devolved on him, as President, to present the prizes to the successful candidates, awarded agreeably to the resolution of the Council, and confirmed by the Members at a meeting held on the 12th of February last, as reported in our Journal of last month, page 140, to which we refer for particulars. The several candidates, Mr. Samuel Sharp, Associate, Mr. George Edward Laing, and W. W. Pocock, Associates, were present. The Noble Chairman, in a very appropriate speech, presented to the former the Soane Medallion, and to the other two gentlemen the Medals of the Institute. The Institute passed unanimously a vote of thanks to *Mr. Andrews*, Fellow, of York (the unsuccessful candidate for the Soane Medallion), for the handsome manner he had acted in presenting to the Institute his Essay and Drawings of the restoration of the Abbey of St. Mary, at York.

At the conclusion of the business of the evening, the Noble President invited the Members and the Company present to his house on Monday evening, April 2nd.

ARCHITECTURAL SOCIETY.

Ordinary Meeting of the Society, held at their Rooms, 35, *Lincoln's Inn Fields*, 27*th of Feb.* 1838. T. H. WYATT, Esq., V.P., in the Chair.

Mr. Fripp, of Abingdon Place, Westminster, lately elected a member of the Society, forwarded his presentation drawings, agreeable to the laws, consisting of a design for "Scott's Monument," and a design for a "Park Entrance."

The ballotting for the sketches produced at the last meeting by the student members then took place. After which, the chairman called the attention of the members to the sketches the students member had produced this present evening, in competition for the prize to be awarded by Mr. George Mair, at the end of the session.

The subjects for the sketches proposed to be produced at the next meeting were announced—For members, "A design for an entrance to a palace;" for students, "A design for a gateway to a town entrance, with two side or foot-passengers' pathways; outer gateway to be 18 feet wide; side entrances, 6 feet wide, to be drawn to a ¼ scale, and tinted in lessia."

Monthly Meeting of the Society, held 13th of March, 1838.—*T. H. Wyatt, Esq., in the chair.*

The ballotting for the sketches commenced the business of this meeting, after which, those which had been prepared for this evening were produced for the consideration of the members.

Mr. John Woolley then read a highly interesting paper, offering sundry remarks upon the re-building of the Royal Exchange. Some sketches, principally of ornaments, were produced by Mr. John Henry Hakewill, which attracted general attention.

The subjects for the sketches proposed to be produced at the next meeting were announced as follows:—For members, "A design for a monument to Lord Nelson, adapted to the site of Trafalgar Square;" for students, "A design for a toll house, in the Tudor style, consisting of two rooms, besides a small portal, showing gates thereto."

A Special Meeting of the Society was held the 16th of March, 1838, for the transaction of private business, when it was announced that H. R. H. the Duke of Sussex had condescended to become patron of the Society, and a deputation was appointed to convey the warmest thanks of the members to this distinguished individual for the high honour which H. R. H. has thus conferred upon them.

ROE'S PATENT CLOSET BASIN.

SIR,—In the notice of my Patent Closet, in your last Journal, page 141, you say the principal improvement is in the cock, &c.; this is not the case, as the principal improvement (for which I have taken out a patent) is in the basin, and is the only part which gives a decided superiority over the common closet. I consider the cock is an improvement upon the common one, but that is a secondary affair. The closet is not always supplied by means of a cock, but can be supplied in different ways. *See advertisment.*

Camberwell Road, March 7th, 1838. F. ROE.

MEETING OF SCIENTIFIC SOCIETIES.

Civil Engineers' Institute every Tuesday evening.
Royal Institute of British Architects, Monday evening, April 9 and 23.
Architectural Society, Tuesday evening, April 10.

STEAM NAVIGATION.

New Steamer.—The Dublin company's new vessel, the "Duchess of Kent," arrived on the 1st day of March at the quay, on her first voyage. She is a beautiful vessel, of the same power and mould as the "Queen Victoria." The "Duchess of Kent" arrived at Kingstown in ten hours and forty two minutes from the docks at Liverpool. This fine vessel will, on being registered, continue to ply regularly between Dublin and Liverpool. The company's next new steamer, the "Royal Adelaide," is expected in Dublin immediately, when she will take up the line between this port and London. The "Royal Adelaide" is equal in every respect to the "Royal William." Two new steamers (already far advanced in building) will succeed the "Adelaide," and are expected to be ready for sea in the ensuing summer.

Glasgow.—The steam-ship "Commodore" has commenced sailing from the Broomielaw for Liverpool. We learn that this splendid vessel is the first of a train of similar vessels which her enterprising owners, the City of Glasgow Steam Packet Company, intend putting on the Liverpool trade; also, that both in build and machinery she is materially different from any other. Her quarter-deck, by extending over the engine-room, leaves a promenade of fully 150 feet in length—while a decided advantage is obtained in a mechanical point of view by allowing more space for the engines. It is expected, from the trial trips made, that she will not be surpassed by any vessel now afloat.

We understand that a direct steam-packet communication with Sweden is on the point of being re established between the ports of Hull and Gothenborg, the Swedish Charge d'Affairs in this country having entered into a contract with an English company for the conveyance of the mails.

Steam Navigation to New York. There is now fitting out in the port of London a steamer, which is intended to make the first experimental trip to New York. She is named the Columbus. She will be propelled by Mr. Howard's Patent Vapour Engines, and can carry fifty days' fuel at the same immersion as a steam vessel on the common plan, of equal power and tonnage, can carry twelve days' fuel. She will sail from the Thames for the Mersey as soon as the former river shall be free from ice, and will leave Liverpool shortly afterwards for New York.—*Liverpool Standard.*

An iron steamer, named "The Caledonia," built by Messrs. Carmichael, was launched from their works at Sea Braes on Wednesday week, in presence of a large number of spectators. She is the first iron vessel built here, and in regard to mould and workmanship does the utmost credit to her builders. She is to be fitted up with two engines of thirty-five horse power each, and is admirably adapted for river navigation.—*Montrose Review.*

The Columbus, an experimental steam boat, fitted for generating steam through the medium of quicksilver, and intended to supersede the use of coal to a considerable extent, put in here from Weymouth, on a cruise round land. The masters and officers report favourably of the principle so far.—*Jersey News.*

PROGRESS OF RAILWAYS.

Lancaster and Preston Railway.—Contracts for laying and completing the entire line of road will shortly be completed. Large purchases of land have also been made by the company, but some difficulty having been experienced in treating with certain owners of property on the line, it is not unlikely that a jury will, ere long, be summoned to assess the value of the land in question.—*Lancaster Guardian.*

The Midland Counties Railway.—When the frost takes its departure 3,000 men will be set to work between this town and Rugby, in the formation of the railway: the line, it is expected, will be opened in 1840.—*Leicester Chronicle.*

Great Western Railway.—The Directors have concluded contracts for the entire completion of the great tunnel at Box-hill, according to the plans and specifications of the engineer, Mr. Brunel. Although attended with far less difficulty, as an engineering work, than some of the tunnels now in execution upon the Birmingham line, the Box tunnel will prove one of the finest specimens of scientific skill and boldness which this country can exhibit. The permanent and temporary shafts have all been completed, and of course afford the most satisfactory proof of the nature and quality of the ground, which proves to be far more favourable in every respect than was anticipated. The larger portion of the tunnel will be through the oolite or Bath stone, and the remainder through a firm dry marl, which offers little difficulty in working. The Directors, we think, did wisely in giving the contractors such ample means of ascertaining the nature of the materials they have to encounter, as they have thus been enabled to secure the completion of the work on terms closely corresponding with the engineer's estimate, and not influenced by the exaggerated apprehension of difficulties which ignorance of the strata might create. The contracts have all been taken by Mr. George Burge, of Herne Bay, who is well known as contractor for the St. Katherine Docks, London, and whose high character for responsibility, energy, and skill, is sufficient assurance to the Proprietors that he will execute his contracts to the entire satisfaction of the Directors, and with the spirit and fidelity manifested in his former undertakings.—*Bristol Gazette.*

The Manchester, Bolton, and Bury Railway, it is said, will be completed the entire distance by the first day of May.

The Grand Junction Railway Company have made an application to Parliament for power to make a diversion from the present line, considerably southwards of Warrington (crossing the river at Fiddler's Ferry), to Liverpool.

Bristol and Exeter Railway.—The state of this line is now become very interesting from the vigorous prosecution of the works on the first twelve miles. Another powerful locomotive engine arrived this week, which will be running on the line near Backwell on Monday; and we understand the Directors and a large party of shareholders intend proceeding over the line, commencing with Pile hill on the Bath road, and ending with Backwell.—*Bristol Paper, March 3.*

Hull and Selby Railway.—This important undertaking is rapidly progressing. The embankment on the west side of the Market Weighton Canal, about one mile in length, is nearly completed. The embankment on the east side of the canal is commenced; the foundations for the flood arches, on the west side of the canal, are excavated, and the sheet piling is finished. The abutment and wing walls of the bridge over the Ouse, on the Selby side, have been raised to the point of the springing course for the iron arches, and the pier piling next to the abutment is driven down. The foundations of the abutments on the Barlby side are excavated, and the piling is commenced.

Sheffield and Rotherham.—Of this railway, the greater proportion of the masonry and bridge work has been completed; and the state of the works, and of the arrangements generally, is such as to leave no doubt in the minds of the directors, that the whole of the line into the town of Rotherham, as well as the connecting branch with the North Midland Railway and Earl Fitzwilliam's collieries at Greasborough, will be opened in August next.

Havre and Rouen Railway.—Letters received from Paris mention that a company had been originated, which it was expected would have the sanction of government, for the formation of a railway from that city to Havre and Rouen. The subscriptions had been nearly completed, and we understand that the shares allotted for distribution in London have also been taken up.

Taff Vale Railway. The directors state, that with regard to the works, they have given priority to the contracts which would necessarily require the longest period for their completion, such as the viaduct over the Taff river and valley at Geedre-y-Coed, the bridges over the Taff and Rhondda, at Melin Griffith and Dewbridge, together with the tunnels at Geedre-y-Coed and Yniscoy. The directors have, in addition to these works, entered into other contracts, including two more bridges over the Taff, the whole of the Merthyr and Melin Griffith embankments, and all the important works upon the main line of railway. Three more contracts have also been advertised, tenders for which were to have been received on the 7th of March. These fifteen contracts comprise the whole of the main line from Merthyr to Cardiff, with the exception of a few miles, the contracts for which are in course of preparation.

Havana Railway.—This great work was promoted and undertaken by the desire and influence of the Superintendent-general of the Royal Finance, in consequence of the great obstacles which a want of good roads was daily opposing to the commercial operations of this emporium of the Western Islands, and of the considerable expenses which the maintenance of the common roads, if ever so good, might occasion in a climate naturally damp, and the soil of which is so very soft and deep. He conceived, therefore, the idea of constructing a railway not inferior in solidity and magnificence to the best in England. The constancy with which his Excellency has persevered in his object, until he saw it accomplished, by removing obstacles and facilitating the necessary resources, is worthy of the highest praise. The whole of the railway intended to the town of Guines will be completed by May, 1838.—*Diario de la Havana.*

York and North Midland Railway.—Out of eight and a half miles from York, the land for seven miles is already purchased. The average price of it for the York station (eight and a half acres) is 335*l.* 14s. per acre, including all claims for compensation, severance, &c., but the remaining sixty acres average only 95*l.* per acre. Six thousand stone blocks have been contracted for, at 4s. each; 7,000 sleepers, at 3s. 4d. each; 300 tons of iron rails, at 11*l.* 10s. per ton; and sixty tons of chairs, at 8*l.* 10s. per ton. Fourteen and a quarter miles of the Leeds and Selby Railway is expected to be completed early in 1839.

The London and Birmingham Railroad.—On Thursday, 15th inst., a number of surveyors, engineers, and gentlemen connected with the London and Birmingham Railroad, proceeded from Euston Grove entrance to Tring, from whence they were to proceed to Denbigh Hall, a further distance on the line of works of seventeen miles, for the purpose of trying the solidity of the road, which will be opened from Euston Grove, St. Pancras, to Denbigh Hall, a total distance of forty-eight and a half miles from London, on Wednesday, the 21st instant. On the Birmingham Line towards London, the distance completed to Rugby is thirty miles. Denbigh Hall is situated four and a half miles from Woburn, and three from Brick-hill.

Grand Caledonian Junction Railway.—In addition to the opinion of Mr. Stephenson, the engineer, relative to the practicability of forming embankments across Morecambe Bay and Duddon Sands, we can now add the united testimony of Captain Beasley and Mr. Haig, two gentlemen who have had much experience in similar undertakings, both in Lincolnshire and in Holland. These gentlemen have just completed a minute examination of the two estuaries in question, and, like Mr. Stephenson, concur in pronouncing the scheme not merely practicable, but easy of accomplishment. This stumbling block, with many, in the way of the formation of the Grand Caledonian Junction Railway, may now be said to be completely removed, and having thus cleared the way, progressive steps have been determined upon. At a meeting of the most influential gentlemen in the neighbourhood, held last week at Gillfoot, the seat of Thomas Hartley, Esq., to deliberate on this important question, it was determined that a public meeting should be held in this town on the 5th of next month, for the purpose of entering into a subscription to defray the cost of a survey from Lancaster to this town, and arranging other matters for carrying the measure into effect.—*Cumberland Pacquet.*

Grand Junction Railway. An accident has occurred upon the line near Preston Brook, by the giving way of part of the tunnel at that point, owing, apparently, to a fault or slip under ground, which caused a pressure upon the brick work that it was not calculated to sustain. The fall took place on the evening of Saturday, but was attended with no worse consequences than the detention of the trains, the passengers in which will have to change carriages, and walk for about 150 yards, until the debris can be removed. The passenger train and mails will be dispatched as usual, but gentlemen's carriages, horses, and goods, cannot be forwarded beyond this point until the communication is restored, to effect which the utmost exertions are being used.—*Liverpool Albion.*

Birmingham Railway.—We regret to learn that about seventy yards of the railway tunnel, at Kilsby, fell in on Monday last. Fortunately the labourers were absent at the time, and no accidents occurred. On Sunday, a railway bridge, called Folly Lane Bridge, near Coventry, also gave way.—*Northampton Mercury.*

Birmingham and Gloucester.—We learn that an arrangement has been made with the Cheltenham and Great Western Union Railway Company, that clauses shall be introduced in their bill now passing in parliament, giving power to the Birmingham and Gloucester Company to make the line between Cheltenham and Gloucester, if the Cheltenham and Great Western Company fail to do so within a given period; and the public are, therefore, now secure of having that important portion of the line formed within a moderate time, and, consequently, the whole line between Birmingham and Gloucester completed.

Great North of England Railway.—The third half-yearly general meeting of this company was held in Darlington, on Tuesday, the 27th of Feb. A full report was read to the meeting of the contracts made, and the progress of the works which had been commenced from the passing of the act, in the month of June, 1837, to December 31, detailing also the manner in which the works are intended to be prosecuted during the present year, and giving tabular statements of the receipts and disbursements to the end of the last year. The principal points embraced in the report were as follows:—That the most strenuous exertions of the company have been directed to putting into execution the line between Darlington and York, so as to open a communication with London and the manufacturing districts at the earliest period possible, and, that as soon as the funds of the company will allow, the line will be continued northwards, so as ultimately to reach Newcastle.—*Tyne Mercury.*

Blackwall Railway.—The detail survey is completed, the line marked out, and drawings preparing for the contracts, which are expected to be ready in June next. The notice to the tenants will be served forthwith. It is intended to carry the viaduct on arches of 28 feet span. Several of the bridges over the roads will be of iron, in the form of the bow-string arch, 70 feet span. It is not intended to have a parapet, but instead, a neat open ornamental iron railing, which will give the viaduct a light and pleasing effect. The whole of the Brunswick Steam Wharf is to be covered with a shed, with a neat ornamental iron roof.

London and Portsmouth Railway.—The Parliamentary plans for this railway have been lodged with the Clerks of the Peace. The line proposed will be that portion of Stephenson's Brighton Railway, between the Southampton Railway, at Wimbledon Common, and Horsham, where it will diverge to the south-west, and pass through or near the towns of Chichester and Arundel. The gradients are very favourable, a distance of forty miles is on a dead level.

Manchester and Birmingham Railway.—That part of the line between Manchester and Stockport is marked out, and the drawing prepared for commencing active operations in June next. It is also intended to apply, next session of Parliament, for extending this railway from Stone to Rugby, thereby saving a very circuitous route, and considerably shortening the distance between London and Manchester. This line looks well on the map; it will, we have no doubt, be a very formidable rival to the Grand Junction Railway.

Midland Counties Railway.—About 1,000 men are employed on the line between Nottingham and Derby, which is expected to be open for traffic in the spring of 1839; and the line between Leicester and Rugby will be finished in the summer of 1840.

The South-Eastern Railway.—The progress of the work in this neighbourhood has been marked by a considerable advance since the alteration of the weather has permitted the workmen to extend their operations, which now indicate a determined perseverance towards the completion of the grand Shakspeare tunnels. The cliff will preserve its elevation undisturbed, 370 feet above the level of the sea. Beyond the Mulberry Tree public-house, an angular face has been given to the cliff for the commencement of the tunnels; each of which, it appears, will be twelve feet wide by thirty feet in height. The chalk and earth excavated by this cutting is enormous; and has been formed into a platform 30 feet above high-water mark, presenting the apparent level of the intended road. Over the line of the tunnels, seven shafts, at a probable distance of 160 yards, have been sunk to a considerable depth; and from the bottom of each of these shafts a gallery will be driven to the face of the cliff—thus opening to the sea, and having a constant supply of light and air. Half way down the slope of the hill, towards the old Folkestone road, an observatory has been erected for the service of the engineers; and on a similar inclination, but nearer to the town, the first of the shafts is sunk. The last of these sinkings, which are eight or ten feet in diameter at the surface, is near the base of the Round Down, where the tunnel will terminate; and from thence the cliffs have been scarped to a ledge, on which it seems the railroad will run towards Lydden Spout, and the Double Cliffs in Eastware Bay.

Proposed Line from Crookhaven to Dublin.—Much attention has lately been attracted in London to a project which is reported to be afloat, for the formation of a line of railroad from Crookhaven to Dublin, as a means of a much more rapid communication with the United States and our West Indian provinces. The substance of the plan consists in a direct line of road from Crookhaven to Cork, and thence to join that of the Dublin and Kilkenny, which has already been formed, and has been proved to have many natural advantages as regards the proximity of materials for its construction, and a most perfect level.

Newcastle and Carlisle Railway.—Messrs. Grahamsley and Co. has entered into a contract with the directors of the Newcastle and Carlisle Railway for the formation of the remainder of the line from Scottswood to Newcastle, to be executed before the end of the present year.—*Liverpool Journal.*

ENGINEERING WORKS.

Ireland.—A new bridge is to be erected at Belfast, on the site of the present Long Bridge. The plans are from Messrs. Woodhouse and Fraser, Civil Engineers. The bridge is to have five arches, each fifty feet span, with ten feet rise from the springing; the first arch to be about one hundred feet from the Antrim bank of the river, so as to allow sufficient space for increasing the width of the present quayage, and securing an easy approach from Chichester-street, High-street, and Ann-street. The roadway between the parapets is to be forty-two feet in width: the inclination of the approaches will not exceed one foot in thirty-five.

Thames Tunnel.—The works are now proceeding with great activity. Since the last irruption the shield has been considerably advanced, and the tunnel has been lengthened fourteen feet. The miners feel great confidence, and for some days past the excavations have proceeded with more than usual rapidity. Two gun-brigs are about to be moored over the bed of the tunnel, where the works are in progress, to prevent any interruption from vessels in the river anchoring over the place. The people on the Rotherhithe and Wapping shores are in anxious expectation of a communication being opened between these two places under the river, and the consequent improvement of property in those parishes, which has much diminished in value since the termination of the war. Should the works of the tunnel advance only in the same ratio as they have done during the last few weeks, low-water mark on the Middlesex shore will be reached by the end of the summer, all danger of another visit from the Thames will be at an end, and the completion of the tunnel will take place in a very short time.

Thames Tunnel.—Another Irruption of the River into the Tunnel.—At half-past six o'clock on Tuesday morning, March 20, the appearance of the ground, and an unusual noise, as if from a rushing of water into a cavity having taken place, the engineer's attention was drawn to the peculiar circumstances, and he therefore anticipated a rush of water. Mr. Mason, one of the assistant engineers, who was then just going on duty, with some active miners, attempted to take means to prevent an irruption, but finding it useless, he thought it necessary to order the workmen to retreat, and which they did in an orderly manner, by the safety-platforms erected by Mr Brunel for the passage of the workmen in case of danger, and they ascended to the top of the shaft without any personal injury having happened to a single individual, although between sixty and seventy persons were in the works at the time. In about a quarter of an hour afterwards, the water gradually filled the tunnel. Active operations were immediately commenced for filling up the aperture in the bed of the river, as a quantity of clay had been already collected near the spot, for the purpose of forming the proposed covering towards the north shore, and which is not yet completed.

NEW CHURCHES.

Church at Staley Bridge, Chester.—The corner stone was laid on the 2nd Feb., with masonic honours, by Lord Viscount Combermere. The church is situated upon a plot of land containing not less than five acres, and most beautifully situated with reference to the delightful scenery of the surrounding country, and will render the church a conspicuous and pleasing land-mark. *The church* will be in that style of architecture which prevailed towards the close of the thirteenth century, as beautifully exemplified in the Cathedrals of Salisbury, Lincoln, and York, and also in Beverley Minster. The leading features of the design are a lofty nave in the centre, lighted from clerestory windows with aisles on the sides, lighted by coupled lancet windows between the buttresses. The tower is placed at the west end of the nave, and is in four stories or compartments in height. In the first story is the west entrance, which consists of a bold recessed doorway. In the second story of the west front is placed a neat two-light window, with elegant tracery. The next story is formed by neat panelling for clock dials on three sides of the tower. The last story is formed by two narrow lancet belfry windows on each face of the tower. Each angle of the tower is flanked by double buttresses; above the latter rise four octagonal turrets with shafts at their angles supporting canopies over their faces, the whole surmounted by lofty pinnacles terminating in appropriate finials, the highest part of which will be eighty-eight feet above the ground line. The east end of the nave projects beyond the ends of the aisles to form the chancel, the external angles being flanked with bold double buttresses, in one unbroken height, having large attached circular shafts at the angles, and terminating in large plain canopies; above these are placed two large octagonal turrets, having a rich corbel table round their upper parts, surmounted by lofty pinnacles terminating in plain nobs as finials. The east end of the nave or chancel is pierced for a neat four-light window, formed of rich and elegant tracery, similar to a part of the window in the east end of Lincoln Cathedral. The chancel is flanked by two small buildings, one of which forms the vestry or robing room, and the other a porch to the east entrance to the church; the east front of these buildings is pierced with small coupled lancet windows. The sides of the aisles are divided by buttresses into five compartments, with double buttresses at the external angles. In each compartment are coupled lancet windows. The upper part of the aisles finishes with a cornice, over which rises the parapet, finishing with a coping. The clerestory is divided into compartments by flat buttresses ranging with those to the aisles, above which is a cornice and parapet similar to what has been described to the aisles. The clerestory windows are in the form of spherical equilateral triangles filled in with neat tracery; the authority for this description of window may be found in the upper part of the aisles to Westminster Abbey, and in the clerestory of Litchfield Cathedral, as well as in a few of our parochial churches in the west of England. The whole of the church is to be built of stone of a very hard and lasting quality, faced with neat hammer-dressed walling, and having tooled ashler dressings to all the doors, windows, &c. The extreme length of the building will be one hundred and two feet, and the width fifty-seven feet. The church is divided into nave and aisles, the latter being separated from the former by five arched compartments on each side, supported on solid octagonal stone piers with moulded capitals, from which spring stone arches that support the clerestory. The west end of the nave is open by a large archway to the interior of the tower. The nave is to have a groined ceiling, with moulded ribs upon all the intersections of the vaulting, stopping upon moulded stone corbels. There are to be galleries in the aisles and at the west end of the nave. The interior will contain sittings for one thousand and six persons, three hundred and sixty of which are free. The greater portion of the free sittings are in pews, and not in open skeleton seats, as is usually the case in the government churches. There is ample room for an organ of adequate size. There is also provision made for warming the building with hot water. It is expected that the church will be completed by March, 1839. The total cost of the building, including architect's commission, &c., will be about 4,100*l.* The architect is R. Tattersall, of Manchester.

Arbroath.—A new church was opened here in January last, built by subscription, and connected with the establishment, designed by Mr Charles Ower, of Dundee, who gained the premium of fifteen guineas, his plan being the best of sixteen that were presented. It contains 1,100 sittings, and cost little more than £2000. The principal part, which is close on the road leading from Arbroath to Dundee, is in the Grecian style. The interior is very commodious, and the whole has given every satisfaction to the subscribers.

The New Church of St Luke, Berwick Street.—The ceremony of laying the first stone of this sacred edifice took place on the 15th instant. The stone was laid with the usual ceremony by Earl de Grey. The expenses of the building are estimated at about 14,000*l.* The sum collected amounts to nearly 12,000*l.*, leaving a deficiency to be supplied by further voluntary subscriptions. The grant from the Church Commissioners is only 2,500*l.* The plan of the building is in the pointed English style, with pinnacles, flying buttresses, and raised roof. Mr. Blore is the architect, and Messrs. Grundy and H. Hartley the builders.—*Morning Post.*

PUBLIC BUILDINGS AND IMPROVEMENTS.

THE ROYAL EXCHANGE.

A Court of Common Council was held on the 8th of *March*, for the purpose of receiving a report from the Royal Exchange and Gresham Committees, on their proceedings. Mr. R. L. Jones brought up the report of the Committee appointed to consider what was best to be done with the Gresham Trust, and to confer with the Mercers' Company as to the views they entertained of it, in consequence of the destruction of the Royal Exchange. The Committee feeling, from the great increase of commerce, and the alterations in the mode of carrying on the trade of the country since the Royal Exchange was built, that the public would expect a new Exchange to be erected upon a more extended scale, with a different arrangement of those parts not required for the general assembly of merchants and others; and that the streets and passages about the Exchange, particularly on the north side, from its contiguity to the Bank of England, should be considerably widened and improved, and that neither the public nor the court would be satisfied if the opportunity afforded by the fire were not taken advantage of, proceeded to consider and agree to the following suggestions to the Mercers' Company.—

"To rebuild the Royal Exchange upon an enlarged scale, and so as to afford increased accommodation to the mercantile interests. To improve the approaches, and to render the building in all respects worthy of the metropolis; for which purpose it would be necessary to take down the whole of the Bank Buildings, and a number of houses between Cornhill and Threadneedle Street, on the eastern side of the present site. That as the new Exchange may be erected for the sum of 150,000*l.*, that sum should be paid by the Corporation of the City of London and the Company of Mercers, in equal proportions, they being reimbursed (after paying the lecturers and other trusts) out of the future surplus monies of the Gresham estates; the Gresham trustees to give up to the public so much of the ground now forming part of the site of the Exchange as shall be required for the public convenience; and in lieu thereof the site of ground on which the proposed Exchange and buildings shall be erected, do become part of the Gresham trust; and as all the outlay beyond the sum of 150,000*l.* will be rendered necessary for the public convenience, and not for the benefit of the Gresham trust, it will be necessary to make an application to the Government for a grant of money sufficient for the purpose, which it is calculated will not exceed 200,000*l.*"

Sunderland.—Arrangements have been made for building an Exchange, together with a news' room and library over, and a museum in the top story; a committee has been appointed for purchasing the ground, and to advertise for architectural plans and designs.

Woolwich Dock Yard.—Messrs. Grissell and Peto has obtained the contract for building an extensive engineers' workshop, &c., to be built by Government near the new basin at Woolwich

Royal Exchange.—It is generally expected that the committee will advertise for competition drawings for the new building.

National Monument.—A meeting has been held and resolutions adopted with the view of erecting, by means of a public subscription, a national monument in a conspicuous part of the metropolis, to the memory of the gallant Earl Nelson, to commemorate his glorious achievements. Sir George Cockburn, Sir Pulteney Malcolm, Sir T. M. Hardy, Sir T. B. Martin, Sir Robert Otway, Sir Charles Adam, Sir Thomas Trowbridge, Sir Wm. Parker, Sir Augustus Clifford, the Hon. Captain Sp[illegible]r, and Sir Ch[illegible] Bulle[illegible] ori[illegible]tors of the design. The Fo[illegible]

Secretary to the Committee is Mr. Charles Davison Scott, son of the late John Scott, Esq., who was secretary to the Admiral. Trafalgar Square is spoken of as an appropriate site.

Kingston.—An addition, with a new front to the north elevation of the Courts, is now erecting under the superintendence of Charles Henman, Esq., Architect, A.I.B.A.

Kingston.—The Corporation have decided upon erecting a New Town Hall in the centre of the Market Place; the design is in the Italian style; the size 58 feet by 45 feet; the lower story is to be faced with Portland stone, ashlar, the cornices and dressings of the upper story to be of Bath stone. The tender of Mr. Trigg, of Kingston, for 3,832*l.* being the lowest, has been accepted. The design for this building was made by, and the superintendence is intrusted to, Charles Henman, Esq., Architect, A.I.B.A.

St. John's, Newfoundland.—The Government advertised for competition drawings and designs for building a new Town-hall and Market-place, offering three premiums of 50*l.*, 30*l.*, and 20*l.* The drawings of the following architects were received, to whom the premiums were awarded:—Mr. Inman, the first premium; Mr. Grellier, the second premium; and Mr. Finden, the third premium.

THE VICTORIA STEAM-SHIP.—CORONER'S INQUEST.

On Monday evening, 19th of March, Mr. C. J. Carttar, the Coroner for Kent, and a respectable jury, assembled at the Mitre Tavern, in Greenwich, to investigate the circumstances attending the deaths of William Thompson, Robert Brock, and Thomas Walker, who were killed by the explosion of a steam-boiler on board the new Hull steam-ship, the Victoria, on Friday, the 16th of March. Thompson died on board the steam-vessel, the others died on board the Dreadnought hospital ship, whither they were taken after the unfortunate accident.

The jury having been sworn, the coroner addressed them at considerable length. They then proceeded to view the three bodies. On their return, Mr. Charles Bell, the commander of the Victoria steam-ship, was called in and examined. He stated, that the new steam ship, of which he was master, was 816 tons burden, old measurement. She may be 1,200 tons, including her engines, and all together He believes her power to be 380 horse. She has two engines. Left Hull on Saturday, the 12th of March, and came to London direct by the aid of her engines. Nothing particular occurred on the voyage except, as is usual in new steam ships, he could not get the speed he wished, owing to the feed pumps being choked by the chips and other substances getting into them which had been left by the carpenters and other persons employed in the construction of the vessel. The ship got into the river without damage. We went direct to the Custom house quay. Arrived thereon Sunday at midnight. Left there again on Thursday last, between one and two o'clock, and proceeded to Blackwall. There were employed four firemen and two coal trimmers. The accident occurred when we were down in Halfway-reach. At the time I was on the starboard paddle box, and the pilot was on the larboard paddle-box. Had a regular pilot on board. Never go up and down the river without one. The first intimation we had of the accident was the noise of the steam issuing from under the paddle box. He saw the steam and smoke coming out of the first engine-room, and a collier-brig at the same time hailed him. The engines did not discontinue working. On ascertaining something was wrong, he jumped on to the top of the cook-house, and snatched off the weight on the safety-valves, which cleared off the steam. He then got into the engine-room and stopped the engines. When he got down to the engine room it was up to his ancles in hot water. * * * *

In the course of an hour and a half witness and Mr. Napier inspected the engine-room to ascertain the cause of the accident. The boiler was then very hot. He caused the fires to be raked out, and went into the flues, having first put on a dress for that purpose. There was nothing to be seen externally, but internally he found that the inner flue had burst, and the back partition, forming the back of the fire, was blown out. The iron bars of the grates were also blown away, and with the steam, scalding water, and fire, forced into the engine room. Witness was of opinion that the cause of the accident was owing to there being not a sufficient quantity of water in the boiler. It was the duty of the two assistant engineers purposely to look after, and report to, the chief engineers. The names of these men are Thompson and Walker, who are both dead. When we left Blackwall on Friday morning, the crew were quite sober.

William Napier examined.—He stated that he was an engineer, residing at Blackwall. The engines were made from his design. There was nothing peculiar in the engines or boilers. The boilers were made by the proprietors at Hull, they were tested to his satisfaction. The boilers were tested at 50lbs. to the square inch. She was intended to be put to 10lbs. per inch, he considers a boiler tested at 30 and put to 10, is safer than any others used in the country He had inspected the boilers since the accident, and on being asked what was the cause of the accident, said the flues of the boilers were pressed down in consequence of its being overheated, and it was from want of water.

It was the unanimous wish of the jury to postpone the verdict until Allen is sufficiently recovered to give some explanation about the matter; they also wished to have some professional and experienced man to inspect the steam ship, in order that they may obtain some further information as to the construction of the engines and boilers.

It was then arranged that Mr. Penn, jun., the engineer, should examine the ship for the purpose stated, and the inquiry was adjourned for a few days.

Adjourned Inquest, March 27th.

The captain was recalled, and the examination then proceeded.—The Victoria (he said) was tried five different times in the Humber; with one exception, they were working ten or eleven hours. The steamer was four times under way, and once she was tried while at anchor On one of these occasions there was an accident, by one of the pistons in the cylinder breaking. There was no difficulty in feeding the boilers with water.

Mr. William Napier, engineer, recalled.—The boilers, as well as the engines, were made from my designs; the boiler is a plain cylinder; the fire is contained under the boiler, and there is an opening at the extremity. He explained that the flues were formed round the boilers; and between the casing of the flues, and the outside of the boilers containing the water, there was a space of two and a half inches at the side, and six inches at the top and bottom. The outside and inside plates are an inch and a quarter thick. I have made similar engines for the Chieftain, which runs to Portugal; they are not quite so large as those in the Victoria, but there is only an inch and a half between the casing of the flues and boilers.

Examined by Mr. Russell, a juror.—In 1835, the Earl Grey steam-vessel exploded on the Clyde; that steamer belonged to me; I sold my premises at Glasgow, and gave up my business, in consequence of the disaster; the boilers in that vessel were not the same as those in the Victoria; the former contained common square boilers, and the Victoria contained circular boilers; they were the best boilers that could possibly be made, and just as I should make again.

By Captain Rowland, the harbour-master, one of the jurors.—I don't know whether the test-cocks are placed at convenient distances from the flooring of the engine-room; I don't know whether there is a steam-gauge to the engine-room; I merely gave the design, and did not at all go into detail.

Coroner.—You say you made the design for the engines and boilers; now, was it not essential that there should be proper valves and cocks for the safety of the vessel?

Witness.—Yes, there should; but the gentlemen for whom I made the design were engineers themselves, and it would have been presumption for me to have dictated to them what they were to do in detail.

By Captain Rowland.—I was told that the Victoria was not loaded over 10 pounds per inch; I did not see it myself; if the safety-valve were enclosed, it would certainly prevent any mischievous person from playing tricks or endangering the lives of the passengers by creating an over-pressure of steam.

By the Coroner.—I am not aware that there are any inaccessible safety-valves. I never heard the difference between high and low pressure defined; my notion always was, that they were either condensing boilers, or not so; it is altogether nonsense to talk about high and low pressure boilers.

Captain Bell recalled. - Before we left Blackwall I saw the pumps put on myself by the sailors, and saw the water pumped into the boilers. The witness then identified the bodies of the five unfortunate men.

Coroner. Can you tell who had the constructing of the engines and boilers?—Captain Bell. A poor unfortunate man named Swift was our chief engineer, and they were made under his superintendence. Swift is since dead; he expired, after two days' illness, of inflammation of the bowels.

Mr. John Penn, jun, examined. I am an engineer, and in pursuance of an order which I received, I have inspected those boilers to ascertain the cause of the accident that has occurred; I consider that the shortness of water in the boiler had the effect of over-heating the plates, and crusting them, thereby allowing the scalding water and steam to escape; I never before saw boilers constructed like them; they are cylindrical boilers with cylindrical flues or water-boxes, or whatever you may call them, in the centre; the water might have boiled over, and by that means have got drawn into the flues, but how low I do not know; the fires in the Victoria are certainly larger for the quantity of water than I have seen in other vessels. I conceive, if there was a good draught, such large fires might be made as to drive the water out of the boilers. The plates of the boilers were much thinner than we see them in the Thames steamers. There are proper feed pumps to the boilers The boilers don't carry so much water as steamers usually do. The water would, therefore, be sooner evaporated than in common ordinary boilers A foot of water in these boilers would be evaporated one-half sooner than in common ones.

Coroner.—Then to what do you attribute the cause of the accident, neglect of the engineers, or the bad construction of the boilers? Mr. Penn.—There must have been neglect, I have not a doubt.

By Mr. Jacobs. - If I were to make boilers for such a vessel as the Victoria, I should allow for 80 inches depth of water. Perhaps, from the top of the flues to the first gauge cock, the boilers might contain ten tons of water. I will not undertake to say that they will not contain eleven tons. I do not think that circular boilers are so strong as the common square boilers. If the engines had been worked at the general pressure of the Thames steamers, of from four to five pounds to the square inch with a square boiler, the accident would not have taken place. I doubt whether water can be kept in these boilers, from the narrow water spaces, and the intense heat of the fires. A skilful engineer would have raked out the fire, or slackened it when he found the water getting below a certain height; I should consider that boilers for such a ship as the Victoria should be 30 feet by 25 feet each, and that would require to be all horizontal surface. The cross examination of this witness was then continued at great length by Mr. Jacobs, who wished to show the proper construction of the boilers; but most of Mr. Penn's answers, that were favourable, were founded on hearsay, and it is impossible to give them in detail, as they alone would occupy two or three columns of our publication. The effect of his answers generally was, that the fires were more than equal to the supply of water in the boilers. The witness, in answer to further questions by the coroner, said, that a circular boiler made of plates half an inch thick, with ten pounds pressure to the inch, would, as he thought, not be safe.

Mr. Jacobs called the following witnesses:—

Mr Andrew Murray:—I am an engineer, and live at Blackwall; I consider that deficiency of water in the boilers was the cause of the accident; there is no difficulty in feeding these boilers; circular boilers are, in my opinion, considerably stronger than square boilers; if the water had boiled over into the cylinder, any fireman who had been on board a steamer before could discover it; these boilers are as strong as any boilers I have seen; up to the first gauge cock the boilers contain 356 cubic feet of water; it would take fifty minutes up the first, one hour and eighteen minutes up to the second, and two hours and four minutes up to the third gauge-cock to generate the water into steam.

Mr. Amherst Hawker Renton deposed. I am assistant to Messrs. Bramah and Robinson, of Pimlico; I consider the accident on board the Victoria arose from want of a proper supply of water; there is no difficulty in feeding the boilers with water.

James Massey, boiler-maker to Messrs Fairlie, of Millwall, gave similar testimony to the foregoing. The boilers were good ones, but perhaps required a little more attention than others.

There being no further evidence, the Coroner proceeded to sum up the whole.

The jury, after consulting for about half an hour, returned into court, and the foreman, addressing the Coroner, said:—It is the unanimous opinion of the jury that the deceased persons came by their deaths in consequence of the bursting of a boiler on board the Victoria steam-ship, of Hull; and the jury wish me to express the high satisfaction they feel at the conduct of Captain Bell, as also of the owners, for the manner in which they have brought up witnesses, and the pains they have taken to fully elicit the truth.

Mr. Jacobs returned thanks on the part of the Company, and said the engineer, Mr. Napier, who had designed the engines and boilers, was a gentleman of great skill and experience.

The proceedings then terminated.

PARLIAMENTARY PROCEEDINGS.

Feb. 26.—*Necropolis Cemetery Bill.*—Read second time.

Tenby Improvement and Harbour Bill.—Read second time.

Great Central Irish Railway.—Petition presented, and referred to Committee on Petitions.

Anti Dry-Rot Company Bill.—"For regulating the sums to be taken for licenses by the Anti Dry-Rot Company, and for vesting the profits thereof in the Company for a limited time," presented, and read first time; to be read second time.

Eastern Counties Railway Bill.—"To amend and enlarge the powers and provisions of the Act relating to the Eastern Counties Railway," presented, and read first time; to be read second time.

Gravesend Pier Bill.—Bill read second time.

Feb. 27.—*Cheltenham and Great Western Union Railway Bill.*—Read second time.

Grand Junction Railway.—Petition reported, and referred to Committee on Standing Orders.

Gravesend Cemetery.—Petition for Bill reported.

Feb. 28.—*Bolton and Preston Railway.*—Petition reported, and referred to Committee on Standing Orders.

March 1.—*Oxford and Great Western Union Railway.*—Petition reported.

Severn Navigation (Nos. 1 and 2).—Petitions for Bills reported.

Midland Counties (Mountsorrel) Railway. Report (27th February) from Select Committee on Standing Orders, read; Bill ordered to be brought in.

Edinburgh and Glasgow Railway.—Report (19th February) from Select Committee on Standing Orders read; Bill ordered to be brought in.

March 2.—*Edinburgh and Glasgow Railway Bill.*—"For making a Railway from Edinburgh to Glasgow, to be called 'The Edinburgh and Glasgow Railway,' with a branch to Falkirk," presented, and read first time; to be read second time.

March 7.—*London and Croydon Railway Bill.*—Read second time.

Isle of Thanet Cemetery.—Petition for Bill reported.

London Grand Junction Railway.—Petition reported, and referred to Committee on Standing Orders.

Bolton and Preston Railway.—Bill ordered to be brought in.

Grand Junction Railway.—Bill ordered to be brought in.

Oxford and Great Western Union Railway Bill.—"For making a Railway from Oxford to join the Great Western Railway near Didcot, with a branch therefrom to Abingdon, to be called 'The Oxford and Great Western Union Railway,'" presented, and read first time; to be read second time.

March 8.—*Manchester, Bolton, and Bury Canal and Railway Bill.*—Read second time, and committed.

Taff Vale Railway.—Petition for Bill reported, and Bill ordered.

Bristol and Exeter Railway.—Petition reported, and referred to Committee on Standing Orders.

Portsmouth Floating Bridge Bill.—"For establishing a Floating Bridge over the Harbour of Portsmouth, from Gosport Beach to Portsmouth Point, with proper approaches thereto," presented, and read first time: to be read second time.

Cookham Bridge Bill.—"For building a Bridge over the River Thames, from Cookham, in the county of Berks, to the opposite shore, in the parish of Woburn, in the county of Bucks," presented, and read first time; to be read second time.

London and Greenwich Railway Bill.—Reported.

March 9.—*Farringdon (London) Street.*—Report (27th February) from Select Committee on Standing Orders read; Bill ordered to be brought in.

Ardrossan Railway.—Petition reported, and referred to Committee on Standing Orders.

March 12, 1838.—*Taw Vale Railway and Dock Bill.*—"For making a Railway from Penhill, in the parish of Fremington, in the county of Devon, to the town of Barnstaple, and for constructing a Dock in the said parish of Fremington, to be called 'The Taw Vale Railway and Dock,'" presented, and read first time; to be read second time.

Garnkirk and Glasgow Railway.—Petition reported, and referred to Committee on Standing Orders.

March 13, 1838.—*Edinburgh and Glasgow Railway Bill.*—Read second time.

Sheffield Improvement Bill.—"For making a new street or thoroughfare, and widening and improving certain other streets or thoroughfares, within the town and borough of Sheffield, in the county of York," presented, and read first time.

Bury (Lancaster) Water-works.—Petition for Bill reported.

Oxford and Great Western Union Railway Bill.—Read second time.

Newtyle and Coupar Angus Railway. Report from Select Committee on Standing Orders read; Bill ordered.

Bolton and Preston Railway Bill.—"For enabling the Bolton and Preston Railway Company to extend and alter the Line of such Railway, and to make Collateral Branches thereto, and for amending and enlarging the powers and provisions of the Act relating thereto," presented, and read first time.

Cheltenham and Great Western Union Railway Bill.—Reported.

March 20.—*Brandling Junction Railway Bill.*—Read second time.

Bristol and Exeter Railway.—Reported, and Bill ordered to be brought in.

March 21.—*Gravesend Cemetery Bill.*—"For establishing a General Cemetery at Gravesend," read first time.

Isle of Thanet Cemetery.—Reported, and Bill ordered to be brought in.

London and Greenwich Railway Bill.—Read third time, and passed.

Church Building Materials.—Return ordered, "of the amount of all Drawbacks allowed on Building Materials used in the erection of Places of Public Worship in Great Britain, from 5th April, 1817, to 5th April, 1837, specifying the amount of allowance made for each edifice."

March 22.—*Deal Pier.*—Reported, and Bill ordered to be brought in.

Birmingham, Bristol, and Thames Junction Railway.—Reported, and Bill ordered to be brought in.

March 26.—*Southampton Pier Bill.*—To amend and enlarge the powers and provisions of an Act for making and maintaining a Pier and other works; read first time.

Severn Navigation (No. 1) *Bill.*—For improving the Navigation of the river Severn, from the Lock at the entrance of the Gloucester and Berkeley Canal to the Bridge over the river Severn, in the city of Worcester; read first time.

Farringdon Street Bill.—For making a new Street from Holborn Bridge, in the City of London, towards Clerkenwell Green; read first time.

London Grand Junction Railway Bill.—To amend and enlarge the powers and provisions of an Act relating to the said Railway; read first time.

Boughrood Bridge Bill.—For building a Bridge over the river Wye, at a place called Boughrood Ferry, in the counties of Brecon and Radnor, and for making convenient approaches thereto; read first time.

London and Croydon Railway (No. 1) *Bill.*—Reported.

Garnkirk and Glasgow Railway Bill.—For altering and amending several Acts relating to the said Railway; read first time.

Birmingham, Bristol, and Thames Junction Railway Bill.—To alter the line of the Birmingham, Bristol, and Thames Junction Railway, and to amend the Act relating thereto; read first time.

Isle of Thanet Cemetery Bill.—For establishing a Cemetery for the interment of the Dead by a Company to be called "The Isle of Thanet Cemetery Company;" read first time.

Taw Vale Railway and Dock Bill.—Read second time.

Deal Pier Bill.—For making and maintaining a Pier or Jetty, and other works; read first time.

Portsmouth Floating Bridge Bill.—Read second time.

Ladykirk and Norham (Tweed) Bridge Bill.—For building a Bridge over the river Tweed; read first time.

St. Philip's (Bristol) Bridge Bill.—For building a Bridge from the parish of Saint Philip and Jacob over the Floating Harbour to the parish of Temple, in the city and county of Bristol; read first time.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 27TH FEBRUARY, AND THE 26TH MARCH, 1838.

Josiah Pearce Hollbrook, of Devonshire Place, Edgeware Road, Gentlemen, for "An Improved Method or Improved Methods of Propelling Vessels."—27th February; 6 months.

John Danforth Greenwood, and Richard Wynne Keene, of the Belvedere Road, Lambeth, Manufacturers, for an "Improvement in the Manufacture of Cement, and in the Application of Cements and other Earthy Substances to the purpose of producing Ornamental Surfaces."—27th February; 6 months.

Hippolyte François De Bouffet Montauban, Colonel of Cavalry, of Sloan Street, Chelsea, and John Carvalho De Medeiros, of Old London Street, Merchant, for "Certain Improvements in the Means of Producing Gas for Illumination, and in Apparatus connected with the Consumption thereof;" communicated by a Foreigner residing Abroad.—28th February; 6 months.

William Westley Richards, of Birmingham, Gunmaker, for an "Improved Primer for Fire arms."—2nd March; 6 months.

Charles Fletcher, of Stroud, in the County of Gloucester, Mechanist, for "Certain Improvements in the Construction of Looms for Weaving."—5th March; 6 months.

William Lewis, of Brunscomb, in the county of Gloucester, and John Ferrabee, of Thrupp Mill, in the same parish, for "Certain Improvements in Machinery for Dressing Woollen and other Cloths or Fabrics requiring such a process."—5th March; 2 months.

Henry Bessemer, of City Terrace, City Road, Engineer, for "Certain Improvements in Machinery or Apparatus for casting printing types, spaces, and quadrats, and the means of breaking off and counting the same."—8th March; 6 months.

William Hale, of Greenwich, Engineer, for "Improvements in Steam Engines, and Apparatus connected therewith, and in Machinery for propelling vessels."—8th March; 6 months.

Morton William Lawrence, of Leman Street, Goodman's Fields, Sugar Refiner, for "Certain Improvements in the process of Concentrating certain Vegetable Juices and Saccharine Solutions."—8th March; 4 months.

John Seaward, of the Canal Iron Works, Poplar, Engineer, for "An Improvement or Improvements in Steam Engines."—10th March; 6 months.

Charles Schroth, of Sablonier's Hotel, Leicester Square, Gentleman, for "Certain Improvements in Preparing, Pressing, and Embossing the surface of Leather. Communicated by a Foreigner residing abroad."—10th March; 6 months.

Thomas Evans, of the Dowlais Iron Works, Agent, for "An Improved Rail for railway purposes, together with the mode of manufacturing and fastening down the same."—10th March; 6 months.

Abraham Parker, of Gower Street, Bedford Square, Surveyor, and Oliver Byrne, of the same place, Professor of Mathematics, for "A new Instrument for Gauging Malt, and also for Gauging the fluid or solid contents of casks and other vessels."—10th March; 6 months.

William Dale, of Marsh Street, Stafford, Turner, for "Certain Improvements in constructing columns, pillars, bed-posts, and other such like articles"—14th March; 6 months.

Thomas Joyce, of Camberwell New-road, Gardener, for "Certain Improved Modes of, and Apparatus for, applying prepared fuel to various culinary and domestic purposes."—15th March; 6 months.

William Horsfield, of Swillington Mills, near Leeds, in the County of York, Corn Miller, for "Certain Improvements in the construction of Mills for grinding Corn."—19th March; 6 months.

Louis Joseph Amant Ramel, of Lisle Street, Leicester Square, Gentleman, for "Improvements in Machinery for excavating and embanking Earth, for the construction of Railways and other Works."—19th March; 6 months.

Robert Lucas Chance, of the Glass Works, Smethwick, Stafford, for "Improvements in the manufacture of Glass. Communicated by a Foreigner residing abroad" 19th March; 6 months.

Duchemin Victor, of Gracechurch Street, Gentleman, for "Improvements in Rotary Engines to be worked by steam or other aeriform fluids. Communicated by a Foreigner resident abroad."—19th March; 6 months.

James Hill, of Haley Bridge, Chester, Cotton Spinner, for "A Certain Apparatus applicable to Machinery, used in the preparation of Cotton, and other fibrous material, for the purpose of Spinning."—19th March; 6 months.

James Lowe, of King Street, Old Kent Road, in the county of Surrey, Mechanic, for "Improvements in propelling Vessels."—24th March; 6 months.

Michael Wheelwright Ivison, of Hailes Street, Edinburgh, Silk Spinner, for "An Improved Method of preparing and spinning silk, wool, flax, and other fibrous substances, and for discharging the gum from Silks, raw and manufactured."—26th March; 6 months.

Julius Oliver, late of Castle Street, Falcon Square, but now of Queen Street, Golden Square, Gentleman, for "A Certain Improvement in the Filters employed in Sugar Refining."—26th March; 6 months.

Auguste Coulon, of Token House Yard, in the City of London, Merchants, for "Improvements applicable to Block Printing; communicated by a Foreigner residing abroad."—26th March; 6 months.

Thomas Oram, of No. 27, East Street, Red Lion Square, Gentleman, for "Improvements in the manufacture of Fuel."—26th March; 6 months.

Charles Hullmandel, of Great Marlborough Street, Westminster, Lithographic Printer, for "A new Mode of preparing certain surfaces for being corroded with acids, in order to produce patterns and designs for the purpose of certain kinds of Printing and Transparencies."—26th March; 6 months.

Charles William Grant, a Captain of the Corps of Bombay Engineers, residing at No. 1, Saint Alban's Place, Westminster, for "Certain improved Methods of Exhibiting Signals for the purpose of communicating intelligence either at sea or on shore."—26th March; 6 months.

FOREIGN INTELLIGENCE.

Number of Buildings erected in New York in the Year 1836 and 1837.—The City Inspector presented his annual report to the Corporation of the number of buildings erected in this city; from which it appears, that during the year 1837, there were erected 840 buildings of all descriptions, being 986 less than were erected in 1836, in which year there were 1826 houses of all sorts erected. The decreased number of dwelling-houses erected, is 242; stores, 686; workshops or manufactories, 35; and stables, 23. Making in all 986 less than the year preceding.

Railways in France.—The following are the lines about to be undertaken by the French Government, according to the measure lately proposed to the Chamber of Deputies:—1. From Paris to the northern frontier, beginning in the Rue Lafayete, Faubourg St. Denis, and passing through St. Denis, Pontoise, Beauvais, Amiene, Arras, Douai, Lille, and Roubaix. A branch will go from Douai to Valenciennes. 2 From Paris to Rouen, forming part of the line to Havre. This road will be the same as that just mentioned as far as Pontoise, where it will branch off, and pass by Gisors, Estrepagny, and Charleval, and will descend by the valley of Andella to Rouen. 3. From Paris to Orleans, forming part of the line to Bordeaux. It will commence at the Boulevard de l'Hopital, and will pass through Corbeil and Etampes. 4. From Marseilles to Avignon, forming part of the line from the former place to Lyons. It will pass by the Valley des Aigaldes, will be tunnelled through the hills that separate the basin of Marseilles from the port of Berre, and will pass along the canal of Arles, by that town, and afterwards by Tarascon to Avignon.

Railroad in Tuscany.—According to letters from Florence of the 4th inst., a committee had been occupied during some time with the establishment of a railroad between that city, Leghorn, and Pisa. The distance between Florence and Leghorn is fifty-four Italian miles. The discovery of a very rich coal mine in Tuscany had encouraged the Grand Duke to undertake the work. The coal necessary for the consumption of the country had heretofore been imported from France

American National Foundry.—A meeting has been called at Richmond, to adopt means to procure the establishment of the National Foundry, proposed by Congress in that city. The Baltimore papers claim the location for their city, as a place peculiarly fitted for such an establishment. New York is quite as good a place as either; our position on the seaboard makes the facilities of communication with every part of the Union greater than those of any other city. This is a consideration of importance in case of an emergency that would require the shipment of heavy ordnance.—*New York Express.*

It is rumoured, says the *Temps*, that a subscription, at the head of which the King has desired his name to be placed, is forming, for the erection of a monument opposite that of the Belgian Lion, on the plain of Waterloo, to the memory of the brave men of the French army who fell in that great battle. Marshal Gerard is named as one of the committee, and the King of the Belgians is said to have assented to the project.

America.—Utica and Syracuse Railroad.—The work on this road has been commenced. The whole is under contract, and is estimated to cost about 600,000 dollars. The route is said to be a very favourable one—requiring but little excavation and grading. The road will probably be completed in the summer of next year—which will be an extension of sixty miles of railroad communication towards Buffalo.—*New York Daily Express.*

Destruction of the Bowery Theatre.—A little after 2 o'clock on Sunday morning, the 18th ult., the beautiful edifice, erected but little more than a year since, known as the Bowery Theatre, New York, was entirely destroyed by fire. The scenery, machinery and stage property being all highly combustible, were soon consumed, and at about 3 o'clock the roof fell in, sending aloft a mass of cinders which flew far and wide, and burying beneath it all that remained of the ill-starred Bowery Theatre. The wardrobe, scenery, and other properties, were valued at about 60,000 dollars, upon which there was no insurance. Insurance to the amount of 35,000 dollars had been effected upon the building, which, it is supposed, will not cover one-half of the whole actual loss. This is the third building, devoted to theatrical purposes and erected upon this spot, that has been burned within ten years. The first edifice was burned in May, 1828, the second in September, 1836, and the third on February 18, 1838.

MISCELLANEA.

Height of Waves.—Mr. Pentland writes from Valparaiso, that during the most violent storms which the frigate *Stag* encountered in the Pacific Ocean, the waves never rose more than twenty feet above the level of the sea. The greatest height the waves attained above the deck of the frigate, which had been observed and measured, did not exceed eighteen feet.

New Alloy of Zinc and Copper.—A committee of the French Academy of Sciences is engaged in investigating a new alloy of zinc and copper, which is said to possess qualities which fit it for extensive use in the arts and manufactures. Its cost will be little more than that of zinc. The pure metal of zinc oxydizes with great facility, which renders it unfit for a multitude of uses; the alloy, however, is oxydized with great difficulty. It will resist, for example, sulphuric acid of twenty degrees of concentration. Hence it may be used for mineral waters, for pipes and tubes through which acid liquids flow, and, in navigation, for the sheathing of vessels. The composition of the alloy depends on the uses to which it is applied. If it is applied in circumstances where zinc is commonly used, the inventor mixes with a great proportion of the latter metal a small quantity of tin and lead—an addition which does not augment the cost of the alloy more than a farthing a pound. The alloy which is used for boilers, gutters of houses, &c., contains no lead; but still, like the other, resists the sulphuric acid of twenty degrees concentration.—*Monthly Chronicle.*

Stoppage of the Canals.—The loss to the farming and mercantile interest of this part of the country, caused by the stoppage of the canals, can scarcely be estimated, and affords one of the strongest motives that can be adduced for extending the railway system into the rural districts. Whilst Lincolnshire has been losing its thousands, Ireland and the country connected with the railways of Liverpool and Manchester have enjoyed all the facilities of reaching the markets by means of the railways, and both flour and wheat have been abundantly supplied at remunerating prices: whilst there has been a general stagnation on the eastern side of the island. If this does not impel the landed interest to co-operate in the formation of railways, they must expect declining markets in those parts that are without the advantages that other parts have secured, and the current of trade and consumption to flow from remote districts even into the markets which heretofore have been considered specially to depend on Lincolnshire.—*Hull Observer.*

Crystallization.—M. Gaudin, who has been *making* minerals, has submitted to the Academy of Sciences more stalactites of carbonate of lime, which have been produced in a month: he has also succeeded in making microscopic glasses of melted rock crystal, which answer perfectly well, and magnify 250 times.

Electro Magnetism.—Mr. Cook made an interesting exhibition of an electro-magnetic machine, acting on the principle of Davenport's patent, now exhibiting in Barclay Street. The whole apparatus is of the most simple construction, consisting of two sets of magnets, one revolving within the other. The external magnets being excited by the fluid generated by the action of an ordinary galvanic battery, while the polarity of each magnet constantly and regularly changing, a perfectly uniform motion is communicated to the cylinder, which may be increased indefinitely as additional force is applied. The machine is thirty inches in diameter, and contains seventy-eight magnets, each weighing four pounds. The machine, in full operation, made eighty revolutions per minute—considerably more than can be obtained by the force of one man. Mr. Cook states that the power of the machine may be greatly increased by adding to the number of magnets, without enlarging the battery, and he intends to do so immediately, and apply the power, by way of experiment, to the working of a printing press. There are, of course, many imperfections in this machine, which is not yet complete, but they are obviously the result of mechanical arrangement, rather than of defect in the principle. The inventor of the mode of applying this newly-discovered power is quite sanguine of its complete success, and of ultimately superseding the use of steam in locomotion and propelling machinery. Another machine, to be worked by eight pairs of large magnets, of 100 pounds each, made by Mr. Davenport, was also shown, with three pairs of the magnets in motion, which performed well.—*New York Paper.*

Reciprocal Liberality.—By a recent arrangement, all English architects travelling for improvement in Saxony and the territory of the Hanse Towns, are to be admitted freely to view all the public buildings, &c., without expense—on the condition which has been acceded to by our own Government, that the architects of those countries shall enjoy a similar privilege here. Negotiations are in progress for the extension of this give-and-take system to other parts of the continent.—*Mech. Mag.*

Pompey's Pillar.—On the sixth of September last it blew a heavy gale at Alexandria from the westward, which raised such dense clouds of sand as to render distant objects totally invisible. But in the interval between the squalls, to the surprise of the officers of the Egyptian squadron and the inhabitants of the town, the colours of England were observed floating on the summit of Pompey's pillar, while a discharge of musketry was heard from the same elevated situation. On inquiry, it appeared that a party of officers belonging to her Britannic Majesty's steam-vessel Hermes, had, by means of a huge kite, contrived to get a piece of twine across the top of the pillar, to which was attached a small cord, and ultimately a larger one was hauled up, and a ladder was expeditiously formed. A party of ten then ascended the pillar and seated themselves on the summit, with the Union Jack planted in the centre. Here they drank to the health of Her Majesty Queen Victoria of England, with three times three, and fired a royal salute. The prospect of the surrounding sea and country from this elevation is described by one of the officers, who was of this intrepid party, as very fine; but the tremulous motion of the pillar was so great as to shake out the contents of a wine glass!—*Malta Gazette.*

New Day and Night Telegraph.—A telegraph of this nature is engaging the attention of the maritime interest. It is intended to answer the purposes of signalizing between the shore and ships in the offing, and to prevent steam-vessels coming into collision. It is also applicable to railways, and may be made available for coast-guard stations, for the revenue cutters and boats belonging to the coast-guard, and for signalizing for government ships. The night signals are completed by means of four figures; and the properties of the telegraph are, that, in whatever position, it will show a full front with a brilliant light; and although more figures will be required for the day signals, it will yet show a full front to the object communicated with. It is worked on a plan independent of lines; it is of a very simple arrangement, and appears applicable to all the purposes for which it is intended. The inventor is Capt. Smith, R.N., the officer who first called the attention of government to the important subject of appointing emigrant agents to protect and assist emigrants, and see that they were sent out in sea-worthy vessels

NOTICES TO CORRESPONDENTS.

We have been compelled to postpone several communications until next month, when we will endeavour to bring up the arrears.

C. L. O. must excuse us for not inserting his communication for the present, we should like to hear from him on a more *practical* subject.

Architectus is informed, in answer to his communication, that we have so arranged the Advertisements that they shall not appear in the Work when bound up; such pages as are *not* figured are then to be cancelled. The first volume we propose to conclude with the next December number.

I. I. will find a Notice of the Society, which we hope will be satisfactory.

BRIDGE ACROSS THE RIVER TEES.

Fig. 1.—ELEVATION.

Span of Arch 150 feet. Rise or versed sine 16 feet.

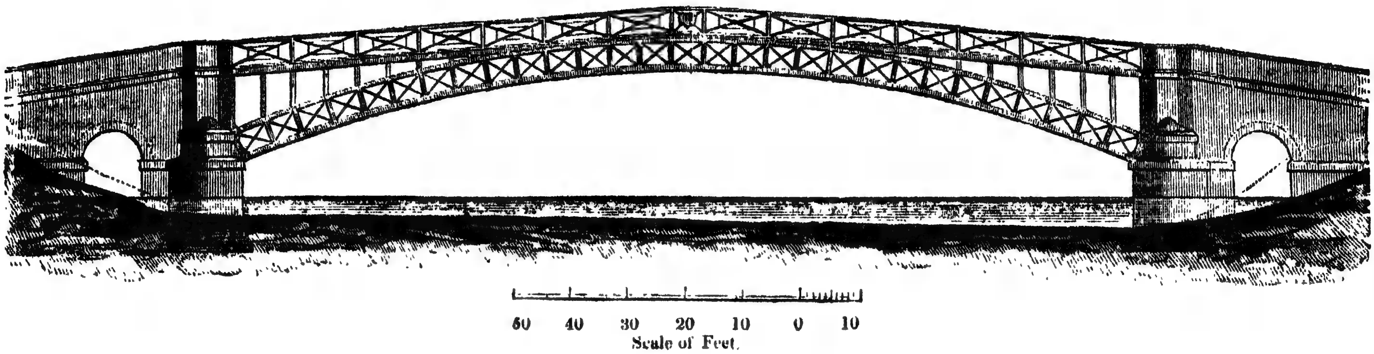


Fig. 2.—Section of Bridge and Elevation of Abutment Pier.

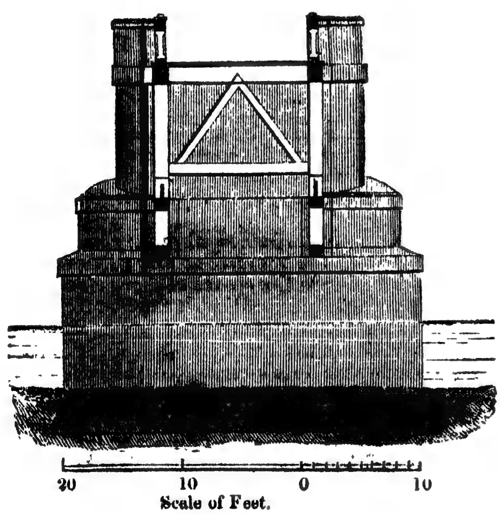

Fig. 3.—Section of Abutment and part of the Bridge.

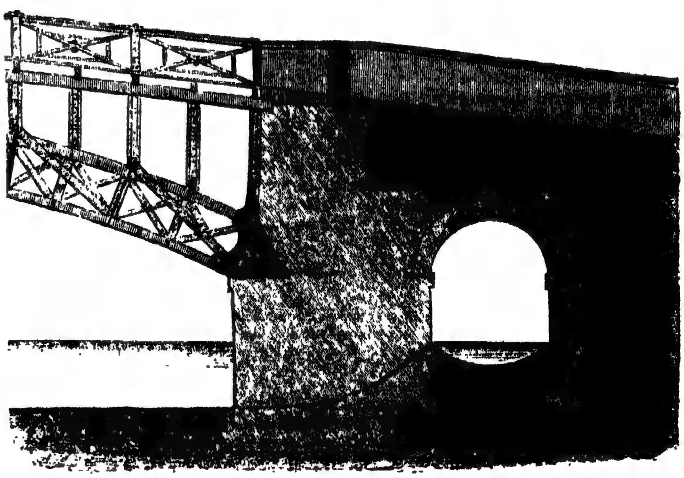

Fig. 4.—Plan of the Entrance to the Bridge and part of the Bridge.

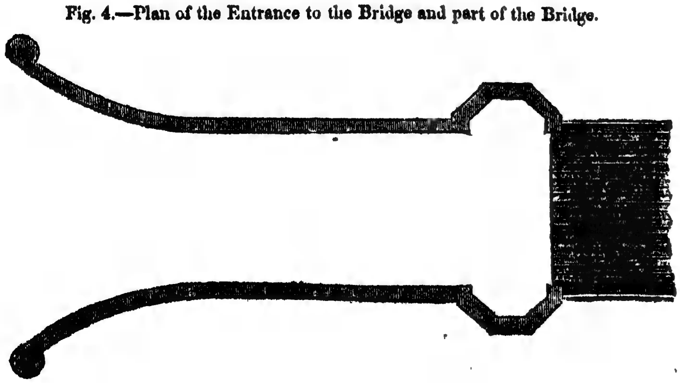

Fig. 5.—Plan of Abutment and Timbers of the Bridge.

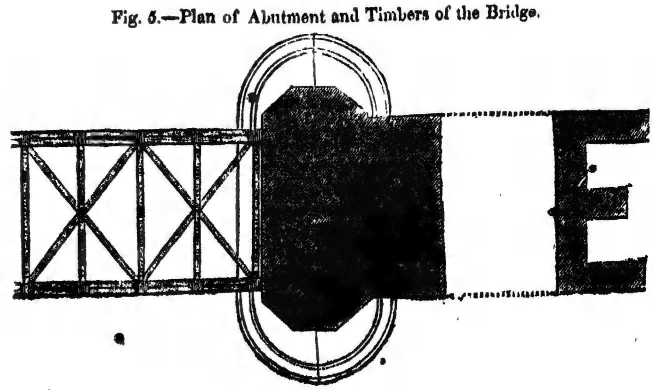


BRIDGE ACROSS THE RIVER TEES, IN THE PARISH OF SOCKBURN, UNITING THE COUNTIES OF YORK AND DURHAM.

This bridge is now completed: and as it is a work of considerable importance, possessing features of interest and of novelty, we are happy to be enabled to give our readers a full description, accompanied with drawings. It has been built at the expense of Henry Collingwood Blackett, Esq., with the view of affording himself and his tenantry more easy access to the main road from York to Newcastle, distant about three miles, through the village of Smeaton: and also to the towns of Northallerton, Yarm, and Stockton-upon-Tees, and the different villages in the neighbourhood. The previous means of communication for horses and carriages was by a ford, passable only in dry weather. The course of the river having high ground on each side, a sudden and heavy rain has been known to swell the stream to the depth of fourteen feet in a few hours. The current being consequently very strong, the floods have been known to bear away trees of large dimensions torn up from their roots, where any wood plantation has reached the river banks. Hence the necessity of having a bridge the entire span of the river; as any intermediate support of piling for a superstructure would have been attended with some risk as to its stability, both from the floods above alluded to, and from the floating ice brought down the stream upon the breaking up of a frost. Piers of masonry, for any number of arches across the river, would in like manner have been objectionable, from the obstruction they would have caused in the channel, by contracting the water-way.

This bridge has been built from the designs and under the direction of Mr. William Hambley, of Park-street, Islington, London; and the execution of the works intrusted to Mr. Richard Golosbro, carpenter, of Harworth, near Darlington, to whose judicious care and management in the construction the highest praise is justly due. The structure has been opened for all the purposes intended, since December last; though the railing to the roadway was not completed till the 24th of March.

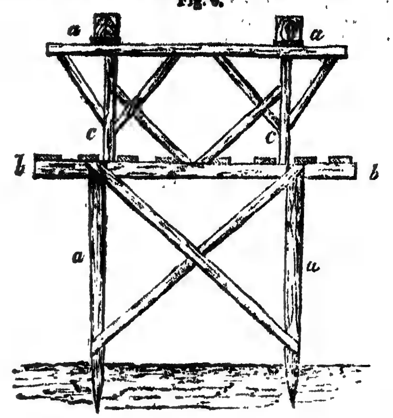
The main arch is composed of a series of framework in wood, forming an arch of 150 feet span, the versed sine or rise 16 feet; with a semicircular stone arch at each end, of 10 feet span; making together with the piers and wing walls, a length of 250 feet. The clear width in the roadway is thirteen feet.

The piers and arches at each end, with the abutments, are executed with stone quarried from the bed of the river, laid in equal courses, and tooled fair on the face. The material is a red sandstone, soft and free to work when first quarried, but which becomes hardened from exposure to the air. The larger masses have only a casing of masonry, the internal parts being filled in with a concrete composed of gravel (also from the bed of the river) and pounded stone lime, mixed in the proportions of six of gravel to one of lime. The casing of masonry was raised about two feet, and then a layer of concrete filled in to the same level; the masonry then proceeded another step, and received again a layer of concrete: the alternate heights were in different thicknesses, one being about one foot six inches, and the other two feet six inches, in order that a bond might be made with the stone and the concrete.

In the autumn of 1836, preparations were made and the work commenced, by laying the foundations of the stone piers. That on the Yorkshire side of the river was raised several feet above the bed, and a rough stage formed across the river to the level of the springing of the main arch. This stage was composed of larch wood piles, or other coarse timber of English growth, with bearers of fir, and the planking of the proposed roadway of the bridge laid upon them. It was intended as a means of fixing the timbers of the arched ribs across the river, and served for some time the purpose of a temporary bridge. In consequence of the severity of the winter, and the great floods, the works were suspended. The frost breaking up in February, 1837, the ice floating down the river carried away a portion of the stage; in fact, several of the piles were nearly cut asunder by the ice. This unfortunately gave rise to a report that the bridge had been carried away; whereas not a single piece of timber of the intended structure had been prepared for the purpose.

In the following May the works were resumed, and proceeded through the last summer and winter. By the end of June the masonry at each end was ready to receive the cast-iron seating plates of the wood arch, and the stone arches turned. In the meantime the curvature of the ribs had been set out upon a platform, and the carpenters proceeded with the framework. This being ready by the month of August, preparations were made for laying the seating plates within the masonry, and fixing the arched ribs from pier to pier. This was accomplished from the stage before alluded to, the injured parts having been restored. It was executed as shown by the sketch—a a,

Fig. 6.



larch, or other wood piles, driven about fifteen feet apart in the length and width of the bridge; *b*, fir bearer, upon which the proposed planking was laid; from this stage were raised the standards *c c*, to such heights as the curvature of the ribs required. As they proceeded from the springing of the arch towards the centre, these were braced, and three-inch planks laid flat on the top of the standards. On these the wood ribs *d d* were laid, with a sufficient space for two wedges over each support upon the planks. This stage and the carriage remained till the two ribs with the radiating timbers and diagonal braces were fixed. The wedges were then struck, and the weight of the ribs thrown upon their seatings and head joints, the latter having two thicknesses of lead, seven pounds to the foot. The stage with the carriage was then cleared away. The other part of the work was executed by forming a stage with plank upon the two upper ribs.

The circular ribs are formed in two thicknesses of timber, each twelve inches by six inches, and bolted together with seven-eighths round bolts; the heading joints are broken about every ten feet in length. Upon the ribs are raised the vertical timbers, which are ten inches by twelve inches; these are framed with the upper ribs, and passed through the longitudinal roadway beams (which are also in two thicknesses, twelve inches by six inches, and bolted together), and halved and bolted to these and the transverse beams of the roadway. The parts of the vertical timbers above the roadway are reduced in size, and formed into a series of trusses with the braces throughout the length of the bridge, and secured by stirrup-irons, bolts, and wedges, to the main ribs. Stretching beams or braces are framed across to each of the ribs, and secured by end grain bolts to the ribs. Upon these are placed diagonal braces to the centre of the transverse beams of the roadway; and with the latter are framed the diagonal and horizontal braces of the roadway, upon which the planks are laid with a slight coating of gravel.

In the construction of the framework, a very important consideration suggested itself, as to the removal of any part of the timbers which might become defective in the course of time. This has been kept in view, so that any single piece of timber may be removed without having recourse to shoring, or any other temporary means of support.

The durability of the work was also a subject to be carefully kept in view: with reference to which object, the bridge was constructed with the very best Memel timber Kyanized; the joints coated with tar, and the whole well painted.

The quantity of timber in the framework and roadway is about 4,250 cubic feet; and the expense of the whole bridge about £1,200.

REVIEWS.

Practical Essay on Steam Engine Boilers. By R. Armstrong, Civil Engineer. Manchester.

The third and concluding Part of this really practical and useful work is before us. Chapter IV. is occupied, in the first place, with a dissertation upon the action of sand, &c., within a boiler, which is treated in a very pretty manner. The only difficulty we have in comprehending the advantages so earnestly dwelt upon in *this chapter, in favour* of Mr. Scott's collectors, or generators, is the very decidedly *unfavourable* opinion given by the author, of the same system in Part 2, in which he stated that the pots, or collectors, although found useful in one sense, were generally abandoned in consequence of the difficulty of cleaning the boiler in which they were placed, in the usual manner, viz., by hand.

The author's improvement upon Mr. Scott's apparatus is thus dwelt upon:—

Now the circumstances under which a steam-engine boiler is placed, necessarily include a great variation in the state of ebullition of the water, it being most violent when the demand for steam is the greatest, and at such times we may conclude, that the superabundant carbonic acid, as well as the atmospheric air, and all other gases that admit of expulsion by boiling, are present

to a much smaller amount than at any other time,—of course the carbonate of lime is then deposited, and obeys the same laws as any insoluble deposit; consequently it accumulates in the sediment vessel or collector, precisely for the same reason as does the argillaceous and other sedimentary matter, as already explained. In fact, the carbonate of lime, although called a *chemical* deposit, is, at the time of its deposition, as much a *mechanical* one, as that of any insoluble matter, and it becomes so the instant it separates from the water in a solid state; but being an impalpable powder, it requires a collecting vessel more perfectly free from agitation, than the coarser mechanical deposits. The principal difficulty is to retain it in the sediment vessel; this object, however, is very well attained by an apparatus which I contrived and brought into use in 1829; it was made by forming the upper part of the collectors of a hopper shape, to which was attached a lower part or receiver, made perfectly water-tight;—from this receiver a pipe was carried to the outside of the boiler, through which, by means of a valve, the contents of the receiver were discharged as often as necessary.

The object of the above contrivance, was to combine the principles of Maudsley and Field's patent of 1824, with that of Mr. Scott's of 1827, with the intention of making it useful for marine or steam-packet boilers. Now the proper use of this discharging apparatus is essential to the complete attainment of the object of keeping the boiler perfectly free from *incrustations of carbonate of lime*; for if this deposit is allowed to remain in the receiver too long, it is liable to be in part re-dissolved by any increase in the quantity of *free carbonic acid*, only to be again re-deposited; but which, of course, may be prevented by *blowing it out frequently* along with the rest of the sediment.

That this apparatus is not yet fully adopted in steam packets, arises from the same causes which so long delayed its general use in factories. In the few trials which it has already had in the City of Dublin Company's packet the "Shamrock," its perfect efficacy has been proved—so far as can be expected of any new invention, when there has not been sufficient experience to perfect all its details. The apparatus was proved to collect the thick brine as it became concentrated by the evaporation of the sea water, and while being blown out, it partly crystallized, or assumed the state of a fine salt, with just as much water as was sufficient to hold it in a semifluid state, and which was essential to its discharge. The discharge is effected by the pressure of the steam acting suddenly upon the contents of the receiver, and blowing them through a pipe fixed in the side of the vessel. Through this pipe large substances can be sent with great force, after the manner of a steam-gun.

* * * * * *

A modification of Mr. Scott's patent collectors, somewhat similar to those already described, with the addition of an agitator, which is worked by a small shaft or spindle passing through a stuffing box to the outside of the boiler, answers the above purpose very effectually, as it admits of the use of potatoes, or any other treatment to which the boiler may be subjected for the sulphate of lime, without the liability of the apparatus becoming clogged up.

The openings into the collecting vessels of this apparatus, or self-cleansing machine, are made sufficiently small to enable it to catch *nearly all the carbonate of lime*, while it also catches the *whole* of the other sediment; which is discharged from time to time, without any interruption to the working of either the boiler or engine.

The above apparatus, in its present improved state, is called a *machine*, although it is not exactly a machine in the ordinary acceptation of the word, on account of the extreme simplicity of its construction, there being neither wheel nor pinion about it, nor indeed any of the other mechanical powers, unless the lever of the handle may be so called, which puts the discharging apparatus in action. Moreover, unlike all other machines, its most important functions are performed while standing still. It is never put into action but two or three times in the course of a day, for discharging or "blowing out," and that for less than half a minute each time, according to the quantity of sediment which it has collected; consequently, it is not very liable to wear out, besides rendering its first cost comparatively small.

The author of this work, by an arrangement with the patentee, made and fixed up several hundred of these boiler cleansing machines in this district, the boilers to which they are attached not having required any other mode of cleaning out for some years. There are one hundred and seventy of these machines now in use in Manchester alone, so that any considerations in the construction of a boiler, with a view to the necessity of a man going inside to clean it out, may be safely discarded.

The evidence contained in the last paragraph alone is valuable, and it can scarcely need our recommendation that proprietors of steam boilers would do well to avail themselves of this contrivance; in fact, if it prove so highly effective as here stated, it would be very easy to apply it to a locomotive, by placing the collectors before and behind the fire-box, and connecting them by pipes, so as to blow out the whole at one operation.

The following extract expresses the author's opinion of the cause of explosions:—

Most people are aware of the rage for building very large factory chimneys, during the last few years, and as they are usually built much larger at first than the wants of the factory require, there is always a surplus draught, which, by setting the main damper wide open, can be taken advantage of to any extent, and in many cases to cause an intensity of heat almost equal to that in a blast furnace. Where this surplus draught is easily available, the fireman has little to do but open his dampers, and the steam is got up in one half the time that it required formerly.

Whether the boiler is dirty, or has too much water in it, one consequence is the same, under ordinary circumstances, namely, a greater length of time is required for getting up the steam, and this necessarily requires the earlier attendance of the fireman. Now the fireman is not generally summoned at a certain hour like the regular mill hands, and if he can only contrive to get up the steam in sufficient time for the engine starting at the appointed minute, there is seldom any fault found; therefore any expedient which will enable him to prolong the period of his commencing work is not likely to be neglected, and such an expedient he has wherever there is a good draught.

It unfortunately happens that, in this matter, the interests of the manufacturer and those of humanity do not agree; for it has been incontestably proved, that a strong draught is extremely favourable for saving fuel, as may be judged from the fact, that the time for getting up the steam has been in some instances reduced from upwards of an hour to twenty or twenty-five minutes, and although the saving of coal has not been in anything like that proportion, yet it has been very considerable.

Under similar circumstances to those just mentioned, there can be no doubt that a portion of the boiler bottom occasionally becomes nearly red hot, although this condition appears extremely inconsistent with the supposition that it is at the same time covered with water; yet I have been compelled to adopt this conclusion, from having had ocular demonstration of its possibility, as well as other reasons. I had frequently heard the fact stated by intelligent enginemen, and had more than once been called to witness it, although even then inclined to consider it a mistake, owing to the difficulty of ascertaining it clearly; for a slight approach to the incandescent state must be nearly invisible, owing to the strong glare of light from the furnace directly beneath, while any degree of heat much higher would be sure to weaken the iron so much as to cause the boiler bottom to give way.

In one instance, however, the rivet heads appeared to be approaching to a dull red, and I immediately took care to satisfy myself that sufficient water was in the boiler. On returning to the furnace, my doubts were at once removed, on seeing a circular space, of six or eight inches in diameter, in one of the plates over the middle of the fire "drawn down" into a spherical segment, or swelling, of about two inches in depth, something similar in appearance to those formed on a smaller scale in glass-blowing; but its further protrusion had evidently been checked by the sudden opening of the fire-door, which, no doubt, prevented any serious consequence at the time. The boiler was a cylinder, of nearly six feet in diameter, and the pressure was about nine or ten pounds to the square inch. The occurrence took place just at the moment of the steam being sufficient to blow away at the safety valve, and a few minutes before the engine started. For a few days afterwards, *this segmental protuberance was observed to increase* gradually to a hemispherical shape, of three or four inches in depth, when it *burst without doing any further damage than putting out the fire.*

The probability of boiler bottoms sometimes approaching a red heat, receives a *corroborative proof on examination of the iron plates*, in many cases, where the boilers have bulged out in the manner we have been describing, and which exhibit an appearance, well known to boiler-makers by a peculiar colour in the iron surrounding the part which has been red hot.

Whenever a boiler bottom is seen in this state, of course the only method of avoiding danger is to slack the fire immediately, by opening the fire-doors. But it frequently happens that the fireman fancies the boiler to be empty, and, if he have an opportunity, he immediately lets into it a quantity of water, when the consequence uniformly is, that the boiler bursts instantly.

From the premises we have laid down, it may fairly be concluded, that the pressure of the steam, suddenly generated at the moment of explosion, will bear some near proportion to the area of the hole or aperture; and as the actual pressure exerted the instant after the aperture is formed must be equal to the previous pressure drawn into, or multiplied by, that area, we may assume the square of the area, or fourth power of the diameter of the aperture, as representing a good approximation to the proportional force exerted—the reaction of this force propelling the boiler in a direction opposite to the aperture.

Hence, we have a reason why the bursting of a comparatively small hole in a boiler bottom produces such a very feeble effect, as compared to one of six or eight times its diameter. For if the force of explosion in any given case be called 1, then the force in any other case, producing an aperture of double the diameter of the former (other circumstances being the same), will be represented by $2^4=16$; if of

3 times the diameter, it will be		$3^4=81$
4 times	"	$4^4=256$
6 times	"	$6^4=1296$
8 times	"	$8^4=4096$

Some persons who have paid a good deal of attention to the circumstances connected with explosions, have doubted the possibility of steam being generated in sufficient quantity so suddenly as my explanation would seem to require: this, of course, is a matter which can only be proved by direct experiment, and such an experiment is yet a desideratum in this country. At present we have only one of the American experiments which throws any light upon this part of the subject; the repeating of this experiment on a large scale is highly desirable, although it would be attended with some danger and not a little expense. In the one alluded to, water was purposely injected into the boiler when the bottom was *red-hot*, by which means the steam was raised from one up to *twelve* atmospheres (180 pounds per square inch) *in one minute*, when the boiler exploded with violence. The American report states, that in the violence of the effect, the experiment was not carried so far as it might have been, from not throwing in a sufficient quantity of

water; consequently, the metal was not *cooled down to the "point of maximum vaporisation"* when the explosion took place, otherwise the pressure, as indicated by the thermometer the moment before the explosion, might have reached about forty atmospheres in the same time.

The above-mentioned experiment supplies an illustration of the general inutility of safety valves in case of sudden explosion. The safety valve is, in fact, a perfectly useless appendage to a low pressure boiler provided with the ordinary feed pipe in common use in factories; more especially when the buoy rod is made to pass through an open pipe of the same height as the feed cistern, instead of working through a stuffing box. This well-known feeding apparatus is an infallible preventive against the steam getting *(gradually)* too high, as well as against the water getting too low; the latter being by far the most dangerous predicament of the two, and a frequent cause of explosion.

We have extracted thus largely, because we consider the view of the subject taken by the author deserving much consideration; and although we agree that in a *common boiler* the water getting too low is the proximate cause of the boiler attaining a dangerous temperature, it is the *large quantity* of water still in the boiler, when some part is heated above, or at, the point of maximum evaporation, which is the reason of the prodigious and sudden creation of steam causing the explosion. If a boiler of the ordinary construction, instead of being heated up to 220 degrees, with a considerable load of water covering the surfaces, were heated to 500 degrees, and the same surfaces wetted or suddenly covered with a *large quantity* of water, the generation of steam would be so prodigious that nothing could withstand it. Therefore, this being the case, an ordinary marine boiler is the most dangerous of all possible contrivances of the kind. The upper part of the flues are covered with water to the depth of only a few inches; should this quantity, from whatever cause, be evaporated, the fire would, in the course of a few seconds, heat the surfaces up to 500 degrees, and beyond it; this would (supposing the upper surfaces dry) overheat the steam, then the steam would become a generator, by communicating its heat to the water remaining in the boiler; and in proportion as the quantity of water decreased, the water would become agitated, thrown in foam upon the heated plates, and thus create a generation so rapid, as fully to account for any explosions which may result; and this was unquestionably the cause of the late catastrophe to the "Victoria" steamer, in the Thames.

We do not agree with the author that the feed head is the best safety valve. In any case its efficacy is limited, like that of the safety valve, to the size of the orifice; and it has this very great disadvantage, that before the steam can escape, all the water above the level of the bottom of the pipe, which is perhaps six inches from the bottom of the boiler, must be driven out. Its greatest recommendation is driving out the explosive matter or water; but we apprehend, that in the case of the boiler becoming overheated, as at present constructed, the feed head would allow the water to pass so slowly, as to be of very small service; and if the pipe were made larger, the heated and exposed column of water would be the objection.

We must also except against the expression "that the interests of the manufacturer and those of humanity do not agree," in respect of the construction of large chimneys in order to increase the draught. If the interests of the manufacturer are thus served by economy of fuel, both in quantity and quality, so are those of humanity by the consequent reduction of price in necessary and useful commodities. Again, if the interests of humanity require that this powerful machinery should not by neglect be blown up, to the destruction of human life; no less do those of the manufacturer, that it should not be carelessly destroyed at the expense of his capital. It is, in fact, the interests of the manufacturer, and the supposed interests of a lazy and unpunctual engine-man, that do not agree. And we think Mr. Armstrong will agree with us, that it is desirable rather to make the engine-man punctual, by stricter supervision, than to give up the advantage of the increased draught obtained by the large chimneys. Nothing is easier than to put up in the engine-house a silent witness, to record the time at which the engine-man arrived, and to call him to account for every minute that he was too late.

Chapter V. "General principles in the construction of boilers, and a description of the various kinds of boilers in general use in the manufacturing districts," is exceedingly interesting; but our extracts have been already so ample, that we must refer our readers to the work itself. In conclusion, we cannot but express the very high opinion we entertain in favour of the work, and have no doubt it will be found exceedingly useful, and will be very extensively read by the public.

Gothic Architecture—Penny Cyclopædia, Part 63.

THIS, and the other architectural articles hitherto published in the Penny Cyclopædia—viz. "Civil Architecture," "Design (Architectural)," "Egyptian Architecture," &c., although unavoidably limited in extent, are so far from being superficial compilations, that at the same time their subjects are treated as perspicuously and popularly as they admit, more information may be gained from them than from longer treatises of the same kind in other publications. In saying this, we do not express our own opinion alone, but that of many others; for we have heard it remarked of the article on "Civil Architecture," that it gives a far more distinct insight into the principles and character of the Grecian orders, than is to be obtained from almost any other account of them. To this may be added, that reference being made in it to the best specimens of the different orders in buildings about town, not only is the learner's memory greatly assisted, but an additional interest excited. The article on "Design," explaining the nature of plans, sections, and geometrical drawings, has the further advantage of being altogether novel; for before they had only been briefly defined under their respective terms, and that generally so unsatisfactorily as to be hardly intelligible, except to those who, least of all, needed any information relative to them; whereas, not only are their various purposes fully explained, but in such a way as forcibly to point out the very great interest connected with the accurate investigation of such drawings.

This last published article, on "Gothic architecture," is treated with equal ability, and does all that could be accomplished within the limits assigned to it, for it is evident that the writer has had to contend with the difficulty so imposed upon him. Notwithstanding this, it will be found to contain much original observation and remark; for instance, in regard to the term Perpendicular, applied by Rickman to the third style into which he subdivides Gothic, it is objected, that Horizontal would be equally, if not more, applicable to it, inasmuch as the numerous transoms to windows, square-headed labels to doorways, &c., produce as many horizontal lines, as the mullions to windows, and ornamental panellings do perpendicular ones.

It is difficult to select any extract by way of specimen, unless it be the conclusion, where the characteristics of Grecian and Gothic architecture are thus summed up:—"*Grecian:* columns and their entablature are the chief sources of decoration, and limit the height of the building, as a second order cannot, with propriety, be placed above another. *Gothic:* columns, subordinate members; never used, except to support arches; and, in the latter styles, are mere ornamental shafts attached to piers. *Grecian:* colonnades seldom employed, except externally. *Gothic:* ranges of open arches, applied only internally. There being nothing analogous to a Grecian portico, some porches have merely an open arch in front, and when projecting from the building, are closed at the sides. Externally, open arches are introduced only in upper galvins, and those are of very rare occurrence; or as a cloister, not projecting from, but within, the lower part of the building. *Grecian:* lofty proportions unattainable, even in the largest edifices, because the greater the number of columns, the lower will they appear in comparison with their length or breadth. *Gothic:* no restraint as to loftiness, that not being regulated by width, either of the whole front, or any of its parts. *Grecian:* the pitch of a pediment must be governed by its span, since its height must in no case greatly exceed the depth of the entablature; consequently, the greater the number of the columns placed beneath it, the lower it must be, and the lower the proportions of the whole front. *Gothic:* gables may be made of any pitch, just as best accords with construction or composition of the design." Various other distinctive peculiarities of the respective styles are thus contrasted together, in such manner as to prove highly instructive, by calling attention to them, and impressing them on the mind of the reader.

PROFESSOR PUGIN'S FIRST LECTURE.

WELBY PUGIN has just made his debut in a new character, viz., that of Professor of Ecclesiastical Antiquities, at St. Mary's College, Oscott; and, as it was to be expected, his first appearance upon that stage has turned out a marvellous one. Marvellous at least was his lecture, which has been printed pro bono publico in the Catholic Magazine for April. It was both frothy and foaming—frothy in argument, foaming with bile and vituperation against the Protestant Church, and against all his brother architects of the present day, whom he denounces *en masse*—perhaps when he should have been at mass—as a set of tasteless, mercenary *miserables*, insolent, ignorant pretenders, and downright charlatans.

It is greatly to be feared, that the learned Professor is in a most violent bilious fever, for his bile conjures up images to his imagination that again excite his bile till it boils quite over, sending forth a most awful hissing. For instance, it moves him quite into a fit of madness on one occasion, during which he beholds a vision of "spruce parsons" attended by liveried minions, and whose tables actually "groan under the weight of delicacies to pamper their palled appe-

tites." According, therefore, to him, the English Church is suffering from plethora, and its "parsons" are likely to die of surfeits, unless made to disgorge their good things into the bosom of Rome. A few Romish fasts would, no doubt, be of very great service both to them and their "liveried minions," who might be delivered over to the dominions of either Cerberus, or the Cerberus-crowned Majesty of Rome.

That the Professor himself is a stanch advocate for fasts we can readily believe, seeing how very fast indeed his tongue runs on, when, fancying himself no less than an architectural Pope, he fulminates his bulls and bullying tirades against modern English architects. Ecce signum: "They have," exclaims our orthodox Professor, "a set of stale ideas, drawn from borrowed sources, which they keep as stock patterns, and transpose to serve all purposes. They do not understand any style, but profess themselves masters of all, and will undertake any absurdity to suit the taste of an individual, provided they are well paid." In merely a first lecture, this promises well for the future. Let us not, however, omit the following *beau ideal* of a modern English architect, as hit off by our smelfungus Professor:—"In fine, he draws, looks, thinks, and lives, at so much per cent." It would seem that Protestant architects are about as mercenary as Catholic priests, who would suffer Catholic souls to fry in purgatory until doomsday, unless paid for praying them out of it; whereas, if they themselves really believe there is any efficacy at all in their prayers, they ought to bestow them, whether paid for so doing or not.

As far as Catholicism or Protestantism are concerned in the matter, we believe that far more egregious architectural absurdities may be laid to the charge of the former than of the latter. Has Protestant England ever produced aught that can rival the extravagancies of Borromini, or the absurd freaks of Padre Guarini, who even out-Borromined Borromini himself? If there be that connexion between religious and architectural heterodoxy, which our bilious Professor more than insinuates—for it constitutes, in fact, the gist of his whole lecture—his Holiness would do well to blow up St. Peter's, and many other churches at Rome, were it merely to escape a blowing up from the orthodox Pugin. Without disparaging what is really good in Italian architecture, it may be affirmed, that there is hardly an absurdity conceivable that has not been perpetrated by the architects of Catholic Italy; and to Italy may be added most other Catholic countries. We must admit, that there is no want of ornament in their churches; yet very much of it is in the most peurile and gewgaw taste, hardly a degree superior to that displayed in a Bartholomew Fair booth.
